TRANSMOUNTAIN

CELEBRATING 60 YEARS OF SERVICE 1953 to 2013

Trans Mountain Pipeline ULC

Trans Mountain Expansion Project

An Application Pursuant to Section 52 of the National Energy Board Act

December 2013

Volume 5a ESA - Biophysical

KINDER MORGAN CANADA

NATIONAL ENERGY BOARD

IN THE MATTER OF

**the *National Energy Board Act*,
R.S.C. 1985, c. N-7, as amended, ("*NEB Act*")
and the Regulations made thereunder;**

AND IN THE MATTER OF

**the *Canadian Environmental Assessment Act*, 2012,
S.C. 2012, c. 37, as amended,
and the Regulations made thereunder;**

AND IN THE MATTER OF

**an application by Trans Mountain Pipeline ULC
as General Partner of Trans Mountain Pipeline L.P.
(collectively "Trans Mountain")
for a Certificate of Public Convenience and Necessity and
other related approvals pursuant to Part III of the *NEB Act***

APPLICATION BY TRANS MOUNTAIN FOR APPROVAL OF THE TRANS MOUNTAIN EXPANSION PROJECT

December 2013

**To: The Secretary
The National Energy Board
444 — 7th Avenue SW
Calgary, AB T2P 0X8**

Trans Mountain Expansion Project
Application Pursuant to Section 52 of the *National Energy Board Act*

Guide to the Application

Application	
Transmittal - Letter to the National Energy Board	
Volume 1	Summary
Volume 2	Project Overview, Economics and General Information
Volume 3A	Public Consultation
Volume 3B	Aboriginal Engagement
Volume 3C	Landowner Relations
Volume 4A	Project Design and Execution – Engineering
Volume 4B	Project Design and Execution – Construction
Volume 4C	Project Design and Execution – Operations and Maintenance
Volume 5A	**Environmental and Socio-Economic Assessment – Biophysical**
Volume 5B	Environmental and Socio-Economic Assessment – Socio-Economic
Volume 5C	Environmental and Socio-Economic Assessment – Biophysical Technical Reports
Volume 5D	Environmental and Socio-Economic Assessment – Socio-Economic Technical Reports
Volume 6A	Environmental Compliance
Volume 6B	Pipeline Environmental Protection Plan
Volume 6C	Facilities Environmental Protection Plan
Volume 6D	Westridge Marine Terminal Environmental Protection Plan
Volume 6E	Environmental Alignment Sheets
Volume 7	Risk Assessment and Management of Pipeline and Facility Spills
Volume 8A	Marine Transportation
Volume 8B	Marine Environmental and Socio-Economic Technical Reports
Volume 8C	TERMPOL Reports

This volume contains:

Volume 5A			
Section 1.0	Introduction	Section 6.0	Environmental Setting for Facilities
Section 2.0	Project Description	Section 7.0	Environmental Effects Assessment
Section 3.0	Public Consultation, Aboriginal Engagement and Landowner Relations	Section 8.0	Cumulative Effects Assessment
		Section 9.0	Supplemental Studies
Section 4.0	Corridor and Facility Site Selection	Section 10.0	Follow-up
Section 5.0	Environmental Setting for the Pipeline	Section 11.0	Conclusions

NEB FILING MANUAL CHECKLIST

CHAPTER 3 – COMMON INFORMATION REQUIREMENTS

Filing #	Filing Requirement	In Application? References	Not in Application? Explanation
3.1 Action Sought by Applicant			
1.	Requirements of s.15 of the Rules.	Volume 1 Section 1.1	---
3.2 Application or Project Purpose			
1.	Purpose of the proposed project.	Volume 2 Section 1.1	---
3.4 Consultation		Volumes 3A, 3B, 3C; Volumes 5A, 5B Section 3; Volume 8A Section 3	--
3.4.1 Principles and Goals of Consultation			
1.	The corporate policy or vision.	Volume 3A Section 1.2.1 Volume 3B Section 1.2.1	--
2.	The principles and goals of consultation for the project.	Volume 3A Section 1.2.2 Volume 3B Section 1.2.2 Volume 5A Section 3.2.1 Volume 5B Section 3.2.1	--
3.	A copy of the Aboriginal protocol and copies of policies and principles for collecting traditional use information, if available.	Volume 3B Section 1.3.5	--
3.4.2 Design of Consultation Program			
1.	The design of the consultation program and the factors that influenced the design.	Volume 3A Section 1.3 Volume 3B Section 1.3 Volume 5A Section 3.1.1, 3.2.2 Volume 5B Section 3.1.1, 3.2.2	--
3.4.3 Implementing a Consultation Program			
1.	The outcomes of the consultation program for the project.	Volume 3A Section 1.7 Volume 3B Section 1.5 Table 1.5.1 Volume 5A Section 3.1.5, 3.2.4 Volume 5B Section 3.1.5, 3.2.4	--
3.4.4 Justification for Not Undertaking a Consultation Program			
2.	The application provides justification for why the applicant has determined that a consultation program is not required for the project.	N/A	N/A
3.5 Notification of Commercial Third Parties			
1.	Confirm that third parties were notified.	Volume 2 Section 3.2.2	--
2.	Details regarding the concerns of third parties.	Volume 2 Section 3.2.2	--
3.	List the self-identified interested third parties and confirm they have been notified.	N/A	N/A
4.	If notification of third parties is considered unnecessary, an explanation to this effect.	N/A	N/A

CHAPTER 4 – SECTIONS 4.1 AND 4.2: COMMON REQUIREMENTS FOR PHYSICAL PROJECTS

Filing #	Filing Requirement	In Application? References	Not in Application? Explanation
4.1 Description of the Project			--
1.	The project components, activities and related undertakings.	Volume 2 Section 2.0; Volume 4A	--
2.	The project location and criteria used to determine the route or site.	Volume 2 Section 4.0; Volume 4A	--
3.	How and when the project will be carried out.	Volume 2 Section 2.3; Volume 4B Section 2.0	--
4.	Description of any facilities, to be constructed by others, required to accommodate the proposed facilities.	N/A	N/A
5.	An estimate of the total capital costs and incremental operating costs, and changes to abandonment cost estimates.	Volume 2 Section 2.9	--
6.	The expected in-service date.	Volume 2 Section 1.1; Volume 4B Section 2.1	--
4.2 Economic Feasibility, Alternatives and Justification			
4.2.1 Economic Feasibility			
1.	Describe the economic feasibility of the project.	Volume 2 Section 3.5	--
4.2.2 Alternatives			
1.	Describe the need for the project, other economically-feasible alternatives to the project examined, along with the rationale for selecting the applied for project over these other possible options.	Volume 2 Section 3.0; Volume 8A Section 2.2	--
2.	Describe and justify the selection of the proposed route and site including a comparison of the options evaluated using appropriate selection criteria.	Volume 2 Section 4.0; Volume 8A Section 2.2	--
3.	Describe the rationale for the chosen design and construction methods. Where appropriate, describe any alternative designs and methods evaluated and explain why these other options were eliminated.	Volume 2 Section 4.0; Volume 8A Section 2.2	--
4.2.3 Justification			
1.	Provide a justification for the proposed project	Volume 2 Section 3.4	--

GUIDE A – A.1 ENGINEERING

Filing #	Filing Requirement	In Application? References	Not in Application? Explanation
A.1.1 Engineering Design Details			
1.	Fluid type and chemical composition.	Volume 4A Section 3.1.1	--
2.	Line pipe specifications.	Volume 4A Section 3.2.8	--
3.	Pigging facilities specifications.	Volume 4A Section 3.3.1, 3.3.2	--
4.	Compressor or pump facilities specifications.	Volume 4A Section 3.4	--
5.	Pressure regulating or metering facilities specifications.	Volume 4A Section 3.5	--
6.	Liquid tank specifications, or other commodity storage facilities.	Volume 4A Section 3.4	--
7.	New control system facilities specifications.	Volume 4A Section 3.3	--
8.	Gas processing, sulphur or LNG plant facilities specifications.	N/A	N/A
9.	Technical description of other facilities not mentioned above.	N/A	N/A
10.	Building dimensions and uses.	Volume 4A Section 3.3, 3.4, 3.5	--
11.	If project is a new system that is a critical source of energy supply, a description of the impact to the new system capabilities following loss of critical component.	N/A	N/A
A.1.2 Engineering Design Principles			
1.	Confirmation project activities will follow the requirements of the latest version of CSA Z662.	Volume 4A Section 2.2	--
2.	Provide a statement indicating which Annex is being used and for what purpose	Volume 4A Section 2.3	--
3.	Statement confirming compliance with OPR or PPR.	Volume 4A Section 2.1	--
4.	Listing of all primary codes and standards, including version and date of issue.	Volume 4A Section 2, Table 5.1.1	--
5.	Confirmation that the project will comply with company manuals and confirm manuals comply with OPR/PPR and codes and standards.	Volume 4A Section 2.6, Table 5.1.2	--
6.	Any portion of the project a non-hydrocarbon commodity pipeline system? Provide a QA program to ensure the materials are appropriate for their intended service.	N/A – all hydrocarbons	N/A
7.	If facility subject to conditions not addressed in CSA Z662: • Written statement by qualified professional engineer • Description of the designs and measures required to safeguard the pipeline	Volume 4A Section 2.9	--
8.	If directional drilling involved: • Preliminary feasibility report • Description of the contingency plan	Volume 4A Section 2.12	--
9.	If the proposed project involves the reuse of materials, provide an engineering assessment in accordance with CSA Z662 that indicates its suitability for the intended service.	Volume 4A, Section 2.7	--
10.	If new materials are involved, provide material supply chain information, in tabular format.	Volume 4A Section 2.7	
11.	If reuse of material is involved, provide an engineering assessment in accordance with CSA Z662 that indicates its suitability for the intended service.	Volume 4A, Section 2.7	--
A.1.3 Onshore Pipeline Regulations			
1.	Designs, specifications programs, manuals, procedures, measures or plans for which no standard is set out in the OPR or PPR.	--	Existing standards will be followed
2.	A quality assurance program if project non-routine or incorporates unique challenges due to geographical location.	--	No unique challenges
3.	If welding performed on a liquid-filled pipeline that has a carbon equivalent of 0.50% or greater and is a permanent installation: • Welding specifications and procedures • Results of procedure qualification tests	--	Welding on liquid filled pipe will not be conducted

GUIDE A – A.2 ENVIRONMENTAL AND SOCIO-ECONOMIC ASSESSMENT

The following table identifies where information requested in the National Energy Board (NEB) Filing Manual Guide A – A.2 Environmental and Socio-economic Assessment checklist may be found in the various volumes of the Application for the Trans Mountain Expansion Project.

Filing #	Filing Requirement	In Application? References	Applicable Marine Transportation Elements	Not in Application? Explanation
A.2.5 Description of the Environmental and Socio-Economic Setting				
1.	Identify and describe the current biophysical and socio-economic setting of each element (*i.e.*, baseline information) in the area where the project is to be carried out.	Volume 5A: ESA - Biophysical • Sections 5.0 and 6.0 Volume 5B: ESA - Socio-Economic • Sections 5.0 and 6.0 Volume 5C: ESA - Biophysical Technical Reports Volume 5D: ESA - Socio-Economic Technical Reports	Volume 8A: Marine Transportation • Section 4.2 Volume 8B: Technical Reports	---
2.	Describe which biophysical or socio-economic elements in the study area are of ecological, economic, or human importance and require more detailed analysis taking into account the results of consultation (see Table A-1 for examples). Where circumstances require more detailed information in an ESA see: i. Table A-2 – Filing Requirements for Biophysical Elements; or ii. Table A-3 – Filing Requirements for Socio-economic Elements.	Volume 5A: ESA - Biophysical • Sections 5.0 and 6.0 Volume 5B: ESA - Socio-Economic • Sections 5.0 and 6.0 Volume 5C: ESA - Biophysical Technical Reports Volume 5D: ESA - Socio-Economic Technical Reports	Volume 8A: Marine Transportation • Section 4.2 Volume 8B: Technical Reports	---
3.	Provide supporting evidence (*e.g.*, references to scientific literature, field studies, local and traditional knowledge, previous environmental assessment and monitoring reports) for: • information and data collected; • analysis completed; • conclusions reached; and • the extent of professional judgment or experience relied upon in meeting these information requirements, and the rationale for that extent of reliance.	Volume 5A: ESA - Biophysical • Sections 5.0 and 6.0 Volume 5B: ESA - Socio-Economic • Sections 5.0 and 6.0 Volume 5C: ESA - Biophysical Technical Reports Volume 5D: ESA - Socio-Economic Technical Reports	Volume 8A: Marine Transportation • Section 4.2 Volume 8B: Technical Reports	---
4.	Describe and substantiate the methods used for any surveys, such as those pertaining to wildlife, fisheries, plants, species at risk or species of special status, soils, heritage resources or traditional land use, and for establishing the baseline setting for the atmospheric and acoustic environment.	Volume 5A: ESA - Biophysical • Sections 5.0 and 6.0 Volume 5B: ESA - Socio-Economic • Sections 5.0 and 6.0 Volume 5C: ESA - Biophysical Technical Reports Volume 5D: ESA - Socio-Economic Technical Reports	Volume 8A: Marine Transportation • Section 4.2 Volume 8B: Technical Reports	---
5.	Applicants must consult with other expert federal, provincial or territorial departments and other relevant authorities on requirements for baseline information and methods.	Volume 5A: ESA - Biophysical • Sections 3.0, 5.0 and 6.0 Volume 5B: ESA - Socio-Economic • Sections 3.0, 5.0 and 6.0 Volume 5C: ESA - Biophysical Technical Reports Volume 5D: ESA - Socio-Economic Technical Reports	Volume 8A: Marine Transportation • Sections 3.0 and 4.2 Volume 8B: Technical Reports	---

Filing #	Filing Requirement	In Application? References	Applicable Marine Transportation Elements	Not in Application? Explanation
A.2.6 Effects Assessment				
Identification and Analysis of Effects				
1.	Describe the methods used to predict the effects of the project on the biophysical and socio-economic elements, and the effects of the environment on the project (*i.e.*, changes to the Project caused by the environment).	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0 Volume 7: Risk Assessment and Management of Pipeline and Facility Spills • Sections 6.0, 7.0 and 8.0 • Technical Reports	Volume 8A: Marine Transportation • Sections 4.3, 5.5 and 5.6	---
2.	Predict the effects associated with the proposed project, including those that could be caused by construction, operations, decommissioning or abandonment, as well as accidents and malfunctions. Also include effects the environment could have on the project. For those biophysical and socio-economic elements or their valued components that require further analysis (see Table A-1), provide the detailed information outlined in Tables A-2 and A-3.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0 Volume 5C: ESA - Biophysical Technical Reports Volume 5D: ESA - Socio-Economic Technical Reports Volume 7: Risk Assessment and Management of Pipeline and Facility Spills • Sections 6.0, 7.0 and 8.0 • Technical Reports	Volume 8A: Marine Transportation • Sections 4.3, 5.6 and 5.7 Volume 8B: Technical Reports	---
Mitigation Measures for Effects				
1.	Describe the standard and project specific mitigation measures and their adequacy for addressing the project effects, or clearly reference specific sections of company manuals that provide mitigation measures. Ensure that referenced manuals are current and filed with the NEB.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0 Volume 5C: ESA - Biophysical Technical Reports Volume 5D: ESA - Socio-Economic Technical Reports Volume 6B: Pipeline Environmental Protection Plan (EPP) Volume 6C: Facilities EPP Volume 6D: Westridge Marine Terminal EPP Volume 6E: Environmental Alignment Sheets Volume 7: Risk Assessment and Management of Pipeline and Facility Spills • Sections 2.0, 3.0, 4.0, 6.0, 7.0, and 8.0 • Technical Reports	Volume 8A: Marine Transportation • Sections 4.3, 5.1, 5.3, 5.6 and 5.7 Volume 8B: Technical Reports	---
2.	Ensure that commitments about mitigative measures will be communicated to field staff for implementation through an Environmental Protection Plan.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0 Volume 6A: Environmental Compliance Volume 6B: Pipeline EPP Volume 6C: Facilities EPP Volume 6D: Westridge Marine Terminal EPP Volume 6E: Environmental Alignment Sheets Volume 7: Risk Assessment and Management of Pipeline and Facility Spills • Sections 2.0, 3.0, 4.0, 6.0, 7.0 and 8.0	Volume 8A: Marine Transportation • Sections 4.3, 5.1, 5.3, 5.6 and 5.7	---

Filing #	Filing Requirement	In Application? References	Applicable Marine Transportation Elements	Not in Application? Explanation
3.	Describe plans and measures to address potential effects of accidents and malfunctions during construction and operation of the project.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0 Volume 6B: Pipeline EPP Volume 6C: Facilities EPP Volume 6D: Westridge Marine Terminal EPP Volume 7: Risk Assessment and Management of Pipeline and Facility Spills • Sections 2.0, 4.0, 6.0, 7.0 and 8.0	Volume 8A: Marine Transportation • Sections 4.3, 5.1, 5.3, 5.6 and 5.7	---
Evaluation of Significance				
1.	After taking into account any appropriate mitigation measures, identify any remaining residual effects from the project.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0	Volume 8A: Marine Transportation • Section 4.3	---
2.	Describe the methods and criteria used to determine the significance of remaining adverse effects, including defining the point at which any particular effect on a valued component is considered “significant”.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0	Volume 8A: Marine Transportation • Section 4.3	---
3.	Evaluate significance of residual adverse environmental and socio-economic effects against the defined criteria.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0	Volume 8A: Marine Transportation • Section 4.3	---
4.	Evaluate the likelihood of significant, residual adverse environmental and socio-economic effects occurring and substantiate the conclusions made.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0	Volume 8A: Marine Transportation • Section 4.3	---
A.2.7 Cumulative Effects Assessment				
Scoping and Analysis of Cumulative Effects				
1.	Identify the valued components for which residual effects are predicted, and describe and justify the methods used to predict any residual results.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
2.	For each valued component where residual effects have been identified, describe and justify the spatial and temporal boundaries used to assess the potential cumulative effects.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
3.	Identify other physical works or activities that have been or will be carried out within the identified spatial and temporal boundaries for the cumulative effects assessment.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
4.	Identify whether the effects of those physical works or activities that have been or will be carried out would be likely to produce effects on the valued components within the identified spatial and temporal boundaries.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---

Filing #	Filing Requirement	In Application? References	Applicable Marine Transportation Elements	Not in Application? Explanation
5.	Where other physical works or activities may affect the valued components for which residual effects from the applicant's proposed project are predicted, continue the cumulative effects assessment, as follows: • consider the various components, phases and activities associated with the applicant's project that could interact with other physical work or activities; • provide a description of the extent of the cumulative effects on valued components; and • where professional knowledge or experience is cited, explain the extent to which professional knowledge or experience was relied upon and justify how the resulting conclusions or decisions were reached.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
Mitigation Measures for Cumulative Effects				
1.	Describe the general and specific mitigation measures, beyond project-specific mitigation already considered, that are technically and economically feasible to address any cumulative effects.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
Applicant's Evaluation of Significance of Cumulative Effects				
1.	After taking into account any appropriate mitigation measures for cumulative effects, identify any remaining residual cumulative effects.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
2.	Describe the methods and criteria used to determine the significance of remaining adverse cumulative effects, including defining the point at which each identified cumulative effect on a valued component is considered "significant".	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
3.	Evaluate the significance of adverse residual cumulative effects against the defined criteria.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
4.	Evaluate the likelihood of significant, residual adverse cumulative environmental and socio-economic effects occurring and substantiate the conclusions made.	Volume 5A: ESA - Biophysical • Section 8.0 Volume 5B: ESA - Socio-Economic • Section 8.0	Volume 8A: Marine Transportation • Section 4.4	---
A.2.8 Inspection, Monitoring and Follow-up				
1.	Describe inspection plans to ensure compliance with biophysical and socio-economic commitments, consistent with Sections 48, 53 and 54 of the *NEB Onshore Pipeline Regulations (OPR).*	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0 Volume 6A: Environmental Compliance Volume 6B: Pipeline EPP Volume 6C: Facilities EPP Volume 6D: Westridge Marine Terminal EPP	Volume 8A: Marine Transportation • Section 4.3	---
2.	Describe the surveillance and monitoring program for the protection of the pipeline, the public and the environment, as required by Section 39 of the *NEB OPR*.	Volume 5A: ESA - Biophysical • Section 7.0 Volume 5B: ESA - Socio-Economic • Section 7.0 Volume 6A: Environmental Compliance Volume 6B: Pipeline EPP Volume 6C: Facilities EPP Volume 6D: Westridge Marine Terminal EPP	Volume 8A: Marine Transportation • Section 4.3	---

Filing #	Filing Requirement	In Application? References	Applicable Marine Transportation Elements	Not in Application? Explanation
3.	Consider any particular elements in the Application that are of greater concern and evaluate the need for a more in-depth monitoring program for those elements.	Volume 5A: ESA - Biophysical • Sections 9.0 and 10.0 Volume 5B: ESA - Socio-Economic • Sections 9.0 and 10.0 Volume 6A: Environmental Compliance Volume 6B: Pipeline EPP (Socio-Economic Management Plan of Appendix C)	Volume 8A: Marine Transportation • Section 4.5	---
4.	For *Canadian Environmental Assessment (CEA) Act, 2012* designated projects, identify which elements and monitoring procedures would constitute follow-up under the *CEA Act, 2012*.	Volume 5A: ESA - Biophysical • Section 10.0 Volume 5B: ESA - Socio-economic • Section 10.0	N/A	---

GUIDE A – A.3 ECONOMICS

Filing #	Filing Requirement	In Application? References	Not in Application? Explanation
A.3.1 Supply			
1.	A description of each commodity.	Volume 2 Section 3.1.1	--
2.	A discussion of all potential supply sources.	Volume 2 Section 3.3.2	--
3.	Forecast of productive capacity over the economic life of the facility.	Volume 2 Sections 3.3.1, 3.4.1	
4.	For pipelines with contracted capacity, a discussion of the contractual arrangements underpinning supply.	Volume 2 Section 3.3.2	--
A.3.2 Transportation Matters			
Pipeline Capacity			
1.	In the case of expansion provide: • Pipeline capacity before and after and size of increment • Justification that size of expansion is appropriate	Volume 2 Sections 1.1, 2.1, 3.5	--
2.	In case of new pipeline, justification that size of expansion is appropriate given available supply.	N/A – expansion	N/A
Throughput			
1.	For pipelines with contracted capacity, information on contractual arrangements.	Volume 2 Section 3.2.1	--
2.	For non-contract carrier pipelines, forecast of annual throughput volumes by commodity type, receipt location and delivery destination over facility life.	N/A	N/A
3.	If project results in an increase in throughput: • theoretical and sustainable capabilities of the existing and proposed facilities versus the forecasted requirements • flow formulae and flow calculations used to determine the capabilities of the proposed facilities and the underlying assumptions and parameters	Volume 2 Section 3.1	--
4.	If more than one type of commodity transported, a discussion pertaining to segregation of commodities including potential contamination issues or cost impacts.	N/A	N/A
A.3.3 Markets			
1.	Provide an analysis of the market in which each commodity is expected to be used or consumed.	Volume 2 Section 3.4.2	--
2.	Provide a discussion of the physical capability of upstream and downstream facilities to accept the incremental volumes that would be received and delivered.	Volume 2 Section 3.4.2	--
A.3.4 Financing			
1.	Evidence that the applicant has the ability to finance the proposed facilities.	Volume 2 Section 3.2.2	--
2.	Estimated toll impact for the first full year that facilities are expected to be in service.	Volume 2 Section 3.2.1	--
3.	Confirmation that shippers have been apprised of the project and toll impact, their concerns and plans to address them.	Volume 2 Section 3.2.1	--
4.	Additional toll details for applications with significant toll impacts.	Volume 2 Section 3.2.1	
A.3.5 Non-NEB Regulatory Approvals			
1.	Confirm that all non-NEB regulatory approvals required to allow the applicant to meet its construction schedule, planned in-service date and to allow the facilities to be used and useful are or will be in place.	Volume 2 Section 1.5	--
2.	If any of the approvals referred to in #1 may be delayed, describe the status of those approval(s) and provide an estimation of when the approval is anticipated.	Volume 2 Section 1.5	--

GUIDE A – A.4 LANDS INFORMATION

Filing #	Filing Requirement	In Application? References	Not in Application? Explanation
A.4.1 Land Areas			
1.	• Width of right-of-way and locations of any changes to width • Locations and dimensions of known temporary work space and drawings of typical dimensions • Locations and dimensions of any new lands for facilities	Volume 2 Section 5.2	--
A.4.2 Land Rights			
1.	The type of lands rights proposed to be acquired for the project.	Volume 2 Section 5.3	--
2.	The relative proportions of land ownership along the route of the project.	Volume 2 Section 5.3.2	--
3.	Any existing land rights that will be required for the project.	Volume 2 Section 5.4	--
A.4.3 Lands Acquisition Process			
1.	The process for acquiring lands.	Volume 2 Section 5.4.1, 5.4.2	--
2.	The timing of acquisition and current status.	Volume 2 Section 5.4.3	--
3.	The status of service of section 87(1) notices.	Volume 2 Section 5.4.4	--
A.4.4 Land Acquisition Agreements			
1.	A sample copy of each form of agreement proposed to be used pursuant to section 86(2) of the NEB Act.	Volume 2 Section 5.4.2	--
2.	A sample copy of any proposed fee simple, work space, access or other land agreement.	Volume 2 Section 5.5.2	--
A.4.5 Section 87 Notices			
1.	A sample copy of the notice proposed to be served on all landowners pursuant to section 87(1) of the NEB Act.	Volume 2 Section 5.4.4, Appendix D	--
2.	Confirmation that all notices include a copy of Pipeline Regulation in Canada: A Guide for Landowners and the Public.	Volume 2 Section 5.4.4	--
A.4.6 Section 58 Application to Address a Complaint			
1.	The details of the complaint and describe how the proposed work will address the complaint.	N/A	N/A

Ph: 403-265-2885

EXECUTIVE SUMMARY

This biophysical component of the Environmental and Socio-Economic Assessment (ESA) was completed in support of the proposed Trans Mountain Expansion Project (referred to as “TMEP” or “the Project”). (The socio-economic component of the ESA is found in the companion Volume 5B.)

Application is being made by Trans Mountain Pipeline ULC (Trans Mountain), a Canadian corporation with its head office located in Calgary, Alberta, pursuant to Section 52 of the *National Energy Board Act* (*NEB Act*) for the TMEP.

The proposed expansion will, in essence, comprise the following.

- Pipeline segments that complete a twinning (or “looping”) of the pipeline in Alberta and British Columbia with about 987 km of new buried pipeline.
- New and modified facilities, including pump stations and tanks.
- Three new berths at the Westridge Marine Terminal in Burnaby, BC, each capable of handling Aframax class vessels.

The Project will require a NEB Certificate of Public Convenience and Necessity (CPCN) pursuant to Section 52 of the *NEB Act*. In addition, according to the Regulations Designating Physical Activities, the Project is a designated project under the *Canadian Environmental Assessment Act, 2012* (*CEA Act, 2012*). The ESA considers the mandatory factors listed in Section 19(1) of the *CEA Act, 2012*, the factors listed in the NEB *Filing Manual* (NEB 2013a), and pertinent issues and concerns identified through consultation and engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public.

In addition, the ESA addresses the NEB’s List of Issues (July 29, 2013) for the Project (NEB 2013b) provided below. Issues 4 and 5 of this list specifically informed the ESA.

1. *The need for the proposed project.*
2. *The economic feasibility of the proposed project.*
3. *The potential commercial impacts of the proposed project.*
4. *The potential environmental and socio-economic effects of the proposed project, including any cumulative environmental effects that are likely to result from the project, including those required to be considered by the NEB’s Filing Manual.*
5. *The potential environmental and socio-economic effects of marine shipping activities that would result from the proposed project, including the potential effects of accidents or malfunctions that may occur (addressed in Volume 8A).*
6. *The appropriateness of the general route and land requirements for the proposed project.*
7. *The suitability of the design of the proposed project.*
8. *The terms and conditions to be included in any approval the Board may issue.*
9. *Potential impacts of the project on Aboriginal interests.*
10. *Potential impacts of the project on landowners and land use.*
11. *Contingency planning for spills, accidents or malfunctions, during construction and operation of the project.*
12. *Safety and security during construction of the proposed project and operation of the project, including emergency response planning and third-party damage prevention.*

The Board does not intend to consider the environmental and socio-economic effects associated with upstream activities, the development of oil sands, or the downstream use of the oil transported by the pipeline.

Project Overview

Trans Mountain Pipeline ULC (Trans Mountain) is a Canadian corporation with its head office located in Calgary, Alberta. Trans Mountain is a general partner of Trans Mountain Pipeline L.P., which is operated by Kinder Morgan Canada Inc. (KMC), and is fully owned by Kinder Morgan Energy Partners, L.P. Trans Mountain is the holder of the National Energy Board (NEB) certificates for the Trans Mountain pipeline system (TMPL system).

The TMPL system commenced operations 60 years ago and now transports a range of crude oil and petroleum products from Western Canada to locations in central and southwestern British Columbia (BC), Washington State and offshore. The TMPL system currently supplies much of the crude oil and refined products used in BC. The TMPL system is operated and maintained by staff located at Trans Mountain's regional and local offices in Alberta (Edmonton, Edson, and Jasper) and BC (Clearwater, Kamloops, Hope, Abbotsford, and Burnaby).

The TMPL system has an operating capacity of approximately 47,690 m^3/d (300,000 bbl/d) using 23 active pump stations and 40 petroleum storage tanks. The expansion will increase the capacity to 141,500 m^3/d (890,000 bbl/d).

The proposed expansion will comprise the following.

- Pipeline segments that complete a twinning (or "looping") of the pipeline in Alberta and BC with about 987 km of new buried pipeline.
- New and modified facilities, including pump stations and tanks.
- Three new berths at the Westridge Marine Terminal in Burnaby, BC, each capable of handling Aframax class vessels.

The expansion has been developed in response to requests for service from Western Canadian oil producers and West Coast refiners for increased pipeline capacity in support of growing oil production and access to growing West Coast and offshore markets. NEB decision RH-001-2012 reinforces market support for the expansion and provides Trans Mountain the necessary economic conditions to proceed with design, consultation, and regulatory applications.

Application is being made pursuant to Section 52 of the *National Energy Board Act* (*NEB Act*) for the proposed Trans Mountain Expansion Project (referred to as "TMEP" or "the Project"). The NEB will undertake a detailed review and hold a Public Hearing to determine if it is in the public interest to recommend a Certificate of Public Convenience and Necessity (CPCN) for construction and operation of the Project. Subject to the outcome of the NEB Hearing process, Trans Mountain plans to begin construction in 2016 and go into service in 2017.

Trans Mountain has embarked on an extensive program to engage Aboriginal communities and to consult with landowners, government agencies (*e.g.*, regulators and municipalities), stakeholders, and the general public. Information on the Project is also available at www.transmountain.com.

The scope of the Project will involve:

- using existing active 610 mm (NPS 24) and 762 mm (NPS 30) OD buried pipeline segments;
- constructing three new 914 mm (NPS 36) OD buried pipeline segments totalling approximately 987 km:
  - Edmonton to Hinton – 339.4 km
  - Hargreaves to Darfield – 279.4 km
  - Black Pines to Burnaby – 367.9 km;

- reactivating two 610 mm (NPS 24) OD buried pipeline segments that have been maintained in a deactivated state:
  - Hinton to Hargreaves – 150 km
  - Darfield to Black Pines – 43 km;
- constructing two, 3.6 km long 762 mm (NPS 30) OD buried delivery lines from the Burnaby Terminal to the Westridge Marine Terminal (the Westridge delivery lines);
- installing 23 new sending or receiving traps (16 on the Edmonton-Burnaby mainlines), for in-line inspection tools at nine existing sites and one new site;
- adding 35 new pumping units at 12 locations (*i.e.,* 11 existing and 1 new pump station site);
- reactivating the existing Niton Pump Station that has been maintained in a deactivated state;
- constructing 20 new tanks located at the terminals near Edmonton (5), Sumas (1) and Burnaby (14), preceded by demolition of 2 existing tanks near Edmonton (1) and Burnaby (1), for a net total of 18 tanks added to the system; and
- constructing one new dock complex, with a total of three Aframax-capable berths, as well as a utility dock (for tugs, boom deployment vessels, and emergency response vessels and equipment) at Westridge Marine Terminal, followed by the deactivation and demolition of the existing berth.

Volume 5A includes the biophysical (*i.e.*, environmental) component of the Environmental and Socio-economic Assessment (ESA) for the Project (*i.e.*, the proposed pipeline corridor and associated facilities, including the expansion of the Westridge Marine Terminal). The socio-economic component of the ESA for the Project is provided in Volume 5B. Volume 8A provides a discussion related to potential environmental and socio-economic effects of increased marine shipping activities as a result of the Project.

Public Consultation, Aboriginal Engagement and Landowner Relations

The Aboriginal engagement, stakeholder consultation, and landowner programs are designed to foster participation from the public who have an interest in the scope, activities and routing of the Project. Engagement and consultation touched on all aspects of the Project along the proposed pipeline corridor and associated facilities. Trans Mountain has reached out to community leaders, elected officials, environmental groups and the public to receive their input. Feedback was received from public open houses, workshops, one-on-one meetings, public presentations, online discussion and comment forums that have helped shape aspects of the Project. Key topics and issues were considered and incorporated into this volume where applicable.

Since April 2012, Trans Mountain has engaged with Aboriginal communities that may be affected by the Project or that may have an interest in the Project based on the proximity of their community, and their assertion of Aboriginal rights and title governing traditional and cultural use of the land along the proposed pipeline corridor to maintain a traditional lifestyle. A number of methods have been used to inform Aboriginal communities, obtain feedback and identify issues about the Project including: community gatherings; face-to face meetings; targeted interviews; formal and informal discussions; and distribution of Project letters, newsletters, GIS data, maps and fact sheets as well as through the collection of Traditional Ecological Knowledge (TEK) with participating Aboriginal communities during biophysical field studies for the Project, Traditional Land Use (TLU) and socio-economic studies. The results of these engagement efforts have contributed to the development of the environmental assessment, including mitigation measures. Trans Mountain is committed to the continuation of an effective engagement program that satisfies all parties.

Trans Mountain has met with essentially all landowners along the proposed pipeline corridor. Meetings comprised discussions about the Project in general as well as requests for consent for Project-specific surveys. The meetings also provided an opportunity for landowners to ask questions and identify concerns regarding the Project.

The questions, issues, or concerns raised by landowners were categorized most frequently related to compensation issues, land impacts, land values, site-specific pipeline location and issues related to the existing TMPL line (see Volume 3B).

Landowners of approximately 85% of all tracts of land raised no comments or concerns at this phase of the program. Of those that did comment within Alberta, concerns are about environmental and land-related issues. In BC, the primary concerns relate to environmental and compensation/financial issues. Trans Mountain will continue to respond to concerns and issues of each landowner or occupant.

Corridor and Facility Site Selection

More than two thirds of the length of the proposed pipeline corridor parallels the existing TMPL right-of-way in order to reduce the environmental effects and facilitate efficient pipeline operations. However, paralleling the existing TMPL right-of-way was not possible in all cases because of engineering, constructability, geotechnical, environmental, socio economic, Aboriginal concerns or other reasons. In these locations, potential alternative corridors were examined. While the proposed pipeline will generally require a construction right-of-way of 45 m, it was decided to study and apply for a wider corridor (generally 150 m) to accommodate locations where field information was unavailable due to lack of access to public lands or where input from the environmental, socio-economic, geotechnical or other disciplines would be beneficial to guide final placement of the proposed pipeline centreline and associated right-of-way. It is recognized that corridor and route refinement is an iterative process that will continue throughout the review phase of the Project as more information becomes available.

Site selection criteria were used to choose the sites where facility sites will be located, including the pump stations and associated power lines, storage tanks and mainline block valves. Site selection is primarily focused on reducing disturbance by using existing facility locations to the extent possible. Similar site selection criteria will be applied to select temporary facility sites and construction workspace.

Environmental Setting

Lands traversed by the proposed pipeline corridor include: agricultural lands (disturbed by plowing for cultivation); hay and tame pasture; areas of aspen woodlands and mixed aspen forest, treed pasture; native vegetation; urban; industrial; and parks. Numerous water bodies are crossed by and in proximity to the proposed pipeline corridor.

Environmental setting information along the proposed pipeline corridor and at facilities is provided in this volume for the following elements identified in the NEB *Filing Manual*:

- physical and meteorological environment;
- soil and soil productivity;
- water quality and quantity;
- air emissions;
- greenhouse gas emissions;
- acoustic environment;
- fish and fish habitat;
- wetland loss or alteration;
- vegetation;

- wildlife and wildlife habitat; and
- species at risk.

The environmental setting related to the Westridge Marine Terminal is also provided for marine elements, including marine sediment and water quality, marine fish and fish habitat, marine mammals, marine birds and marine species at risk. The environmental setting was compiled based on the following sources:

- geotechnical, soil, groundwater, air quality, GHG, acoustic, fish, wetland, vegetation, wildlife, marine sediment and water quality, marine fish and fish habitat and marine birds field studies conducted for the Project;
- existing published literature including topographic maps, aerial photography, scientific papers and reference books, as well as municipal, provincial and federal government maps, reports, interactive websites, guides, information letters, fact sheets and databases; and
- engagement with Aboriginal communities (including TLU and traditional marine resource use studies, socio-economic studies and biophysical field study participation) as well as consultation with landowners, regulatory authorities, stakeholders and the general public.

The settings for each element are discussed in the context of the Footprint of the Project, a Local Study Area and a Regional Study Area. The settings discuss existing conditions within defined element-specific spatial boundaries.

Information in the environmental setting is supported by several supporting studies provided in Volume 5C, including:

- Acid Rock Drainage and Metal Leaching Potential Technical Report;
- Soils Technical Report;
- Air Quality and Greenhouse Gas Technical Report;
- Terrestrial Noise and Vibration Technical Report;
- Groundwater Technical Report;
- Fisheries (Alberta) Technical Report;
- Fisheries (British Columbia) Technical Report;
- Wetland Evaluation Technical Report;
- Vegetation Technical Report;
- Wildlife Technical Report;
- Wildlife Modelling and Species Accounts Technical Report;
- Marine Sediment and Water Quality – Westridge Marine Terminal Technical Report;
- Marine Resources – Westridge Marine Terminal Technical Report (including marine fish and fish habitat and marine mammals); and
- Marine Birds – Westridge Marine Terminal Technical Report.

Environmental Effects Assessment

Environmental elements potentially interacting with the Project include: physical and meteorological environment; soil and soil productivity; water quality and quantity; air emissions; greenhouse gas emissions; acoustic environment; fish and fish habitat; wetland loss or alteration; vegetation; wildlife and wildlife habitat; marine sediment and water quality; marine fish and fish habitat; marine mammals; marine birds; and species at risk. The description of the environmental setting (current state of the environment) within the Project area was compared against the Project description to assess potential environmental effects that might be caused by the Project. For this assessment, one or more indicators (*i.e.*, a biophysical, social or economic property or variable that society considers to be important and is assessed to predict Project-related changes and focus the impact assessment on key issues, often referred to as Valued Ecosystem Components) were selected to describe the present and predicted future condition of an element. One or more measurement endpoints (measurable parameters) were identified for each indicator to allow quantitative or qualitative measurement of potential Project effects.

The assessment evaluates the environmental effects of the construction (including reactivation/modification), operation, decommissioning and abandonment phases of each component of the Project. The assessment method includes the following steps.

1. Describe the environmental setting.
2. Identify key environmental elements that could be affected.
3. Define the indicators and measurement endpoints to be used to assess each element.
4. Determine spatial and temporal boundaries for each element.
5. Identify potential environmental effects for each indicator.
6. Develop appropriate technically and economically feasible site-specific mitigation and, where warranted, restitution measures that are technically and economically feasible.
7. Predict anticipated residual effects.
8. Determine the significance of residual effects.

Environmental effects arising from potential accidents and malfunctions are also considered. However, large onshore spill scenarios (including Westridge Marine Terminal) and marine spills are discussed in Volumes 7 and 8A, respectively. Changes to the Project caused by the environment are also considered in this volume.

To ensure that the potential adverse environmental effects are eliminated or reduced during Project activities, general and site-specific mitigation measures have been recommended based upon current industry-accepted standards, consultation with regulatory authorities, interested groups and individuals, engagement with Aboriginal communities, and the professional judgment of the assessment team. Mitigation measures are presented in the Project-specific Environmental Protection Plans (EPPs) (Volumes 6B through 6D) and are developed from element-specific technical reports. In addition, various federal and provincial regulatory authorities, and industry-accepted standards and guidelines are considered in this assessment and are referenced for each element.

Most of the potential effects on environmental indicators arising from construction of the Project can be readily mitigated by standard environmental mitigation measures common to pipeline projects in similar settings. There are no situations that meet the criteria of a significant adverse residual environmental effect as defined in Section 7.1 of this volume. Consequently, the identified residual effects of construction and operation of the Project on environmental indicators will be not significant for the pipeline and facilities component of the Project.

The Project was evaluated with respect to the objectives and goals of relevant land and resource use management plans, municipal development plans and government policies of the communities, counties and regional districts traversed by the proposed pipeline corridor and facilities. The planning, design, construction and operation of the Project will be consistent with key actions or objectives of these plans. In addition, for each element, it was determined that the Project does not hinder the ability of the respective agency to fulfill the relevant goals or objectives of these plans.

Cumulative Effects Assessment

The Project may act cumulatively with existing activities and reasonably foreseeable developments in the vicinity of the Project including agriculture (*e.g.*, crop production and livestock grazing), forestry, recreational activities, transportation activities (*e.g.*, vehicle and rail traffic, road infrastructure and highway maintenance), utilities activities (*e.g.*, transmission lines and gas distribution lines), rural and urban residential and commercial development, and industrial, oil and gas, and mineral resources developments. Cumulative effects associated with the Project were evaluated on a conservative basis for the element under consideration. Most of the Project's contribution to cumulative effects within the element-specific LSAs and RSAs that are likely to occur, are anticipated to be reversible in the short to long-term and are generally of low to medium magnitude. There are no situations that would result in a significant adverse cumulative environmental effect, as defined in Section 7.1, for the pipeline and facilities component of the Project.

Supplemental Studies

Supplemental (ongoing) studies may be warranted as the route is refined and optimized. At some locations, access for environmental and resource surveys was also not available at the time of field study. In those situations, information on adjacent lands, desktop studies and professional judgment based on the team's familiarity with pipeline issues and mitigation were used to predict potential effects. Ongoing studies will support effects assessment predictions and refine and augment site-specific environmental protection planning. Land access was available at intervals in all segments of the entire proposed pipeline corridor. Studies are proposed for soil and soil productivity, fish and fish habitat, wetlands, vegetation and wildlife and wildlife habitat. If findings change or significantly different conditions are observed that information will be provided to the NEB. The respective scope and timing (field and reporting schedule) for the planned supplemental filings are described in Section 9.0.

Current mitigation, management and contingency plans have been conservatively developed to address the expected findings from the ongoing studies and have been based on professional judgment relying on continuity of adjoining land parcels for which comprehensive field studies have been completed. The additional study requirements are not anticipated to change the significance conclusions in Sections 7.0 and 8.0 of Volume 5A.

Follow-up

Under the *CEA Act, 2012* and as described in the NEB *Filing Manual*, a follow-up program is defined as a program to verify the accuracy of the environmental assessment of a designated project, and to determine the effectiveness of any mitigation measures. Based on Project knowledge and comprehensive field studies to date, the need for follow-up programs under the *CEA Act, 2012* have been identified for select wildlife species at risk and various indicators within the Socio-economic Management Plan. Trans Mountain plans to collect additional information in 2014 to inform and refine the mitigation strategies recommended in the Environmental Protection Plans.

Conclusion

The environmental assessment concludes that the proposed pipeline and associated facilities (*e.g.*, pump stations, terminals, Westridge Marine Terminal) does not result in significant adverse residual environmental effects as defined in Section 7.1. Consequently, the identified residual effects of construction and operation of the Project on environmental indicators will be not significant for the pipeline and facilities component of the Project.

The environmental issues identified through engagement with Aboriginal communities, and consultation with landowners, regulatory authorities, stakeholders and the general public, as well as through literature reviews, field studies and the professional experience of the assessment team, are consistent with other projects of this nature. Most of the associated potential effects on environmental indicators arising from construction of the Project can be readily mitigated by standard environmental mitigation measures common to pipeline projects in similar settings.

Project design and industry and regulatory standards anticipate and address many of the Project's potential residual effects on the environment. Routing of the proposed pipeline corridor to parallel existing linear disturbances for most of its length (89%) has reduced the potential effects associated with construction and operation of the Project. Mitigation measures have been developed to further reduce the severity of potential adverse residual environmental effects. Implementation of the proposed mitigation measures will further reduce the adverse residual environmental effects associated with the construction and operation of the Project. Applicable proposed construction mitigation measures will form the basis of operation and maintenance procedures during the life of the Project.

GLOSSARY

Aboriginal Traditional Knowledge (ATK)	Knowledge that is held by, and unique to, Aboriginal peoples.
active	Referring to a geological process which is currently or recently occurring.
adverse effect	The impairment of or damage to the environment or the health of humans, or damage to property or loss of reasonable enjoyment of life or property.
Agricultural Land Reserve	Administered by the Agricultural Land Commission, the Agricultural Land Reserve is a provincial zone in which agriculture is recognized as the priority use and non-agricultural uses are controlled.
air quality	A measure of the chemical pollutant loading in the atmosphere. As a measure or metric, it is generally related to human health endpoints, odour thresholds or environmental effects that are developed and regulated by municipal, provincial or federal governments. Ambient air quality objectives or standards have been developed to reflect the more stringent effect and measured or predicted levels are commonly compared to these values as a gauge of compliance as well as the degree of quality of the air.
alluvial fan	A fan shape formed from the deposition of fluvial materials as a stream or river decreases in velocity.
anthropogenic	Materials modified by human activities so that the original properties of the material have been altered.
appropriate regulatory authority	The regulator(s) that will be consulted prior to and during construction regarding approvals, notifications, constraints and the direction of activities.
automated mainline block valves	Enable remotely operated automatic emergency shut-down and isolation of the pipeline along a given segment.
avoidance	A means to prevent a potential adverse effect through routing/siting of the project, changes to project design or construction timing.
bedrock	Underlying rock beneath surficial sediments, or the exposed rock at surface.
blanket	Where surficial material thickness is generally sufficient to mask underlying topography.
channel	A watercourse with defined bed and banks. Includes rivulets streams, creeks and rivers.
clast	Fragments of pre-existing mineral or rock which are broken off by physical weathering and can form clastic rocks.
colluvium	Unconsolidated material created and/or deposited during gravity-induced processes.
compensation	A means intended to compensate unavoidable and potentially significant or unacceptable effects and may consist of offsets (no net loss), research, education programs, and financial compensation (considered only when all other options have been exhausted).
construction right-of-way	Right-of-way area comprised of temporary workspace and the permanent easement that is disturbed during construction. Consists of four newly constructed 914 mm OD (NPS 36) pipeline segments from: Edmonton to Hinton, Alberta; Hargreaves to Darfield, BC; Black Pines to Hope, BC; Hope to Burnaby, BC; and one newly constructed pipeline segment containing two 762 mm OD (NPS 30) pipelines from Burnaby to the Westridge Marine Terminal.
cultivated land	Agricultural land use where the ground is usually tilled or disturbed regularly.
cumulative effects	Changes to the environment that are caused by an action in combination with other past, present and future human actions (‘action’ includes projects and activities).
delta	A triangular tract of sediment deposited at the mouth of a river.
demersal	At the bottom of a body of water (in contrast to pelagic).

GLOSSARY Cont'd

drainage/catchment area	The geographical area of a watershed drained by a river and its tributaries to a point along a watercourse or water body.
element	A technical discipline or discrete component of the biophysical or human environment identified in the NEB *Filing Manual.*
Environmental Alignment Sheets	A series of maps noting the locations of select environmental features that are encountered by the proposed pipeline corridor, associated potential issues and recommended mitigation measures.
eolian	Relating to the action of the wind.
erosion	The removal of soil and rock material from a stream bank or surface by the action of water or wind movement.
feasible	Capable of being reasonably accomplished or brought about, given environmental and economic consideration.
fluvial	Pertaining to the overland flow of water in streams or rivers, or the sediments deposited by such flow.
foothills	Gradual increases in elevation at the base of a mountain range, transition between plains and mountains.
Footprint	The area directly disturbed by surveying, construction, and clean-up and operation of the pipeline and associated physical works and activities (including, where appropriate, the permanent rights-of-way, pump stations, tanks, Westridge Marine Terminal, temporary construction workspace, temporary stockpile sites, temporary staging sites, construction camps, access roads and power lines).
foreshore	Riparian habitat along the shore, above the mean highest high water level.
freshet	Marks an increase in stream runoff as a result of snowmelt or combined rainfall and snowmelt runoff.
glaciofluvial	Pertaining to streams fed by glacial meltwater, or the deposits and landforms produced by such streams.
glaciolacustrine	Pertaining to lakes at the margins of glaciers, or the sediments and processes involving such lakes.
glaciomarine	Areas of glacier ice in close proximity to marine environments, or glacial sediment deposited from suspension or gravity processes into such environments.
hay land	Agricultural land use which is seeded with perennial, usually non-native grasses and forbs, and which is typically cut and baled regularly.
headwater	A tributary stream forming part of a river's source.
horizontal directional drill	A trenchless crossing method allowing for guided installation of a pipeline along a prescribed bore path by using a surface-launched drilling rig having minimal impact on the surrounding area. Commonly used for watercourse or dense infrastructure crossing.
hydrostatic testing	The use of water for pressure testing a pipeline to a pressure of at least 25% greater than the planned operating pressure in order to confirm integrity of the pipeline.
inactive	Referring to a geological process which is not currently or recently occurring.
Indian Reserve	A tract of land, the legal title to which is vested in Her Majesty, that has been set apart by Her Majesty for the use and benefit of a band.
indicator	A biophysical, social or economic property or variable that society considers to be important and is assessed to predict Project-related changes and focus the effects assessment on key issues. One or more indicators (often referred to as Valued Ecosystem or Valued Socio-economic Components) are selected to describe the present and predicted future condition of an element. Societal views are understood by the assessment team through published information such as management plans and engagement with regulatory authorities, the public, Aboriginal communities, and other interested groups.

GLOSSARY Cont'd

integrity dig	Excavations conducted to visually inspect sections of pipe and repair defects, if present.
International Area	The area extending beyond Canada.
intertidal	Marine habitat between the mean lowest low water level and the mean highest high water level.
isolated crossing	A trenched watercourse crossing method whereby the flow is diverted around or over the trench.
Kinder Morgan Canada Inc.	Kinder Morgan Canada Inc. (KMC) is a corporation owned by Kinder Morgan Energy Partners. KMC operates Trans Mountain Pipeline L.P., a general partner of Trans Mountain Pipeline ULC (Trans Mountain).
lacustrine	Pertaining to a low energy water body such as a lake, or the sediments deposited from settling and gravity processes into this environment.
lentic	Static or standing, non-flowing waters such as lakes, ponds and reservoirs.
loam	A fertile clay and sand based soil containing humus.
Local Study Area	The zone of influence or area where the element and associated indicators are most likely to be affected by Project construction and operation. This generally represents a buffer from the centre of the proposed pipeline corridor or edge of the facility.
lotic	A flowing body of fresh water, such as a river or stream.
Lower Mainland Developed Area	Urban and agricultural area in the Fraser Valley including the City of Chilliwack, City of Abbotsford, Township of Langley, City of Surrey, City of Coquitlam and City of Burnaby.
matrix	The finer grained mass of material within a rock containing larger grains, crystals or clasts.
measurement endpoint	One or more 'measurement endpoints' are identified for each indicator to allow quantitative or qualitative measurement of potential Project effects. The degree of change in these measurable parameters is used to characterize and evaluate the magnitude of Project-related environmental and socio-economic effects. A selection of the measurement endpoints may also be the focus of monitoring and follow-up programs, where applicable.
merchantable timber	Timber that will be sold to a timber processor.
mitigation measure	Mean measures for the elimination, reduction or control of a project's adverse environmental effects, including restitution for any damage to the environment caused by such effects through replacement, restoration, compensation or any other means, or a means of reducing or managing a project's adverse socio-economic effects.
moraine	A mass of sediment deposited at the margins of or beneath a glacier.
National Area	The area extending beyond Alberta and BC but confined to Canada.
National Energy Board	An independent federal agency established in 1959 by the Parliament of Canada to regulate international and interprovincial pipelines and associated facilities.
native grassland	Lands dominated by native grasses and forbs, generally exhibiting a high species diversity, abundant grass thatch and little evidence of regular ground disturbance.
nearshore	Area of water extending 10 m seaward of the low-water tide mark.
non-salvageable timber	Timber and woody debris that will not be used during and after pipeline construction that is deposed of.
Noxious weeds	A plant designated in accordance with the regulations as a Noxious weed and includes the plant's seeds. A person shall control a Noxious weed that is on land the person owns or occupies (*Weed Control Act*).
offshore	Area of water extending from continental shelf to the nearshore boundary.
open cut crossing	A trenched watercourse crossing method typically conducted when a watercourse is dry or frozen to bottom.

GLOSSARY Cont'd

organic	Sediments resulting from the accumulation, decomposition, and compaction of organic material.
overburden	All rock or soil above the bedrock horizon in a given area.
peat	A brown, soil-like material made partly of organics and characteristic of boggy, acidic ground.
pelagic	Open water (*i.e.,* near the surface or in the water column but not at the bottom of a body of water [in contrast to demersal]).
physiographic region	Division of land based on the overall characteristics of the geological structures and topography.
plain	A flat or very gently sloping surface with relief generally less than 1 m.
plateau	An area of high land, generally having relatively flat terrain.
Port Metro Vancouver	A non-shareholder, financially self-sufficient corporation established by the Government of Canada, and accountable to the federal Minister of Transport, responsible for the operation and development of the assets and jurisdictions of over 600 km of shoreline, extending from Point Roberts at the Canada/US border through Burrard Inlet to Port Moody and Indian Arm, and from the mouth of the Fraser River, eastward to the Fraser Valley.
post-construction monitoring	A type of monitoring program that may be used to verify that mitigation measures effectively mitigated the predicted adverse environmental effects.
practical	Capable of or suitable to being put into effect, given environmental and economic consideration.
Prohibited Noxious weeds	A plant designated in accordance with the regulations as a Prohibited Noxious weed and includes the plant's seeds. A person shall destroy a Prohibited Noxious weed that is on land the person owns or occupies (*Weed Control Act*).
proposed pipeline corridor	Generally a 150 m wide corridor encompassing the pipeline construction right-of-way and temporary workspace.
Provincial Area	The area extending beyond regional or administrative boundaries, but confined to Alberta and BC.
Reclamation	The process of establishing a recovery trajectory to allow the land to re-establish its former or other productive use. The land will have the ability to support the land use that existed prior to the disturbance, but may support a different land use depending on the land management goals following the disturbance. Soils will be managed at contaminated sites to facilitate vegetation cover re-establishment suited to the post-disturbance land use. Reclamation will be considered complete once landscape, soils and vegetation goals for reclamation have been achieved.
Reference Kilometres	Distances measured along the general centre of the proposed pipeline corridor, referred to as Reference Kilometres (RKs), measured approximately 1 km apart.
Regional Study Area	The area extending beyond the Local Study Area boundary where the direct and indirect influence of other activities could overlap with project-specific effects and cause cumulative effects on the environmental or socio-economic indicator. This varies for each element.
relict	A process or landform which was formed conditions different from the present.
relief	The vertical height of land between the lowest point and highest point in the landscape.
residual effects	Effects that are present after mitigation is applied.
right-of-way	A legally defined strip of land with defined boundaries in which the pipeline runs through properties owned by others.
rolling	Topographic expression characterized by elongated hills with slope angles generally between 3-15°m.

GLOSSARY Cont'd

root zone material	Organic matter rich surface soil found within shrub, treed or forested land uses.
salvageable timber	Merchantable timber without a market or non-merchantable timber salvaged for use during and after pipeline construction.
scour	The removal of material from a channel by the erosive action of water resulting in channel widening or channel bed lowering.
shoo-flies	Vehicle and equipment access to the construction right-of-way from each side of a watercourse crossing where vehicle and equipment crossing of the watercourse on the right-of-way is not practical.
significant contribution to a cumulative environmental effect	A high probability of occurrence of a permanent or long-term cumulative effect of high magnitude that cannot be technically or economically mitigated.
significant residual environmental effect	A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.
silt	Fine material particles ranging in size from 0.002-0.05 mm in diameter.
subtidal	Marine habitat below the mean lower low water level.
supplemental (ongoing) studies	Studies to be conducted post submission of the application to confirm the effects assessment conclusions and gather site-specific information for the implementation of mitigation from the Project-specific environmental protection plans.
surficial geology	The geology of materials at or near ground surface including soils and bedrock.
tame pasture	Agricultural land use which is dominated by perennial, non-native grasses and forbs, which is used primarily for livestock grazing.
terrace	A step-like landform that comprises a horizontal surface and a scarp face, typically bordering a shoreline or river floodplain.
till	Unsorted material deposited directly by glacial ice showing no stratification.
topsoil	Organic matter rich surface soil developed within a grassland land use.
Traditional Ecological Knowledge (TEK)	A subset of ATK that is primarily concerned with the environment.
traditional land use (TLU) / traditional land and resource use (TLRU) / traditional marine resource use (TMRU)	Current and former use of the land/water and its resources by Aboriginal peoples.
tributary	A river or stream flowing into a larger river or water body.
turbidity	A measure of the lack of clarity or transparency of water caused by biotic and abiotic suspended or dissolved substances and is measured in nephelometric turbidity units (NTUs).
unconsolidated	Non-lithified sediment that has no mineral cement or matrix binding its grains.
undulating	Topography comprising gently sloping hillocks and hollows with slopes angles generally less than 15°m.
veneer	Where surficial material thickness is sufficient to mimic underlying topography but not mask it completely.
warranted	Justify or necessitate a course of action.
Westridge Marine Terminal	Trans Mountain-owned marine loading facility located within Port Metro Vancouver that can accommodate ships up to 120,000 deadweight tonnes and barges. This facility also receives jet fuel, which is delivered to Vancouver International Airport through Trans Mountain's affiliate, Trans Mountain (Jet Fuel) Inc. The Westridge Marine Terminal has been in operation since 1957.
wetland	*"land that is saturated with water long enough to promote wetland or aquatic processes as indicated by poorly drained soils, hydrophytic vegetation and various kinds of biological activity which are adapted to a wet environment."* (National Wetland Working Group 1997).

1.0 INTRODUCTION

1.1 Overview of the Project

Trans Mountain Pipeline ULC (Trans Mountain) is a Canadian corporation with its head office located in Calgary, Alberta. Trans Mountain is a general partner of Trans Mountain Pipeline L.P., which is operated by Kinder Morgan Canada Inc. (KMC), and is fully owned by Kinder Morgan Energy Partners, L.P. Trans Mountain is the holder of the National Energy Board (NEB) certificates for the Trans Mountain pipeline system (TMPL system).

The TMPL system commenced operations 60 years ago and now transports a range of crude oil and petroleum products from Western Canada to locations in central and southwestern British Columbia (BC), Washington State and offshore. The TMPL system currently supplies much of the crude oil and refined products used in BC. The TMPL system is operated and maintained by staff located at Trans Mountain's regional and local offices in Alberta (Edmonton, Edson, and Jasper) and BC (Clearwater, Kamloops, Hope, Abbotsford, and Burnaby).

The TMPL system has an operating capacity of approximately 47,690 m^3/d (300,000 bbl/d) using 23 active pump stations and 40 petroleum storage tanks. The expansion will increase the capacity to 141,500 m^3/d (890,000 bbl/d).

The proposed expansion will comprise the following:

- Pipeline segments that complete a twinning (or "looping") of the pipeline in Alberta and BC with about 987 km of new buried pipeline.
- New and modified facilities, including pump stations and tanks.
- Three new berths at the Westridge Marine Terminal in Burnaby, BC, each capable of handling Aframax class vessels.

The expansion has been developed in response to requests for service from Western Canadian oil producers and West Coast refiners for increased pipeline capacity in support of growing oil production and access to growing West Coast and offshore markets. NEB decision RH-001-2012 reinforces market support for the expansion and provides Trans Mountain the necessary economic conditions to proceed with design, consultation, and regulatory applications.

Application is being made pursuant to Section 52 of the *National Energy Board Act* (*NEB Act*) for the proposed Trans Mountain Expansion Project (referred to as "TMEP" or "the Project"). The NEB will undertake a detailed review and hold a Public Hearing to determine if it is in the public interest to recommend a Certificate of Public Convenience and Necessity (CPCN) for construction and operation of the Project. Subject to the outcome of the NEB Hearing process, Trans Mountain plans to begin construction in 2016 and go into service in 2017.

Trans Mountain has embarked on an extensive program to engage Aboriginal communities and to consult with landowners, government agencies (*e.g.*, regulators and municipalities), stakeholders, and the general public. Information on the Project is also available at www.transmountain.com.

The scope of the Project will involve:

- using existing active 610 mm (NPS 24) and 762 mm (NPS 30) OD buried pipeline segments;
- constructing three new 914 mm (NPS 36) OD buried pipeline segments totalling approximately 987 km:
  - Edmonton to Hinton – 339.4 km
  - Hargreaves to Darfield – 279.4 km
  - Black Pines to Burnaby – 367.9 km;

- reactivating two 610 mm (NPS 24) OD buried pipeline segments that have been maintained in a deactivated state:
    - Hinton to Hargreaves – 150 km
    - Darfield to Black Pines – 43 km;
- constructing two, 3.6 km long 762 mm (NPS 30) OD buried delivery lines from Burnaby Terminal to Westridge Marine Terminal (the Westridge delivery lines);
- installing 23 new sending or receiving traps (16 on the Edmonton-Burnaby mainlines), for in-line inspection tools, at nine existing sites and one new site;
- adding 35 new pumping units at 12 locations (i.e., 11 existing and one new pump station site);
- reactivating the existing Niton Pump Station that has been maintained in a deactivated state;
- constructing 20 new tanks located at the Edmonton (5), Sumas (1) and Burnaby (14) Terminals, preceded by demolition of 2 existing tanks at Edmonton (1) and Burnaby (1), for a net total of 18 tanks to be added to the system; and
- constructing one new dock complex, with a total of three Aframax-capable berths, as well as a utility dock (for tugs, boom deployment vessels, and emergency response vessels and equipment) at Westridge Marine Terminal, followed by the deactivation and demolition of the existing berth.

Figure 1.1 provides an overview of the location of the Project.

1.2 Purpose of the Environmental Assessment

As described in Section 3.0 of Volume 2, the Project will require a NEB CPCN pursuant to Section 52 of the *NEB Act* because the proposed pipeline crosses a provincial border and is greater than 40 km in length. In addition, according to the *Regulations Designating Physical Activities,* the Project is a designated project under the *Canadian Environmental Assessment Act, 2012* (*CEA Act, 2012*) because the new pipeline has a length greater than 40 km. The Environmental and Socio-economic Assessment (ESA) prepared for the Project considers the mandatory factors listed in Section 19(1) of the *CEA Act, 2012*, the factors listed in the NEB *Filing Manual* (NEB 2013a), and pertinent issues and concerns identified through consultation and engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public.

Trans Mountain understands that the NEB will conduct the review of the TMEP under the *NEB Act* as well as the *CEA Act, 2012.*

The Project is federally regulated and subject to obtaining a CPCN from the NEB and complying with the terms and conditions imposed by the NEB. Trans Mountain intends to work with Provincial regulatory authorities, municipal authorities and other agencies to provide them the information they need to fulfill their permitting requirements if the NEB approves the Project. Examples of these authorizations are listed in Section 1.5 of Volume 2.

1.2.1 Scope of the Project

According to the NEB *Filing Manual*, the scope of the Project includes the activities and components required to carry out the Project and allow it to proceed. This combination of activities for pipelines and facilities is provided in Section 1.1.

There will be additional marine traffic to move the product from the Project. Although regulation and authorization of marine transportation is not specifically within the jurisdiction of the NEB, the environmental and socio-economic effects of the increased marine traffic is considered by Trans Mountain in accordance with the NEB's direction from their *List of Issues* for the Project, released on July 29, 2013 (NEB 2013b). The predicted increase in marine traffic related to the Project is discussed in Volume 8A, Marine Transportation. Volume 8A addresses the requirements of the NEB's *List of Issues* (July 29, 2013) (NEB 2013b) as they relate to increased marine shipping resulting from the Project, the *CEA Act, 2012* and the NEB's *Filing Requirements Related to the Potential Environmental and Socio-Economic Effects of Increased Marine Shipping Activities, Trans Mountain Expansion Project* (September 10, 2013) (NEB 2013c).

The potential effects of an operational pipeline or marine spill are evaluated in Volumes 7 and 8A, respectively, including the risk of a spill, spill response plans, and the potential effects of hypothetical spill scenarios. The evaluation of the hypothetical spill scenarios also includes a Human Health Risk Assessment (HHRA) and Ecological Risk Assessment (ERA).

1.2.2 Scope of the Assessment

Scoping is the process of identifying the physical works and activities to include within the ESA, and the biophysical and socio-economic elements are likely to be affected by the Project. Proper scoping reduces the risk of including unimportant or irrelevant information in the assessment or excluding factors that should be assessed (NEB 2013a).

The NEB's *List of Issues* (July 29, 2013) for the Project (NEB 2013b) is provided below. Issues 4 and 5 of this list specifically informed the ESA.

1. *The need for the proposed project.*
2. *The economic feasibility of the proposed project.*
3. *The potential commercial impacts of the proposed project.*

4. *The potential environmental and socio-economic effects of the proposed project, including any cumulative environmental effects that are likely to result from the project, including those required to be considered by the NEB's Filing Manual.*
5. *The potential environmental and socio-economic effects of marine shipping activities that would result from the proposed project, including the potential effects of accidents or malfunctions that may occur (addressed in Volume 8A).*
6. *The appropriateness of the general route and land requirements for the proposed project.*
7. *The suitability of the design of the proposed project.*
8. *The terms and conditions to be included in any approval the Board may issue.*
9. *Potential impacts of the project on Aboriginal interests.*
10. *Potential impacts of the project on landowners and land use.*
11. *Contingency planning for spills, accidents or malfunctions, during construction and operation of the project.*
12. *Safety and security during construction of the proposed project and operation of the project, including emergency response planning and third-party damage prevention.*

The Board does not intend to consider the environmental and socio-economic effects associated with upstream activities, the development of oil sands, or the downstream use of the oil transported by the pipeline.

Recognizing the scope of the assessment described above, Trans Mountain must submit an ESA for the proposed pipeline and facilities. Trans Mountain's ESA includes a description of the following:

- the environmental and socio-economic setting;
- the predicted beneficial and adverse effects of the proposed Project on the socio-economic and biophysical environment over the life of the Project;
- the methods used for effects analysis, and the rationale for selecting the methods chosen;
- the proposed inspection, monitoring and mitigation measures; and
- the predicted significance of residual Project effects and residual cumulative effects.

The biophysical assessment (note that terms biophysical and environmental are frequently used interchangeably in the ESA) considers the mandatory factors listed in Section 19(1) of the *CEA Act, 2012,* the factors listed in the NEB *Filing Manual* (NEB 2013a), and pertinent issues and concerns identified through Aboriginal engagement and consultation with landowners, regulatory authorities, stakeholders, and the general public. It should be noted that Aboriginal engagement and stakeholder consultation does not end with the filing of the application to the NEB. Engagement, consultation as well as refinement of the environmental and socio-economic mitigation measures, continue through the next phases of the regulatory process and project execution.

The biophysical assessment considers the potential effects of the Project on the environmental conditions within defined spatial and temporal boundaries. These boundaries will vary with the issues and biophysical elements or interactions to be considered, and will reflect:

- the biophysical baseline setting within the spatial boundaries of the Project;
- the construction, operation, maintenance and decommissioning and abandonment phases of the proposed physical works and physical activities;
- the time required for an effect to become evident;

- the time required for a population to recover from an effect and return to a pre-effect condition;
- the area directly affected by proposed physical works and physical activities; and
- the area in which a population functions and within which a Project effect may be felt.

The spatial boundaries consider one or more of the following areas, as summarized below and described in detail in Section 7.2. Figures showing the spatial boundaries used for each element are provided in Sections 5.0, 6.0 and 7.0 depending on the element in question.

- A **Footprint Study Area (Footprint)** consisting of the area directly disturbed by surveying, construction and clean-up of the pipeline and associated physical works and activities (including, where appropriate, the permanent right-of-way, pump stations, tanks, Westridge Marine Terminal, temporary construction workspace, temporary stockpile sites, temporary staging facilities, construction camps, access roads, power lines, etc).
- A **Local Study Area (LSA)** consisting of the zone of influence or area where the element and associated indicators are most likely to be affected by Project construction and operation. This generally represents a buffer from the centre of the proposed pipeline corridor. Detailed discussions regarding the element-specific LSAs and associated rationale are provided in Section 7.2.
- A **Regional Study Area (RSA)** consisting of the area extending beyond the LSA boundary where the direct and indirect influence of other activities could overlap with project-specific effects and cause cumulative effects on the indicator. For each element considered, a separate spatial RSA boundary was established in consideration of the regional effects of the Project on the individual element. Further rationale for the establishment of the RSAs is provided in Section 7.2.
- A **Provincial Area** that extends beyond regional or administrative boundaries, but is confined to Alberta and BC.
- A **National Area** that extends beyond Alberta and BC but is confined to Canada.
- An **International Area** that extends beyond Canada.

Individually established ecological boundaries are described within the discussions in Section 7.2 for each applicable biological element. Spatial ecological boundaries were determined by the distribution, movement patterns and potential zones of interaction between an element and the Project. The ecological boundary may be limited to the Footprint or extend beyond the physical boundaries of the area of the Project component since the distribution or movement of an element can be local, regional, provincial, national or international in extent.

Reconnaissance, detailed field studies and desktop studies considered a proposed pipeline corridor approximately 150 m wide, encompassing the pipeline construction right-of-way, temporary workspace, pump stations, and related facilities. In the event that an area of interest was identified, field crews expanded their survey as appropriate (the survey was not expanded to an area greater than the LSA) to identify the extent and distribution of the area of interest, and to ensure that a comprehensive assessment of the feature(s) were being surveyed.

The time frames of the biophysical assessment of the Project include the planning, construction (including reactivation/modification), operation, and decommissioning and abandonment phases. Pending regulatory approval, construction activities are expected to commence in Q1 2016 and extend to Q4 2017. The operation phase commences following completion of construction in Q4 2017 and extends for the useful life of the pipeline (approximately 50-70 years).

The biophysical assessment also considers residual and cumulative effects that are likely to result from the Project in combination with existing activities and reasonably foreseeable developments that have been or will be carried out. In areas where environmental field crews were not able to get access for resource surveys, desktop studies, literature reviews, information derived from study of adjacent lands and professional judgment were relied on to make predictions. Possible effects and available mitigation measures are well known and can be relied on to make assessment predictions. Where necessary to confirm impact predictions and gather site-specific information, Trans Mountain will be conducting additional studies on those areas where access was not available. Where warranted, follow-up studies may be recommended.

1.3 Overview of Volume 5A

The biophysical component of the ESA for the Project has been prepared under the guidance provided by the NEB *Filing Manual* and the requirements of the *CEA Act, 2012*. In addition, the mitigation measures, contingency and management plans provided in the project-specific Environmental Protection Plans (EPPs) for the pipeline, facilities and Westridge Marine Terminal (Volumes 6B, 6C and 6D), and information on the Environmental Alignment Sheets (Volume 6E) will form the foundation for future environmental management activities by Trans Mountain, particularly during the construction phase of the Project. The socio-economic component of the ESA for the Project is provided in Volume 5B. The environmental and socio-economic effects of increased Project-related marine vessel traffic are discussed in Volume 8A. Volume 5A is divided into the following sections.

1.0 **Introduction:** Provides the purpose of the environmental assessment, a description of the scope of the Project and the scope of the environmental assessment, an outline of Volume 5A and a summary of the Project team.

2.0 **Project Description:** Provides a description of the Project components and Project phases related to the pipeline and facilities component of the Project.

3.0 **Public Consultation, Aboriginal Engagement and Landowner Relations:** Provides a summary of public involvement and Aboriginal engagement activities conducted in preparation of the ESA for the pipeline and facilities component of the Project. This section discusses the engagement with Aboriginal communities and consultation with landowners, federal, provincial and municipal regulatory authorities, and other interested parties such as environmental non-government organizations (ENGOs), where applicable. The section also identifies key environmental issues raised during the consultation and engagement program. The consultation conducted in the preparation of this volume was designed to complement the Trans Mountain public consultation and Aboriginal engagement programs which is discussed in Volumes 3A, 3B and 3C.

4.0 **Corridor and Facility Site Selection:** Provides a detailed description of the proposed pipeline corridor selection processes and site selection process for pipeline facilities, pump stations and storage tanks.

5.0 **Environmental Setting for the Pipeline:** Provides a description of the current environmental conditions present along the proposed pipeline corridor and reactivated pipeline segments.

6.0 **Environmental Setting for Facilities:** Provides a description of the current environmental conditions present at pump stations, storage tank sites, the Westridge Marine Terminal and temporary facilities.

7.0 **Environmental Effects Assessment:** Describes the effects assessment and identifies the potential environmental effects, mitigation measures and potential residual effects, including an assessment of their significance for the following Project components: pipeline; temporary facilities; pump stations (including power lines); storage tanks; Westridge Marine Terminal; and reactivated pipeline segments.

8.0 **Cumulative Effects Assessment:** Provides a description of the Project's contribution to potential adverse cumulative effects as well as an assessment of their significance.

9.0 **Supplemental Studies:** Provides a description of the plans to carry out ongoing studies.

10.0 **Follow-up:** Provides a description of any proposed follow-up programs.

11.0 **Conclusion:** Provides conclusions related to the significance of potential adverse residual effects and cumulative effects associated with the pipeline and facilities components of the Project.

1.4 Project Team

The companies that assisted with the preparation of Volume 5A are listed in Table 1.4-1.

TABLE 1.4-1

PROJECT TEAM

Supporting biophysical technical reports are provided in Volume 5C. The technical reports provide discipline-specific background information, the methodology and results of field surveys and research conducted in support of the biophysical assessment. These technical reports and previous surveys and studies provide an information base for the pipeline and facilities component of the Project. The authors of the supporting technical reports also participated in the identification of potential effects, the evaluation of significance of residual effects and the development of mitigation measures within their respective disciplines.

2.0 PROJECT DESCRIPTION

This section provides a description of the Project's components and summarizes activities associated with the construction, operation, and decommissioning and abandonment phases of the pipeline and associated facilities.

2.1 Project Components

The following subsections describe the components of the Project and locations of the proposed and reactivated pipeline segments, proposed activities at pump stations, temporary facilities, proposed storage tank facilities, and the expansion of the Westridge Marine Terminal. More detailed descriptions are provided in Volume 2. The existing TMPL system and proposed and reactivated segments, as well as pump stations and terminals, are shown in Figure 1.1-1 of Section 1.0.

To delineate features along the proposed pipeline corridor, Reference Kilometre (RK) posts approximately 1 km apart have been established based on the general centre of the proposed pipeline corridor. RK 0.0 is located at the Edmonton Terminal where the existing TMPL system starts. The end of the existing TMPL system is located at the Burnaby Terminal (RK 1179.8), where two approximately 3.6 km long (RK 0 to RK 3.6) delivery lines extend from the Burnaby Terminal to the Westridge Marine Terminal.

The ESA is based on preliminary engineering and designs. In general, conservative assumptions have been used. However, further technical development during the upcoming phases of engineering and detailed design in 2014 and 2015 will confirm the current assessment of environmental effects. If there are substantive changes from the preliminary designs, additional assessment and regulatory consultation may be required.

2.1.1 Pipeline

2.1.1.1 New Pipeline

For the purposes of the environmental assessment, the proposed pipeline is divided into five distinct segments:

- The Edmonton to Hinton Segment extends from the existing Edmonton Terminal at SW 5-53-23 W4M (RK 0.0) and ties-in to the existing TMPL system at the Hinton Pump Station at NW 33-49-26 W5M (RK 339.4). The total length of the Edmonton to Hinton Segment is 339.4 km.
- The Hargreaves to Darfield Segment extends from the existing TMPL system at 20-B / 083-E-3 (RK 489.6) and ties-in to the existing TMPL system at the Darfield Pump Station at 75-B / 092-P-8 (RK 769.0). The total length of the Hargreaves to Darfield Segment is 279.4 km.
- The Black Pines to Hope Segment extends from the existing TMPL system at 41-K / 092-I-16 (RK 811.8) and ties-in to the proposed pipeline at the Hope Pump Station at 44-E / 092-H-6 (RK 1043.7). The total length of the Black Pines to Hope Segment is 231.9 km.
- The Hope to Burnaby Segment extends from the proposed pipeline at the Hope Pump Station at 44-E / 092-H-6 (RK 1043.7) and ties-in to the Burnaby Terminal at 25-D / 092-G-7 (RK 1179.8). The total length of the Hope to Burnaby Segment is 136.1 km.
- The Burnaby to Westridge Segment extends from the Burnaby Terminal at 25-D / 092-G-7 (RK 0.0) and ties-in to the Westridge Marine Terminal at 46-D / 092-G-7 (RK 3.6). The total length of the Burnaby to Westridge Segment is 3.6 km.

The proposed route of the new pipeline segments is identified along an approximately 150 m wide corridor. Although the proposed pipeline will generally require a construction right-of-way of 45 m, the corridor width varies along the route depending on the types of land use and potential engineering and environmental constraints.

The proposed pipeline corridor will parallel the existing TMPL system right-of-way to the greatest extent feasible considering, among other factors, present land uses and terrain adjacent to the existing TMPL system right-of-way. To reduce the area of new disturbance, the proposed pipeline corridor will parallel other existing linear disturbances where feasible. For the purposes of this ESA, existing linear disturbance include electrical transmission lines, oil and gas pipelines, fibre optic lines, railways, highways and permanent roads.

A summary of technical details for the proposed pipeline corridor is provided in Table 2.1-1. Technical details specific to reactivated segments are provided in the following subsection. An overview map of the existing TMPL system and the proposed pipeline corridor is provided in Section 1.0. Additional information pertaining to the alignment of the proposed pipeline corridor and the location and rationale of route deviations is provided in Section 4.0 and Volume 2.

TABLE 2.1-1

TECHNICAL DETAILS – PROPOSED PIPELINE CORRIDOR

Total Length (including Westridge delivery lines):	Approximately 990.5 km
Length Parallel to Existing TMPL:	661.6 km (66.8%)
Length Deviating from Existing TMPL:	328.9 km (33.2%)
Total Length Parallel to Other Existing Linear Features:	221.2 km (22.3%)
Total Length Deviating from Other Existing Linear Features:	107.8 km (10.9%)
Product:	Heavy synthetic crude oil and diluted bitumen (also capable of transporting light crude oil and light synthetic oil, if necessary)
Source Point:	Existing Edmonton Terminal at SW 5-53-23 W4M (RK 0.0)
Delivery Point:	Existing Sumas Terminal at a-097-B/092-G-01 (RK 1117.5), existing Burnaby Terminal at a-025-D/092-G-07 (RK 1179.8) and existing Westridge Marine Terminal at 46-D / 092-G-7 (RK 0.0 [Burnaby Terminal] to RK 3.6)
Pipe Size:	One 914.4 mm OD (NPS 36) pipeline from Edmonton Terminal to Burnaby Terminal and two 762 mm OD (NPS 30) Westridge delivery lines from Burnaby Terminal to Westridge Marine Terminal
Construction Footprint (typical) (construction right-of-way):	The construction right-of-way will typically be 45 m wide, including an approximately 18 m wide permanent easement. The remainder of the construction right-of-way width will be used as temporary workspace.
Construction Footprint (atypical) (construction right-of-way):	The construction right-of-way will be narrowed to 10 m or less where specific constraints or limitations are identified, such as parks and sensitive areas, confined valleys, urban areas, adjacent infrastructure or land features and when in proximity to the existing TMPL right-of-way.
Temporary Workspace:	Additional temporary workspace will be necessary at select locations to accommodate construction activities (*e.g.*, road, rail, buried utility line and water crossings, sharp sidebends, tie-ins, and locations where extra depth of cover, deep topsoil, three-lift handling or heavy grading is necessary). Trans Mountain will also acquire temporary workspace for Project construction needs such as stockpile sites, equipment storage sites, shoo-flies, contractor staging areas, borrow pits and construction work camps (refer to Section 2.1.2 for additional information).
Trench Depth	1.8-2.1 m, deeper at watercourses
Minimum Depth of Cover:	0.9 m (0.6 m in bedrock)
Typical Trench Width:	Approximately 2 m
Test Medium:	Water
New Above Ground Line Facilities:	Includes approximately 86 automated mainline block valves (MLBVs), scraper traps and a pressure control station (pending results of detailed hydraulic studies). Refer to Section 2.1.1.3 for a description of automated MLBVs and the pressure control station, and Sections 2.1.3 to 2.1.5 for information on scraper trap facilities at pump stations, storage terminals and the Westridge Marine Terminal, respectively.

2.1.1.2 Reactivated Pipeline Segments

The reactivated pipeline segments from Hinton to Hargreaves and Darfield to Black Pines generally parallel the existing TMPL right-of-way. The existing TMPL easement through Jasper National Park and Mount Robson Provincial Park is 6.1 m wide and 18 m wide, respectively. Outside the parks, the existing easement along the two segments is generally 18 m wide. Permanent surface disturbance along the reactivated segments will be limited to locations where automated MLBVs will be installed or where existing valves will be automated. Temporary surface disturbance will be limited to preparation for in-line inspection, defect repair and hydrostatic testing.

2.1.1.3 Pipeline Associated Permanent Facilities

Approximately 86 automated MLBVs will be installed along the pipeline for emergency shutdown and isolation of pipeline segments. Automated MLBVs will be constructed within the operating pipeline right-of-way and most will be sited adjacent to existing TMPL valves. Many automated MLBVs will be accessed by existing access roads, however, permanent access roads may be required at yet unspecified locations. Automated MLBVs will require a permanent power source. Typically, new power lines will only be used when there is a source nearby, thereby reducing any additional disturbance. Otherwise, alternative power sources such as solar panels, battery banks and/or nitrogen bottles will be used. Each automated MLBV installation will require a fenced and gravelled operating area of approximately 5 m x 12 m (60 m^2). The exact location of automated MLBVs and power sources utilized will be determined during the detailed engineering and design phase.

Pending results of detailed hydraulic studies, a pressure control station may be required for TMEP at the Hope Pump Station. The purpose of the station, if required, will be to control pressure in the pipeline to ensure product flows at a relatively steady rate as it leaves Kingsvale Pump Station (high elevation) and flows down slope toward the Lower Mainland (low elevation). The station will utilize the existing electrical distribution line and access road to the Hope Pump Station. No new lands will be required.

2.1.2 Pipeline Associated Temporary Facilities

Temporary Access Roads and Shoo-flies

Existing infrastructure will be used where practical for access during construction. Access to the new pipeline construction right-of-way, where it is not contiguous with the existing pipeline alignment, will be from existing public and private access points and roads (respecting traffic safety and concern for other users), controlled existing access, rights-of-way of others (*e.g.*, Canadian National Railway Company [CN], Telus, Spectra), and existing shoo-flies and trails. Only approved access will be used.

Where existing access is not sufficient or available, access might be improved along existing trails as necessary during construction by widening, re-grading or other means. Former access trails may also be reactivated and existing rights-of-way of others may be used to reduce disturbance.

Where new temporary access is required, all applicable authorizations and approvals will be sought on private and public lands, including parks and protected areas. Temporary access roads and shoo-flies will typically be 5 m wide to accommodate equipment and machinery.

Temporary Facility Sites

In addition to the pipeline easement and associated temporary workspace, land will be required for temporary sites, including:

- staging and stockpile sites;
- equipment storage sites;
- construction office sites;
- construction work camps (likely one in Alberta and two in BC);
- trenchless crossing work areas;
- borrow pits; and
- log decks.

Wherever practical, these temporary facilities will be located within previously disturbed areas to minimize overall Project disturbance. All temporary facility sites will be reviewed from an environmental perspective before their use.

Sewage and grey water will be treated in a temporary treatment facility on-site at each facility and hauled to regional facilities for disposal. Power will be supplied by generators and by the local electrical grid, where available.

If permitted, potable water at the facilities will be drawn from adjacent sources such as the Athabasca, Fraser, North Thompson, Coldwater and Coquihalla rivers, at rates acceptable to the appropriate regulatory authorities and filtered before use. Otherwise, potable water will be trucked in to each work camp site.

2.1.3 Pump Station Facilities

Pump stations are positioned along the existing TMPL system at 23 locations to maintain pressure and move the product along the line and monitor flow. To accommodate the expansion, the Project will include construction and operation of new pump stations serving the new pipeline at 10 of the existing pump station sites at Edmonton, Gainford, Wolf, Edson and Hinton in Alberta, and at Rearguard, Blue River, Blackpool, Kamloops and Kingsvale in BC. Two new pump stations will also be constructed and operated at a new greenfield site at Black Pines, BC to serve both the existing pipeline and new pipeline.

Pump stations are generally located within a fenced area on approximately 4 ha of land and contain the following: pumps and motors housed in a building; an electrical service building; an operator building; an electrical substation; and station piping and valves. Pump stations will be connected to the provincial power grid via new or existing power lines. Trans Mountain or a third party (*e.g.*, AltaLink Management Ltd., BC Hydro and Power Authority [BC Hydro]) will apply to the appropriate provincial regulatory authorities for electrical facilities necessary to connect with the provincial power lines. Existing access will be utilized for all pump stations with the exception of Black Pines, which will require construction of a permanent 5 m wide gravelled access road approximately 25 m in length, subject to final site selection and detailed engineering and design.

There will be one new 2,500 HP pumping unit installed on the NPS 24 pipeline heading south along the Puget Sound line from the Sumas Pump Station into Washington State. The existing Jasper Pump Station in Alberta will be relocated from the TMX Anchor Loop pipeline to serve TMPL system (currently deactivated). Valves, controls and other instruments will also be installed as part of the pump station modifications.

As an outcome of the TMEP, the Niton Pump Station will be reactivated (currently deactivated) to serve the existing pipeline and the existing pump stations at Wolf and Blue River will be deactivated since they will no longer be required for the existing TMPL system. The infrastructure that is currently in place at the deactivated pump stations will remain on-site should there be the need to reactivate either of the stations at some point in the future. The existing electrical service building and variable frequency drive building will, however, serve the new pump stations at Wolf and Blue River. The deactivated stations will be disconnected from the existing TMPL system and purged with nitrogen. All associated reactivation and deactivation activities will be conducted within the current fenced areas and no new disturbance will be required.

Although no changes to pumping capacity are anticipated at the Darfield Pump Station, valve modifications and installation of a new scraper trap (sending and receiving) are planned.

No work is planned at the following pump stations: Stony Plain and Chip, Alberta; and Albreda, Chappel, Finn, McMurphy, Stump, Hope, Wahleach and Port Kells, BC.

A summary of the location, components, present land use, land requirements and ancillary facilities (including scraper traps) at each pump station is provided in Table 2.1-2. Pump station schematics are provided in Volume 4A.

TABLE 2.1-2

TECHNICAL DETAILS – PUMP STATION ACTIVITIES

Pump Station and Location	Activities	Land Use and Land Requirements	Nearest Residence/Receptor from Facility Fence Line
Edmonton • RK 0.0 • SW 5-53-23 W4M	• new pump station[1] consisting of four electrically driven 5,000 HP pumps plus one spare[2] added to serve TMEP • new scraper facilities (sending) on TMEP • a new substation • a new power line (to be determined by provincial regulatory authority)[3] • fencing	industrial / within existing Trans Mountain-owned lands	• 1.9 km northwest and southeast
Gainford • RK 117.5 • NE 13-53-6 W5M	• new pump station[1] consisting of three electrically driven 5,000 HP pumps to serve TMEP • upgrades to existing substation • fencing	industrial and forested (clearing required) / within existing Trans Mountain-owned lands	• 140 m east
Niton • RK 191.4 • SW 34-53-13 W5M	• reactivate two existing 2,000 HP pumps to serve TMPL	industrial / within existing Trans Mountain-owned lands	• 1 km southwest
Wolf • RK 206.2 • NW 19-53-14 W5M	• new pump station[1] consisting of two electrically driven 5,000 HP pumps serving TMEP • existing pump building will be deactivated • fencing	industrial / within existing Trans Mountain-owned lands	• 600 m west-southwest
Edson • RK 247.1 • SW 18-53-18 W5M	• new pump station[1] consisting of three electrically driven 5,000 HP pumps serving TMEP • new scraper facilities (sending and receiving) on TMEP • replace existing substation • a new power line (to be determined by provincial regulatory authority)[3] • fencing and on-site gravel road	industrial / within existing Trans Mountain-owned lands	• 360 m west
Hinton • RK 339.4 • NW 33-49-26 W5M	• new pump station[1] consisting of three electrically driven 5,000 HP pumps serving TMEP • new scraper facilities (sending) on TMPL • fencing	industrial / will require acquisition of approximately 0.32 ha (35 m x 90 m) new land outside existing Trans Mountain-owned lands to the west	• 820 m southwest
Jasper • NW 2-46-1 W6M	• relocate two existing 2,500 HP pumps from the TMX Anchor Loop pipeline to TMPL (currently deactivated) • drag resistant agent injection facility requiring small storage tank (with secondary containment) and a high pressure injection pump	industrial / within Crown lands currently leased by Trans Mountain	• 1.3 km southeast
Rearguard • RK 498.3 • d-068-K/083-D-14	• new pump station[1] consisting of two electrically driven 5,000 HP pumps serving TMEP • remove scraper facilities (sending and receiving) from Hargreaves • new scraper facilities (sending and receiving) on TMPL and TMEP • fencing and on-site gravel road	industrial and disturbed forested (clearing required) / will require acquisition of approximately 0.7 ha (70 m x 100 m) new land outside existing Trans Mountain-owned lands to the east	• none within 2 km

TABLE 2.1-2 Cont'd

Pump Station and Location	Activities	Land Use and Land Requirements	Nearest Residence/Receptor from Facility Fence Line
Blue River • RK 614.7 • a-035-F/083-D-03	• new pump station[1] consisting of three electrically driven 5,000 HP pumps serving TMEP • existing pump building will be deactivated	industrial / within existing Trans Mountain-owned lands	• 30 m east and south
Blackpool • RK 736.8 • c-073-B/092-P-09	• new pump station[1] consisting of three electrically driven 5,000 HP pumps serving TMEP • upgrade existing transformer • fencing and on-site gravel road	industrial / within existing Trans Mountain-owned lands	• 150 m north-northwest
Darfield • RK 769 • d-075-B/092-P-08	• new scraper facilities (receiving) on TMEP • fencing	industrial and agricultural / will require acquisition of approximately 0.07 ha (23 m x 30 m) new land outside existing Trans Mountain-owned lands extending from the northwest corner of the property line	• 150 m south
Black Pines • RK 811.8 • d-041-K/092-I-16	• new pump station[1] consisting of two electrically driven 5,000 HP pumps serving TMEP • new pump station[1] consisting of two electrically driven 2,500 HP pumps serving TMPL • new substation to serve both lines • new scraper facilities (sending and receiving) on TMPL and TMEP • new access road approximately 5 m x 25 m[3] • new 138 kV power line approximately 50 m x 2.2 km[3] • fencing and on-site gravel road	forested (clearing required) / requires acquisition of approximately 150 m x 150 m (2.3 ha) of privately-owned land	• 600 m south
Kamloops • RK 850.8 • d-094-E/092-I-09	• new pump station[1] consisting of three electrically driven 5,000 HP pumps plus one spare[2] added to TMEP • new substation to serve TMEP • new scraper facilities (sending and receiving) on TMEP	industrial with grading required / within existing Trans Mountain-owned lands	• 520 m southeast
Kingsvale • RK 955.6 • b-023-L/092-H-15	• new pump station[1] consisting of two electrically driven 5,000 HP pumps serving TMEP • replace existing substation • new 138 kV power line approximately 50 m by 23.5 km[3] • fencing	forested (clearing and grading required) / within existing Trans Mountain-owned lands	• 300 m southwest
Sumas • RK 1113.8 • c-073-B/092-G-01	• one electrically driven 2,500 HP pump serving the Puget Sound line • upgrade existing substation	industrial / within existing Trans Mountain-owned lands	• 110 m southwest

Notes: 1 New pump stations require the installation of an electrical service building, pump building and operator building, as well as motors, instrumentation, station piping and valves. Existing electrical service buildings and operator buildings will be used where possible.

2 Spare pumps will remain inactive during normal operations.

3 Power line routing and the new access road will be confirmed during the detailed engineering and design phase.

2.1.4 Tank Facilities

To serve the expanded pipeline, a total of 20 new storage tanks will be constructed: 5 at the Edmonton Terminal; 1 at the Sumas Terminal; and 14 at the Burnaby Terminal. The new welded steel tanks will be similar in structure to the existing tanks at the terminals and installed on stable, engineered foundations within a bermed containment area.

After the site has been rough graded, foundations for each tank will be constructed. Foundation design parameters may vary across terminals based on the results of detailed geotechnical surveys. Leak-detection systems consisting of a passive-weeping channel between the liner and tank floor will be installed. An internal tank liner, covering the bottom and about 1 m up the shell, will be provided for corrosion prevention. Cathodic protection will be installed on all new tanks as an added measure to protect against corrosion. Tank control systems will include a radar gauging system for high and low level monitoring and overfill protection. Redundant instrumentation for overfill protection will be provided.

All tanks will have secondary containment consisting of compacted clay or a geo-synthetic liner. Secondary containment will be capable of containing 100% of the working volume of the largest tank plus 10% of the working volume of other tanks that share a common impoundment. The bermed area will be graded to direct all surface water to a runoff containment area, where it can be inspected before release. Surface runoff within these containment areas will be released through manually controlled valves following water quality monitoring. Drainage features will be designed and installed to ensure that no runoff originating off-site will be allowed to enter the proposed development area.

Additional components include valves, metering and provers, pumps and inter-connecting pipes. The existing fire-protection system and stormwater management system will be expanded to accommodate the additional tanks at each site. Final details will be determined during the detailed engineering and design phase.

A summary of technical details associated with the proposed storage tanks at the Edmonton, Sumas and Burnaby terminals is provided in Table 2.1-3. Terminal schematics are provided in Volume 4A.

TABLE 2.1-3

TECHNICAL DETAILS – STORAGE TANKS AND ASSOCIATED FACILITIES AT THE EDMONTON, SUMAS AND BURNABY TERMINALS

Technical Details	Edmonton Terminal	Sumas Terminal	Burnaby Terminal
Location	• RK 0 • SW 5-53-23 W4M	• RK 1117.5 • a-097-B/092-G-01	• RK 1179.8 • a-025-D/092-G-07
Nearest Residence/Receptor from Facility Fence Line	• 1.9 km northwest and southeast	• 60 m south	• approximately 50 m south
Product	diluted bitumen, synthetic bitumen, diluted synthetic bitumen, light crude and synthetic crude		
Existing Storage Tank Capacity	• 19 tanks with an approximate capacity of 429,270 m^3 (2.7 million bbl)[1]	• 6 storage tanks with an approximate capacity of 113,680 m^3 (715,000 bbl)	• 13 tanks with an approximate capacity of 270, 280 m^3 (1.7 million bbl)
New Storage Tank Capacity	• 2 x 34,980 m^3 (220,000 bbl) • 2 x 63,600 m^3 (400,000 bbl) • 1 x 11,920 m^3 (75,000 bbl)	• 1 x 27,820 m^3 (175,000 bbl)	• 2 x 39,750 m^3 (250,000 bbl) • 10 x 45,310 m^3 (285,000 bbl) • 2 x 53,260 m^3 (335,000 bbl)
Maximum Tank Height	21.3 m	17.1 m	18.3 m
Roof Type	external floating roof	fixed steel roof with internal floating roof	
Overall Site Area	47.2 ha	43.3 ha (only 11.6 ha currently disturbed)	76.7 ha
Total Containment Capacity	will allow for containment of 100% of the working volume of the largest tank plus 10% of the working volume of other tanks that share a common impoundment and stormwater		
Runoff Containment Area Size / Capacity	1-in-100-year storm event with a 24 hour duration period		
Pump Sizes	Seven 800 HP booster pumps (electric drive)	None	Eight 500 HP booster pumps (electric drive)
Test Water Source	from existing storage ponds filled with water diverted from nearby creeks (subject to existing or future permit approval conditions) and/or purchased from the municipal water supply		

TABLE 2.1-3 Cont'd

Technical Details	Edmonton Terminal	Sumas Terminal	Burnaby Terminal
Land Requirements	within existing Trans Mountain fence line on previously disturbed industrial lands	within the existing Trans Mountain property boundary, however, existing fence line will be moved approximately 20 m north (20 m x 350 m [0.7 ha] of new disturbance) to accommodate a new access road and earthworks for modifications to the tank secondary containment berm	within existing Trans Mountain fence line on previously disturbed industrial lands, however, disturbance to natural watercourses within the existing site boundaries will result in the loss of riparian vegetation as well as a change in natural surface flow patterns
Associated Infrastructure	on-site access roads to each new tank, power requirements/upgrades	on-site access road to the new tank, power requirements/upgrades are not required due to small increase in load at this facility	on-site access roads to each new tank and other associated facilities, power requirements/upgrades will be determined by BC Hydro (anticipated that approximately 5 MW of additional power will be required)
Other Activities	an existing 12,720 m^3 (80,000 bbl) tank will be dismantled and replaced by the new 11,920 m^3 (75,000 bbl) tank	to make space available for the new tank, a power line will be relocated approximately 20 m to the north and an existing containment berm will be dismantled and the area graded to support the foundation for the new tank. A new containment berm will be constructed before the new tank is put into operation	new scraper facilities for new pipeline (receiving) and Westridge delivery lines (sending), and an existing 12,720 m^3 (80,000 bbl) tank will be dismantled and replaced by one of the 45,310 m^3 (285,000 bbl) tanks

Note: 1 Trans Mountain is currently in the process of constructing the Edmonton Terminal Expansion Project, which involves constructing 10 new tanks and associated facilities at the Edmonton Terminal. This project was approved by the National Energy Board (NEB) in March 2008 and is now being constructed under Amending Order AO-005-XO-T246-04-2008. In February 2013, Trans Mountain applied to the NEB to vary Amending Order AO-005-XO-T246-04-2008 to permit construction of four additional tanks at the Edmonton Terminal for a total of 14 tanks. The NEB issued an Amending Order AO-006-XO-T246-04-2008 on June 20, 2013 and the four additional tanks are expected to come into service by late 2014. Furthermore, in July 2013 Trans Mountain applied to the NEB (File OF-Fac-Oil-T260-2013-04 01) to construct an additional two tanks at the Edmonton Terminal. Pending regulatory approval, the two tanks are expected to come into service by late 2014 or early 2015.

2.1.5 Westridge Marine Terminal

The Westridge Marine Terminal is located on the south shore of Burrard Inlet east of the Second Narrows at RK 3.6 (d-047-D/092-G-07) of the Westridge delivery lines. Preliminary design of the additional facilities at the Westridge Marine Terminal is currently underway. These plans include constructing the following dock facilities:

- one dock with three operational berths for Aframax tankers, with one of the three new berths equipped to accommodate oil and jet fuel barges; and
- one small utility dock with multiple berths for pilot launches, tugs, spill response vessels and equipment.

The proposed configuration of the new docks is provided in Volume 4A. Some near shore dredging might be necessary to accommodate construction of the new docks.

Each of the three tanker berths consists of a number of individual elements or structures arranged in accordance with accepted industry practice. Typical elements include:

- fender and mooring structures;
- vessel access towers;
- delivery and receipt pipeline systems, including loading arms;
- pedestrian catwalks connecting the dolphin structures to the central platform; and
- vapour recovery systems and fire-suppression systems.

The existing water lease will need to be expanded to accommodate the new docks. Foreshore lands will also be expanded along the lateral footprint to provide the necessary space for shore equipment and structures. The outer face of the fill will be protected with rip rap (stone armour) to prevent erosion.

New scraper receiving facilities will be installed for the two new Westridge delivery lines between the Burnaby Terminal and the Westridge Marine Terminal. The new scraper receiving facilities will be installed within the existing fence line of the Westridge Marine Terminal on previously disturbed lands owned by Trans Mountain.

The existing electrical substation and electricity supply line within the Westridge Marine Terminal will be upgraded as required. Electrical upgrades will be determined through a study to be conducted by BC Hydro. At this time, it is anticipated that an additional 3 MW of power will be required at this facility. No new roads will be required to access the terminal. However, an improved site access road and an expanded parking area for staff and contractors will be required. No new access will be constructed across the existing Canadian Pacific Rail line that bisects the facility.

The nearest residence is located approximately 75 m south of the Westridge Marine Terminal property boundaries.

2.2 Project Execution

This subsection describes the activities to be conducted as part of construction of the Project, including: construction of the new pipeline segments and associated permanent and temporary facilities; pipeline reactivation; pump station construction, expansion, reconfiguration, reactivation and deactivation; storage tank construction; and expansion of the Westridge Marine Terminal. It also describes the construction schedule and estimated workforce.

2.2.1 Construction Activities

Standard activities and equipment requirements for construction and other activities associated with the Project are described in Table 2.2-1. These activities are presented in their general order of occurrence. All of these activities are considered in the environmental effects assessment (see Section 7.0). For detailed descriptions of Project activities refer to Volume 4B.

TABLE 2.2-1

PROJECT ACTIVITIES

Construction Phase	Associated Activities
Engineering	All Project components will be designed and constructed in accordance with all applicable Canadian Standards Association (CSA) standards, the *National Energy Board Onshore Pipeline Regulations* (*NEB OPR*) and additional requirements described in Volume 4A.
New Pipeline Segments	
Construction Survey	Activities include line-of-sight clearing with chain saws (where needed), flagging and staking of the boundaries of the construction right-of-way and temporary workspace, as well as marking the trench line and existing utilities. Avoidance areas, such as protected habitats or rare plants, will also be appropriately fenced or flagged.
Clearing	Vegetation (trees, stumps, brush, grasses, crops and other vegetation) and snow will be cleared or mowed from the construction right-of-way and temporary workspace. Equipment used during clearing activities may include chainsaws, rotary grinders, feller-bunchers, hydro-axes or other tree-clearing and brushing equipment, as well as skidders, bulldozers and excavators. A stump mulcher will be utilized rather than grubbing on areas where topsoil or root zone material salvage and grading is not necessary.
Disposal	Timber and brush disposal options will be subject to agreements with occupants and the Crown. Merchantable timber will be salvaged as determined in the Timber Salvage Plan (Pipeline EPP [Volume 6B]). Residual woody materials will be disposed of by burning or chipping, unless otherwise directed by the Lead Environmental Inspector, Inspector(s) or the appropriate regulatory authority (*e.g.*, Alberta Environment and Sustainable Resource Development [AESRD], BC Ministry of Forests, Lands and Natural Resource Operations and/or British Columbia Ministry of Environment [BC MOE]). In the Lower Mainland where air quality is an issue and along highways where smoke may be a hazard, residual woody materials will be mulched in place or hauled to an approved disposal location.
Topsoil or Root Zone Material Salvage	In general, topsoil will be salvaged to ensure that the soil productivity is maintained in agricultural and grassland areas and root zone material will be salvaged where grading is necessary on treed lands. The width and depth of topsoil or root zone material salvage depends on a number of factors including the land use, soil conditions, microtopography, landowner and regulatory authority requests, and grading requirements. Equipment used during topsoil or root zone material handling activities may include bulldozers, graders and excavators.

TABLE 2.2-1 Cont'd

Construction Phase	Associated Activities
Grading	Following topsoil or root zone material salvage, grading will be conducted on irregular ground surfaces (including temporary workspace) to provide a safe work surface. Graders, excavators and bulldozers will be used for this activity. Ripping or blasting might be required where hard bedrock is encountered.
Stringing and Welding	The pipe will be transported by truck from stockpile sites to the construction right-of-way. The pipe will be bent, lined-up, welded, joint-coated and inspected, before being lowered into the trench. Is it anticipated that a mix of manual and mechanized welding will be used depending on terrain and anticipated productivity. Other equipment used during stringing and welding activities includes pipe trucks, booms, pick-up trucks, excavators and x-ray or ultrasonic inspection equipment mounted on pick-up trucks or skids.
Trenching	The trench will be excavated using tracked excavators to a depth sufficient to ensure the depth of cover is in accordance or in excess of applicable codes. The minimum depth of cover for the pipeline will generally be 0.9 m (the pipeline trench will be deeper at watercourse crossings, highway crossings etc.). Railway crossings and paved road crossings will generally be bored.
Lowering-In	The pipe will be lowered into the trench using sideboom tractors and excavators. Trench dewatering might be necessary at certain locations during lowering-in (*e.g.*, to ensure acceptable bedding for pipe, to prevent the pipe from floating or for performing tie-in welds).
Backfilling	Before backfilling, subsurface erosion-control structures such as trench breakers will be installed on steep slopes or long continuous slopes, along with subdrains, where warranted, to control subsurface drainage along the trench. The trench will be backfilled using excavators, graders, bulldozers or specialized backfilling equipment. Backfill material will generally consist of native-trench spoil material. Displaced subsoil will be crowned over the trench to compensate for settlement and any excess trench spoil will be feathered-out over adjacent portions of the construction right-of-way where topsoil or root zone material salvage has occurred. Padding may be necessary where the trench is created in areas of bedrock.
Testing	The pipeline segments will be hydrostatically pressure-tested in accordance with the *NEB OPR*, provincial legislation, codes of practice and guidelines as well as the latest version of CSA Z662. The pipeline will be pressure-tested in sequential segments, using water. Source water is likely to be drawn from the North Saskatchewan, Pembina and McLeod rivers for new pipeline in Alberta, and from the Fraser, Canoe, North Thompson, Thompson, Coldwater, Coquihalla and Sumas rivers for new pipeline in BC. Test water will be withdrawn and released in accordance with Alberta Codes of Practice (*i.e.*, Code of Practice for the Temporary Diversion of Water for Hydrostatic Testing of Pipelines and Code of Practice for the Release of Hydrostatic Test Water from Hydrostatic Testing of Petroleum Liquid and Gas Pipelines)and BC *Water Act* approval conditions. Upon completion, test water will be returned to its source basin. A detailed hydrostatic test plan will be developed and reviewed before the start of the hydrostatic pressure testing program.
Clean-Up and Reclamation	Initial clean-up and reclamation activities along disturbed portions of the construction right-of-way and temporary access trails (shoo-flies) will be initiated following backfilling, once weather and soil conditions permit. Debris remaining following construction will be removed and disposed of in compliance with local regulations. The construction right-of-way will be graded to restore pre-construction contours, where practical, and returned to a stable condition. The topsoil or root zone material will be replaced, with cross ditches and diversion berms installed on moderate and steep slopes to reduce the risk of erosion. On treed lands where erosion is not expected, natural revegetation will be the preferred method of reclamation. Non-cultivated agricultural and native grassland areas will be seeded with an appropriate seed mix unless otherwise directed by landowners or provincial or local authorities.
Watercourse Crossings	Options available for crossing watercourses include trenched (*e.g.*, isolation [dam and pump, flume] and open cut) and trenchless (horizontal directional drill [HDD] and bore) methods. The crossing method chosen will be based on the width, streamflow, channel morphology, subsurface geology, sensitivity and approach slopes. Additional information is provided in the Pipeline EPP (Volume 6B) and the fisheries technical reports (Volume 5C).
Permanent Pipeline Facilities	
Site Preparation	Sites located within the proposed easement will be prepared as part of the pipeline construction activities above. Sites located along the existing active or reactivated easements will involve clearing of snow and/or vegetation where present, salvaging of topsoil or root zone material and grading of the site, where warranted, using equipment similar to that described for construction of the pipeline.
Facility Construction	Once the infrastructure has been installed along the new pipeline or existing pipeline rights-of-way, the area inside the new fence line will be gravelled. The Pressure Control Station, if required, will be constructed entirely within the existing pump station boundary at Hope. Permanent pipeline-related facilities will be constructed as an integrated part of the pipeline construction. Permanent facilities work along the existing active and proposed reactivated segments will require surface disturbance confined to the existing right-of-way easement.
Potential Ancillary Infrastructure	Permanent Access Roads Activities associated with construction of new permanent access roads to the MLBVs (in the event any are required) and the Black Pines Pump Station include: surveying; clearing; salvaging and storing of topsoil or root zone material; grading; installing culverts at the road bar ditches; and clean-up and reclamation. Equipment used during access road construction includes bulldozers and graders. Distribution Power Lines Activities associated with the installation of distribution power lines to the MLBVs (in the event any are required) and the Pressure Control Station, if required, as well as the power lines at Black Pines and Kingsvale pump stations, include: surveying; clearing or mowing of brush; salvaging of topsoil or root zone material; drilling of holes; erecting poles; stringing of new cable; replacing topsoil or root zone material; and clean-up and reclamation. Equipment used to install distribution lines includes backhoes, bulldozers and drill equipment for the poles.

TABLE 2.2-1 Cont'd

Construction Phase	Associated Activities
Reactivated Segments	
Pipeline Inspection, Repairs and Cleaning	Before testing, reactivated pipeline segments will be assessed using in-line inspection tools. Specific locations along the pipeline will be physically inspected and repaired, if required, as determined necessary to ensure integrity. Following inspection, in-line cleaning tools will be used to scrub the pipe walls and remove residual hydrocarbon products and debris.
Testing	Following inspection and cleaning, the pipeline segments will be hydrostatically tested using similar procedures for new pipeline above. Source water is likely to be drawn from the Athabasca, Snaring, Miette and Fraser rivers as well as Moose Lake for the reactivated pipeline segment from Hinton to Hargreaves and from the North Thompson River for the reactivated pipeline segment from Darfield to Black Pines. Discharge water from hydrostatic testing of the previously in-service pipeline segments will require more extensive treatment than new pipeline segments due to the presence of residual hydrocarbons. Holding ponds or tanks will be used to provide storage for the discharge water, which will be treated on-site before release into the environment.
Temporary Facilities	
Site Preparation	Initial site preparation will involve clearing of vegetation where present, salvaging of topsoil or root zone material and grading, where warranted, using equipment similar to that described for construction of the pipeline.
Facility Construction	Sites may be gravelled and/or fenced, depending on site use.
Access	Access to the various types of temporary facilities will be controlled during site use, if warranted, for public safety and to prevent vandalism of equipment and/or facilities.
Facility Dismantle	Any above ground structures (*e.g.*, fencing, buildings) will subsequently be dismantled and removed from the site. Access roads and associated gravel will also be removed.
Reclamation	Reclamation procedures will be initiated following the dismantling of above ground structures using bulldozers, excavators and graders. Debris remaining at temporary facility sites will be removed and disposed of in compliance with local regulations. Site contours will be replaced and the site will be returned to a stable and maintenance-free condition. Depending on the intended land use of the site, topsoil or root zone material will be replaced where salvaged and disturbed areas will be seeded with an appropriate seed mix.
New, Expanded and Reconfigured Pump Stations	
Construction Survey	Activities include staking of the boundaries of the pump station site and temporary workspace as well as marking hot lines and existing utilities. Avoidance areas, such as protected habitats, will be appropriately fenced or flagged.
Clearing and Disposal	Activities associated with vegetation clearing and disposal at pump stations are described above under new pipeline segments.
Topsoil or Root Zone Material Salvage	Topsoil or root zone material, where present, will be salvaged from pump station sites where clearing and grubbing are required. The topsoil or root zone material will be stockpiled in low profile berms or piles adjacent to the site perimeter. The topsoil or root zone material location will be documented for future reference. Equipment used during topsoil or root zone material handling activities may include bulldozers, graders and excavators.
Grading	Following topsoil or root zone material salvage, grading will be conducted on irregular ground surfaces to provide a safe work surface. Graders, excavators, and bulldozers will be used for this activity. Ripping might be required where hard bedrock is encountered.
Piles and Foundations	Once the site is graded, piles will be driven into the ground using pile drivers, where required. In some instances, concrete foundations will be poured using concrete trucks, smoothing equipment, and forms.
Building Installation	Once the piles and foundations are in place, the buildings will be installed. Equipment used during this activity includes cranes, semi-trailers and trucks.
Electrical and Pipeline Connections	The electrical and piping connections will be completed once the buildings have been installed.
Potential Ancillary Infrastructure	Activities associated with construction of the new permanent access road and power line at Black Pines Pump Station and power line at Kingsvale Pump Station are described under permanent pipeline facilities above.
Testing	All systems and processes will be connected and tested. All piping will be pressure tested during fabrication and/or after installation.
Clean-Up and Reclamation	Upon completion of building activities, clean-up and reclamation procedures will be initiated using bulldozers, excavators and graders. Debris remaining at the pump stations will be removed and disposed of in compliance with local regulations. Surface water controls, recontouring, erosion controls and terrain stabilization will be incorporated where necessary. Gravel surfaces will be placed over high-traffic areas of the pump stations (including on-site gravel roads) and fencing will be installed around the sites where none is currently present.
Reactivated Pump Stations	
Inspection, Cleaning and Testing	Reactivation will involve the removal of the existing pumps, motors and valves; inspection, servicing, refurbishment and then reinstallation of these components, testing of the system, and then commissioning of the station, including mechanical, electrical, instrumentation and control systems.
Deactivated Pump Stations	
Inspection and Shut Down	Deactivation will involve shutting-in the pump station; isolating the pump station facilities from the pipeline; purging the pump station facility with nitrogen; maintaining existing power supply; and protecting the equipment as per the manufacturer's recommendations.
Storage Tanks	
Construction Survey	Activities include staking the tank boundaries and temporary workspace as well as marking hot lines and existing utilities.
Clearing and Disposal	Activities associated with vegetation clearing and disposal at terminals are described above under new pipeline segments.

TABLE 2.2-1 Cont'd

Construction Phase	Associated Activities
Topsoil or Root Zone Material Salvage	Topsoil and root zone material, where present, will be salvaged as described above under new, expanded and reconfigured pump stations.
Site Preparation	Following topsoil or root zone material salvage, grading will be conducted on irregular ground surfaces to provide a safe work surface and level tank foundation and to establish suitable drainage at the site. Low wet areas will be dewatered and suitable fill material will be imported as necessary. Graders, excavators and bulldozers will be used for this activity. Ripping may be required where hard bedrock is encountered.
Piles, Foundations and Tank Installation	Once the site is graded, piles will be installed. In some instances, concrete foundations will be poured using concrete trucks, smoothing equipment and forms. Tanks and buildings will be installed on prepared foundations. Secondary containment consisting of compacted clay or a geosynthetic liner will be constructed under and around the tanks. All necessary fire suppression and vapour recovery equipment will be installed. Equipment used during this activity includes welders, cranes, semi-trailers and trucks.
Electrical and Pipeline Connections and Testing	Piping connections will be completed once the tanks have been installed, and all systems and processes will be connected and tested.
Testing	Tanks will be hydrostatically tested. All piping will be pressure-tested during fabrication and/or after installation. Wherever possible, test water will be released to land within a containment structure (*e.g.*, into a lined tank bay). From there, it will be tested for contaminants before being treated and either trucked away or released to a natural water body or the municipal sewer system. If naturally occurring water is likely to be used for an extended period of time (*i.e.*, for multiple tanks), it may need to be treated to prevent the growth of algae or other organic contaminants. Depending on what treatment is used, there may be special requirements for discharge, particularly if the planned discharge is to the environment.
Clean-Up and Reclamation	Upon completion of building activities, clean-up and reclamation procedures will be initiated using bulldozers, excavators and graders. Debris remaining at the terminals will be removed and disposed of in compliance with local regulations. Surface water controls, recontouring, erosion controls and terrain stabilization will be incorporated where necessary. Gravel surfaces will be placed over high traffic areas of the terminals (including on-site gravel roads).
Westridge Marine Terminal	
Construction Survey	Activities include staking all boundaries of the marine terminal land and foreshore footprint and additional temporary workspace as well as marking hot lines and existing utilities.
Dredging	Dredging may be required for foreshore preparation. Equipment used during dredging activities will include barges and clamshell buckets.
Material Disposal	Dredge material will be collected and disposed of in accordance with provincial regulations and municipal bylaws and, if suitable, may be used if suitable for reclamation of the foreshore area and to increase the land base needed for the expansion of the facility.
Dock Construction	Marine structures will likely be supported by tubular steel piles installed into the seabed. Dock structures will be constructed of steel mooring dolphins and catwalks will be constructed of steel that span between the piles. Once the dock structures are completed, the topside equipment such as piping systems, loading arms, vapour recovery piping, and fire protection systems, will be installed. Construction of the docks will mostly be done using floating equipment such as barge-mounted pile drivers and marine derricks.
Existing Dock	Operations at the existing dock are anticipated to continue during construction of the new berths. Once the new docks are in-service, the existing dock will be completely decommissioned and removed. The structures will be removed from the water by removing topside equipment, demolishing the deck structures and extracting the piles from the seabed. If complete removal of the piles is not feasible, they will be cut off at or slightly below the seabed. The demolition material would be removed from site on a barge. Some materials, such as steel and concrete, may be reclaimed and recycled for use in other projects, and some will be disposed in a landfill.
Electrical and Pipeline Connections and Testing	All systems and processes will be connected and tested.
Testing and Inspection	All piping will be pressure-tested during fabrication and/or after installation and all process piping welds will be inspected using either x-ray or ultrasonic methods.
Clean-Up and Reclamation	Upon completion of building activities, clean-up and reclamation procedures will be initiated using barges, bulldozers, excavators and graders. Debris remaining at the terminal will be removed and disposed of in compliance with local regulations. Surface water controls, recontouring, erosion controls and terrain stabilization will be incorporated where necessary. Asphalt or gravel surfaces will be placed over high traffic areas of the terminal (including on-site gravel roads) and fencing will be installed around the sites where none is currently present.

2.2.2 Construction Schedule and Workforce

Pending regulatory approval of the Project, construction of the pipeline and facilities is scheduled over an approximately 24 month period to achieve the planned in-service date of late 2017. Preliminary plans provide for seven pipeline construction spreads, ranging from approximately 34.2 km to 290.4 km in length. It is anticipated that all seven spreads will generally be constructed concurrently during the following consecutive construction seasons: summer 2016; winter 2016/2017; and summer 2017. The length of the construction period for each spread depends on, among other variables, length, land uses, terrain and construction techniques for each spread.

Front-end preparatory activities such as construction right-of-way clearing and access preparation will commence within the first month or second month on any given spread, or earlier to avoid migratory bird windows, followed by topsoil or root zone material salvage, grading, stringing and welding, trenching, pipeline installation, backfilling, machine clean-up and pressure testing. Water crossing installations requiring instream activity will take place outside instream restricted activity periods (RAPs) in Alberta and within least risk windows in BC, unless otherwise approved by the appropriate regulatory authorities for specific watercourse crossings. Segments through wetlands will typically be constructed during dry conditions or frozen conditions to reduce disturbance. Final clean-up and reclamation activities will occur on dry, non-frozen ground throughout summer months of 2017 and 2018, with the exception of inaccessible wet areas, where activities will occur during frozen conditions. Localized remedial activities will occur over the following years for minor restoration repair and maintenance as dictated by weather events.

Pipeline construction activities are progressive. Consecutive phases of the pipeline construction process are expected to overlap as construction progresses along the construction right-of-way within a spread and amongst spreads (*i.e.*, right-of-way preparation, trench excavation, pipeline installation, backfilling and initial clean-up activities will all occur concurrently at different locations along the pipeline route). Crews will be working approximately three months at any given location on the right-of-way. Tie-in locations generally take longer to complete since they are routinely completed last, immediately before and after testing. Certain late stage activities such as testing and final clean-up may be postponed until suitable weather and soil conditions occur.

Activities associated with reactivation of the existing pipeline segments from Hinton to Hargreaves and Darfield to Black Pines will take place over a period of several months, with in-line inspection activities planned for Q3 2016, and excavation, repair and testing activities taking place in Q2 and Q3 of 2017, with operations planned during late 2017.

Construction and equipment installation at pump stations and tank terminals is expected to begin in Q1 2016 and take approximately 8 to 10 months for each pump station and between 14 and 23 months at the terminals, depending on, among other variables, scope, land use and construction techniques for each facility. The construction period for the Westridge Marine Terminal is expected to commence in Q4 2015 with the first berth expected to be in-service by Q3 2017. The second and third new berths are expected to be in-service by late 2017. Demolition of the existing berth is planned to commence in late 2017 after the new berths are commissioned.

A summary of the conceptual construction schedule for each pipeline spread and reactivated pipeline segments is provided in Tables 2.2-2 and 2.2-3, respectively, while Table 2.2-4 summarizes the conceptual construction schedule for pump stations, tanks and the Westridge Marine Terminal. The proposed schedules are subject to modification in response to regulatory approval conditions, outcomes of consultation and engagement, business considerations and market forces, as well as site-specific limitations and constraints, such as the influence of weather conditions on construction activities. For additional information, see Volume 4B.

Notes: 1 Access and clearing activities may start as early as January 2016 at any given location.

2 Activities at Darfield Pump Station (valve modifications and installation of a new scraper trap) will be conducted in conjunction with construction activities at either Blackpool or Black Pines pump stations.

It is estimated that the Project will require a construction workforce to provide over 1,324,000 worker-days in the 2016 to 2017 construction period, or over 60,000 full-time equivalent worker months.

Pipeline spreads will require approximately 400 to 600 workers per spread depending on, among other variables, length and timing of each spread, region and construction techniques utilized. Construction at terminals will require in the range of approximately 60 to 370 workers, depending on the number of new tanks to be installed and other activities. Construction activities at pump stations will require in the range of 55 to 80 workers, depending on the number of new pumps required and other activities. Construction at the Westridge Marine Terminal will require approximately 95 workers over much of the construction period.

Peak construction workforce for the entire Project (*i.e.*, peak activities combined between all Project components) is anticipated to be 4,475 workers during July 2017 (Figure 2.2-1).

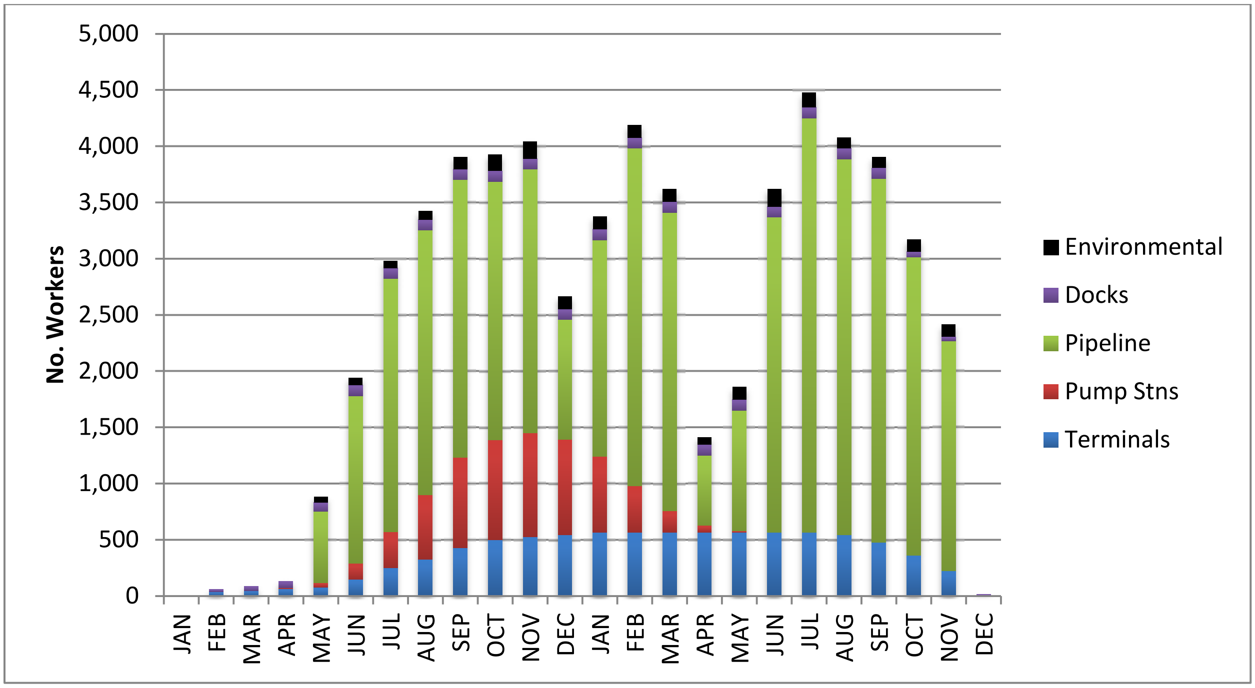

Figure 2.2-1 Estimated Direct Construction Workforce, 2016-2017 (Full-time Equivalent Worker-Months)

Required workforce skills will be varied and will include surveyors, heavy equipment operators, welders, electricians, mechanics, skilled labourers, truck drivers, supervisors, inspectors and monitors. The number of personnel working at any location along the pipeline or facility site will depend on the respective construction phase (*e.g.*, clearing, soil handling, grading, pump and tank installation, dock construction, testing and clean-up).

Large mainline crews construct most of the pipeline within each spread, while smaller specialty crews, working in parallel with mainline crews, complete construction in non-standard sections of the pipeline such as at road, rail, utility and watercourse crossings. Specialty contractors will likely be used for construction in urban or industrial development areas to ensure safe pipeline and facilities installation given the existing utilities and infrastructure situated in the Project area.

2.3 Project Operation

Operations and maintenance activities along the existing TMPL system will be expanded to include the new pipeline and facilities over the operating life of the Project (anticipated to extend beyond 50 years). The following subsections provide an overview of operation and maintenance activities for the Project as well as the anticipated operations schedule and estimated workforce. Additional details regarding Trans

Mountain's operation and maintenance activities, policies, programs and procedures are provided in Volume 4C.

2.3.1 Pipeline

Scheduling of operations and maintenance activities will coincide with periodic aerial and ground patrols of the existing TMPL system and associated facilities. All pipeline patrols are conducted by personnel familiar with the location and operation of the pipeline. Flow in the pipeline will be remotely monitored and controlled from Trans Mountain's existing control centre at the Edmonton Terminal. The pipeline will be maintained from existing bases at Edmonton, Edson, Jasper, Blue River, Clearwater, Kamloops, Hope, Abbotsford and Burnaby. No new pipeline maintenance bases will be required.

Pipeline and right-of-way operations and maintenance activities that could result in potential environmental effects include works associated with regular line patrols, vegetation management and integrity digs.

2.3.2 Pump Stations and Tanks

Routine facility inspections will be performed daily at storage tanks and twice per week at pump stations. The facilities will require periodic mowing of vegetation as well as occasional application of gravel on access roads and the sites. Non-residual herbicides will be used only where mowing and other mechanical methods of vegetation management are impractical, upon approval of the appropriate authority.

All Trans Mountain pump stations and storage tanks have automated leak detection and containment systems that are continuously monitored from the existing control centre at the Edmonton Terminal. Operating staff located at pump stations and terminals are trained in leak detection and emergency response as well as early identification of any potential site hazards such as potential erosion and ground instability. Storage tanks are also taken out of service periodically according to American Petroleum Institute requirements, and are cleaned, inspected and, if required, repaired before being returned back to service.

2.3.3 Westridge Marine Terminal

At the Westridge Marine Terminal, all vessel screening and loading operations have been, and will continue to be, directed by experienced loading masters, who have tanker command experience and are on-site during all vessel loadings. Additional operational details including activities performed by the loading master and preventative and site maintenance activities are provided in Volume 4C.

2.3.4 Operations Schedule and Workforce

Based upon construction beginning in Q1 2016, the operations phase of the Project is expected to begin in Q4 2017.

In addition to the existing Trans Mountain staff, once fully operational, the Project is expected to require 90 full-time personnel, of which 50 are anticipated to be located in BC and 40 are anticipated to be located in Alberta.

2.4 Decommissioning and Abandonment

It is difficult at this time to predict when or how the pipeline and facilities will be decommissioned and abandoned at the end of the Project's useful life. The existing TMPL system has been operating successfully for 60 years and will be safe and reliable for many more as a result of continuing proactive maintenance and integrity programs. The operational life of the new pipeline is anticipated to be as long or longer.

Trans Mountain is participating in and will comply with the process established by Stream 3 of the NEB Land Matters Consultation Initiative and Reasons for Decision RH-2-2008. In addition, as part of this application, Trans Mountain filed with the NEB a preliminary abandonment plan (see Volume 4C) providing a discussion of the abandonment planning strategy for the pipelines and facilities to be constructed for TMEP. The plan discusses general activities for the types of facilities that would be abandoned in place, abandoned in place with special treatment or removed. The plan also discusses general reclamation objectives and principles that would be applied during abandonment to return the right-of-way and facility sites to a state comparable with the surrounding environment. The methods of abandonment and reclamation that will ultimately be implemented for the Project will be determined at the time the pipeline is removed from operation, however, those determinations will be based on the most current sound scientific studies and accepted industry practice at that time. Any decommissioning or abandonment activities will require prior approval by the NEB and other applicable regulatory authorities. Decommissioning and abandonment is discussed further in Section 7.0, and also in Volume 4C, Section 12.0 Preliminary Abandonment Plan.

3.0 PUBLIC CONSULTATION, ABORIGINAL ENGAGEMENT AND LANDOWNER RELATIONS

Trans Mountain Pipeline ULC (Trans Mountain) has implemented and continues to conduct open, extensive and thorough public consultation, Aboriginal engagement and landowner relations programs. These programs were designed to reflect the unique nature of the Trans Mountain Expansion Project (TMEP or the Project) as well as the diverse and varied communities along the proposed pipeline and marine corridors. These programs were based on Aboriginal community, stakeholder and landowner groups' interests and inputs, knowledge levels, time and preferred method of engagement. In order to build relationships for the long-term, these programs were based on the principles of accountability, communication, local focus, mutual benefit, relationship building, respect, responsiveness, shared process, sustainability, timeliness and transparency.

This section provides a summary of the design of the public consultation (Section 3.1), Aboriginal engagement (Section 3.2) and landowner relations (Section 3.3) programs, as well as outcomes specific to biophysical elements considered in the Environmental and Socio-economic Assessment (ESA). The full description of the public consultation, Aboriginal engagement and landowner relations programs is located in Volume 3. The outcomes of the consultation and engagement activities for the pipeline and facilities component of the Project specific to socio-economic elements and for the marine transportation component of the Project that was assessed pursuant to the NEB's instruction in their List of Issues, issued July 29, 2013, are located in other sections and volumes of the application. Table 3.0-1 provides information on where these other consultation and engagement considerations are located.

TABLE 3.0-1

CONSULTATION INFORMATION LOCATION

Consultation Information	Application Location
Pipeline and Facilities	
Public Consultation	Volume 3A Volume 5B Section 3.1
Aboriginal Engagement	Volume 3B Volume 5B Section 3.2
Landowner Relations	Volume 3C Volume 5B Section 3.3
Marine Transportation	
Public Consultation	Volume 8A Section 3.1
Aboriginal Engagement	Volume 8A Section 3.2

3.1 Public Consultation

The principles of the stakeholder engagement program are based on public input as well as various stakeholder groups' interests, knowledge levels, time and preferred method of engagement. This subsection provides information on the stakeholder engagement program for the pipeline corridor and describes how stakeholder and public comments relating to the ESA were gathered as well as how these comments have been incorporated into the application.

3.1.1 Design of Public Consultation Program

As part of the stakeholder engagement program, Trans Mountain has taken on an open, extensive and thorough public consultation process, commonly known as stakeholder engagement. Engagement touched on all aspects of the Project along the proposed pipeline corridor between Strathcona County, Alberta (near Edmonton, Alberta) and Burnaby, BC and marine communities from Nanaimo to Sooke, Vancouver Island and Salt Spring Island, BC. Trans Mountain has reached out to the general public, community and business organizations, community leaders, elected officials and environmental groups to receive their input. Open houses and public presentations provided opportunities for public input and queries.

The Project team received feedback from public open houses (also referred to as information sessions), workshops, one-on-one meetings, public presentations, online discussion, comment forms, email and phone calls that have helped shape aspects of the Project. Key topics and issues are relayed to the appropriate Project team representative to be considered and incorporated in the application where applicable. For more Information on feedback from all engagement refer to Volume 3. Overall, engagement activities have provided feedback on the following:

- determining the scope of the ESA;
- identifying potential mitigation measures to reduce environmental and socio-economic effects;
- identifying potential benefits associated with the Project; and
- routing alternatives where it is not practical to follow the existing Trans Mountain Pipeline (TMPL) right-of-way.

The stakeholder engagement program is designed to foster participation from members of the public who have an interest in the scope, activities and routing of the Project. The program will seek meaningful input from stakeholders regarding proposed pipeline corridor, environmental effects, and socio-economic effects and benefits. The program will also share timely information with stakeholders to keep them informed throughout the process. Through preliminary evaluation of the pipeline corridor and surrounding communities, stakeholders that have a potential interest in the Project have been identified in the Table 3.1-1.

TABLE 3.1-1

IDENTIFIED STAKEHOLDER GROUPS FOR PIPELINE CORRIDOR

Stakeholder Type	Stakeholder Type Sub-Categories
Government Authorities	• Government of Canada (federal authorities) • Government of Alberta • Government of BC • municipal governments • regional governments • Transit Authority • universities and colleges
Environmental Non-Government Organizations (ENGOs)	• local ENGOs • provincial ENGOs • national ENGOs
Interest Groups	• chambers of commerce • economic development associations • recreation groups • labour groups • local and regional associations and organizations • business/industry associations • agricultural/environmental associations • local interest groups
Industry	• oil and gas industry • pipeline industry • potential suppliers and contractors • other infrastructure (*e.g.*, CN Rail) construction industries • terminal operators in Burrard Inlet (including other product terminals)
Public	• public living or working in pipeline corridor communities • public living outside of pipeline corridor communities

3.1.1.1 Public

The stakeholder engagement program includes public involvement in order to build awareness and understanding of the Project, manage information flow, identify concerns and issues as well as gather public input into Project plans and design. Trans Mountain's target audience included all interested and potentially affected parties along the proposed pipeline corridor.

3.1.1.2 Focus Participants

The stakeholder engagement program involved focused discussions with small groups of directly affected interested stakeholders. Stakeholders had the opportunity to provide feedback on the proposed pipeline corridor as well as important issues related to the ESA. These participants included representatives from local governments, community organizations, economic development organizations, recreational groups, and ENGOs. Through building relationships with the focus participants, Trans Mountain gathered informed input, identified issues or concerns and, where appropriate, developed early mitigation measures.

3.1.2 Geographic Reach of Public Consultation Program

Trans Mountain recognizes that the extensive scope and scale of the Project will result in interest by members of the broader public as well as stakeholders directly affected by the Project. In order to ensure that communications and engagement opportunities are appropriately tailored to the needs and interests of local communities, engagement activities were divided into pipeline corridor communities (those potentially affected directly by the proposed pipeline and related facilities) and Project-related marine corridor communities that were assessed pursuant to the NEB's instruction in their List of Issues, issued July 29, 2013. In addition, pipeline and marine corridor communities were further divided into the following five regions:

- Alberta;
- BC Interior;
- Lower Mainland/Fraser Valley;
- Mainland Coastal; and
- Island Coastal communities.

As Trans Mountain proceeded through the pre-application phase of the Project, the stakeholder engagement program allowed for the identification of new information and additional stakeholders. The grouping of these communities was completed following preliminary conversations with stakeholders and municipal governments to identify local interests and needs. Table 3.1-2 provides the regional break-down as well as the core communities associated with the proposed pipeline corridor and marine areas.

TABLE 3.1-2

STAKEHOLDER ENGAGEMENT – PIPELINE AND MARINE CORRIDOR COMMUNITIES

Pipeline Corridor			Marine Corridor	
Alberta	BC Interior	Lower Mainland/ Fraser Valley	Mainland Coastal	Island Coastal
• Strathcona County • Hamlet of Sherwood Park • City of Edmonton, • Parkland County • City of Spruce Grove • Town of Stony Plain • Village of Wabamun • Yellowhead County • Town of Edson • Town of Hinton • Municipality (Town) of Jasper	• Village of Valemount • Community of Blue River • Community of Avola • Community of Vavenby • District of Clearwater • Community of Little Fort • District of Barriere • City of Kamloops • City of Merritt • District of Hope* • Regional District of Fraser-Fort George (RDFFG) • Thompson-Nicola Regional District (TNRD)	• District of Hope[1] • Fraser Valley Regional District (FVRD) • City of Chilliwack • City of Abbotsford • Township of Langley • City of Coquitlam • City of Port Coquitlam • City of Burnaby** • City of Surrey • City of Vancouver • Metro Vancouver Regional District[2]	• City of Burnaby[2] • Village of Anmore • Village of Belcarra • City of North Vancouver • City of Port Moody • City of Richmond • City of Vancouver • City of White Rock • Corporation of Delta • District of North Vancouver • District of West Vancouver • Bowen Island Municipality • University Endowment Lands/Metro Vancouver Electoral Area "A" • Metro Vancouver Regional District[2] • Squamish Lillooet Regional District • Village of Lions Bay • District of Squamish	• Corporation of the City of Duncan • City of Nanaimo • Nanaimo Regional District • Alberni – Clayoquot Regional District • Corporation of the City of Victoria • Cowichan Valley Regional District • Corporation of the District of Central Saanich • District of Metchosin • District of North, Saanich • Corporation of the District of Oak Bay • Corporation of the District of District of Saanich • District of Sooke • Islands Trust Areas • Capital Regional District • Sunshine Coast Regional District • Town of Sidney • Corporation of the Township of Esquimalt

Notes: 1 The District of Hope, while a member of FVRD, is allocated for the purposes of stakeholder engagement activities under the BC Interior Region and the FVRD is allocated under the Lower Mainland/Fraser Valley Region.

2 Due to the location of the City of Burnaby and the Metro Vancouver Regional District, these two communities have been engaged under the Lower Mainland/Fraser Valley Region as well as the Mainland Coastal Region.

3.1.3 Phased Activities

The stakeholder engagement program adopted a phased approach to public and stakeholder engagement. Each phase was developed in response to information gathered from the previous phase as well as identified interests and needs. The current stakeholder engagement program consists of six phases which include:

- Phase 1 Engagement: Stakeholder and Issue Identification, May to September 2012;
- Phase 2 Engagement: Public Information and Input Gathering, October 2012 to January 2013;
- Phase 3 Engagement: Community Conversations, February to July 2013;
- Phase 4 Engagement: Feedback to Stakeholders and Application Filing, August to December 2013;
- Phase 5 Engagement: Regulatory Process to In-Service, January 2014 to in-service; and
- Phase 6 Engagement: Operational Consultation.

3.1.4 Stakeholder Engagement Program Execution

The stakeholder engagement program was designed to foster positive relationships with the public and stakeholders as well as provide opportunities for stakeholders to be involved in the engagement process.

Section 3.1.4.1 provides information on the activities that have taken place during the three phases of engagement activities conducted from the time of the Project announcement in May 2012 to the end of Phase 3 on July 31, 2013.

3.1.4.1 Enhance Communications Initiatives

The communications initiatives support the consultation activities by providing notification about the various engagement opportunities including public open houses, Community Workshops and online discussion activities.

From producing printed newsletters to talking about Project details on social media channels to answering public and media inquiries to participating in speaking opportunities, the stakeholder engagement and communications team uses a variety of methods to reach various audiences. The communications initiatives include:

- a comprehensive website with information about various components of the Project and the industry;
- proactively distributing Project updates via email to people who have signed up through the Project website, at open houses, or through other means;
- Twitter and YouTube posts to reach people who use social media channels;
- providing various forums for people to ask questions: toll-free phone line; email; a website question and answer forum; and direct letters;
- a full media relations service including a dedicated media toll-free phone line; and
- a modest advertising campaign aimed at notifying people about ways they can engage with members of the Project team – in person or online.

The Trans Mountain stakeholder engagement and communications team provides those interested in the Project with a range of sources of information and platforms to encourage discussion and education. For more information on the Project stakeholder engagement and communication strategy, refer to Volume 3A.

Phase 1 Engagement: Stakeholder and Issue Identification, May to September 2012

The first phase of engagement focused on Project introduction and the flow of Project information to government, municipalities and key stakeholders. This phase included identifying stakeholders with interest in participating in the engagement program, local community interests and concerns, and appropriate consultation methods. Trans Mountain provided information through mail and email, website posts as well hand delivering information to stakeholders at Project introduction meetings.

Phase 2 Engagement: Public Information and Input Gathering, October 2012 to January 2013

Phase 2 of the Trans Mountain Engagement Program continued the outreach and discussions with municipalities and other stakeholders. In addition, Trans Mountain conducted a series of public information sessions along the proposed pipeline corridor. Content and format varied by the needs and interests of the communities. Trans Mountain provided Project overview information as well as the scope of the pipeline corridor biophysical assessment. Trans Mountain focused on engaging the public through open house style information sessions and seeking input through conversation, feedback forms, online discussion, and a Project-specific twitter channel. Trans Mountain continued meeting with stakeholders and government representatives.

Trans Mountain attended the 2012 Union of British Columbia Municipalities (UBCM) convention in Victoria, BC, and later hosted a full day open house for UBCM delegates. In addition, Trans Mountain sent letters to local governments along the marine corridor offering individual meetings with representatives in Victoria, for which seven meetings with councils were arranged.

Environmental Non-Government Organizations

Research and early conversations guided the scope of engagement with stakeholders on environmental issues in different ways, based on the level of control and responsibility Trans Mountain has over each issue. Some common marine environmental concerns identified by stakeholders in this phase include effects of marine oil spills on the biodiversity, the fishery industry, human health as well as costs related to clean-up of potential marine spills, among others.

Public Open Houses

Public open houses were structured as drop-in events where members of the public were invited to attend, gain information and ask questions about the Project. Project information was displayed on story boards positioned throughout the venue. Technical experts including representatives from environment, routing, geotechnical, regulatory, operations, stakeholder engagement and media relations were on hand to answer questions and receive comments and concerns from attendees. In addition, material was available as handouts and posted on the Project's website.

Phase 3 Engagement: Community Conversations, February to July 2013

Phase 3 of the Trans Mountain Engagement Program focused on seeking meaningful input from stakeholders on the proposed approach to the ESA. Engagement meetings in this phase of the program included ESA Workshops, Community Workshops as well as focused public information sessions in some communities on proposed Project routing. Community meetings focused on sharing updated Project information, seeking meaningful input from affected stakeholders on proposed route alternatives in areas where it is likely that the proposed pipeline corridor will deviate from the existing TMPL right-of-way and seeking input from local stakeholders on potential Project effects and mitigation measures.

Environmental Non-Government Organizations

Engagement efforts in Phase 3 focused on local environmental groups based in communities along the pipeline and shipping corridor. Feedback from these local groups was particularly important during routing and ESA Workshops where local environmental knowledge helped to identify issues of concern in study areas as well as possible mitigation measures and possible compensation or net benefit initiatives to consider as part of the overall Project proposal.

ESA Workshops

In Phase 3, Trans Mountain hosted ESA Workshops to provide information on the proposed approach used for the Project ESA and to seek input from stakeholders regarding study approach, methodology and regions. The proposed Project traverses distinct geographic regions that include diverse ecosystems ranging from grasslands to rainforest. Regional experts were asked to attend ESA Workshops in representative communities in order to capture specialist knowledge for each region. The ESA Workshops targeted local and regional subject matter experts from municipal, federal and provincial governments, local ENGOs and other environmental interest groups. Trans Mountain hosted the ESA Workshops for Alberta in Edmonton, Alberta; and for BC in Kamloops, Surrey and Abbotsford.

The Project team provided attendees with a proposed overview of the ESA approach for the Project and sought the feedback of attendees on particular modules of the ESA including air, land and water. The ESA Workshop in Abbotsford, BC focused on soil and agriculture as these subjects were of greatest concern to the community. Input was solicited online for 2 weeks after each workshop; information presented at the workshops was made available online following each session. Feedback received at these sessions was shared with the relevant environmental disciplines and was considered in setting the scope and methodologies for the Project's biophysical assessment.

Community Workshops

In Phase 3, Trans Mountain hosted a series of Community Workshops along the proposed pipeline corridor to provide an opportunity for local stakeholders to receive updated information and provide feedback on issues and concerns relative to their community. Community Workshops were attended by stakeholders that held expertise on community interests, the environment, economic activity, recreation and land use. Participation included municipal representatives, local community representatives, business groups, recreational representatives and guides and outfitters. Community Workshops comprised of ESA poster presentations and oral presentations on land, air, water, and human activity as well as an exit survey. All information presented at the workshops was made available online the day following each session and was live for 3 weeks. Trans Mountain hosted Community Workshops for Alberta in Edmonton, Parkland County (Wabamun), Edson and Hinton. Trans Mountain hosted Community Workshops for BC in Valemount, Blue River, Clearwater, Kamloops, Merritt, Hope, Chilliwack, Abbotsford, Langley, Surrey, Coquitlam and Burnaby.

Phase 4 Engagement: Feedback to Stakeholders and Application Filing, August to December 2013

The goals of the Phase 4 stakeholder engagement program include sharing the results of the marine studies, environmental field studies with stakeholders, commencing communications on the application and next steps for engagement and communications following the filing of the application. Further details regarding refined Project plans prior to filing the application with the NEB will be shared with the public.

Engagement activities will include community and economic benefit presentations in conjunction with the Chambers of Commerce, attending events, one-on-one meetings, emergency response workshops and presentations/speaking opportunities. Meetings with local government and interested parties will be ongoing. Trans Mountain will continue digital engagement efforts and seek out more public opportunities to share information and gather feedback.

Planned Consultation on Reactivation

Trans Mountain is planning to reactivate two 610 mm (24 inch) segments of existing pipeline (from Hinton, Alberta to Hargreaves, BC and from Darfield, BC to Black Pines, BC) as part of the TMEP. Stakeholders include Parks Canada, the Town of Jasper, the Town of Hinton, Yellowhead County, BC Parks, local stewardship groups and the public. Project planning is currently underway and further stakeholder input will be sought as technical requirements for deactivation are further defined.

Phase 5 Engagement: Regulatory Process to In-Service, January 2014 to In-Service

Additional engagement phases will be developed to support the regulatory process and, if successful, the construction phases of the Project. The goals of these engagement phases will include sharing results of any new studies or work being completed on the Project, to communicate any changes to Project plans, to share information with stakeholders on the regulatory process and to engage on construction effects and mitigation measures. Additional objectives include communicating about the benefits of the Project to local stakeholders and engaging on environment offsets.

Engagement continues with environmental groups related to the Project in regard to refining environmental inputs for consideration in the ESA process, feedback on the approach to ecological compensation (conservation offsets), and the development and communication of geographic spill response plans. Engagement also continues with coastal stakeholders and Aboriginal communities related to environmental aspects of the Project. Trans Mountain is also encouraging new relationships between these groups and certified spill responders so that more information can be shared about areas of high ecological value on BC's southwest coast.

Phase 6 Engagement: Ongoing Operational Consultation, Post-Construction throughout Operational Life

Trans Mountain is committed to respectful, transparent and collaborative interactions with communities to develop long term effective relationships. Once the pipeline becomes operational, engagement opportunities will continue through the hosting open houses, providing newsletters and Project updates, making safety and public awareness presentations, participating in community events, regulatory processes and through ongoing informal meetings with stakeholders.

Initiatives to be activated during this phase will be developed in the lead up to construction. Trans Mountain is, however, committed to ongoing consultation in the communities in which it operates.

3.1.5 Summary of Outcomes of the Public Consultation Program as it Relates to Biophysical Elements

Trans Mountain designed the stakeholder engagement program to involve people who may be affected or have interest in the Project. Through the first three phases of engagement, Trans Mountain has had the opportunity to provide Project information through various methods and receive general comments as well as specific information for route and Project planning. Trans Mountain has engaged stakeholders in dialogue to discover the social and environmental issues or concerns that matter most to them. Trans Mountain has tracked these conversations and relayed the key topics to the Project representative to be considered and incorporated in the application where applicable. Tables 3.1-3 to 3.1-13 provide information on the key topics relating to the biophysical component of the ESA and where these topics are addressed in the application.

3.1.5.1 Physical and Meteorological Environment

TABLE 3.1-3

INTERESTS OR CONCERNS RELATED TO PHYSICAL AND METEOROLOGICAL ENVIRONMENT

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Geotechnical Concerns	Potential environmental effects, geotechnical conditions, and constructability concerns have been identified along the proposed pipeline corridor to ensure the Project can be built and operated safely. The focus of routing is to find the best route for the proposed pipeline so it can be built next to the existing TMPL pipeline where possible, and to minimize effects to properties. It is important to note that the assessment corridor is for the purposes of environmental and engineering studies and does not reflect the ultimate width or footprint of the proposed construction or new line. A discussion of geotechnical issues is provided under physical and meteorological environment in Sections 5.1 and 7.2.1.	Volume 5A Sections 4.0, 5.1 and 7.2.1
Geology at Hope-Bridal Falls	Detailed routing and engineering design has not yet begun. In due course, each segment of the proposed pipeline corridor will be carefully assessed by appropriate professionals for potential instability and hazards which may affect the construction and operation of the pipeline. Where necessary, steps will be taken to mitigate the effects of potential hazards. Where possible, steps to mitigate disturbances will be applied depending on circumstances of individual owners.	Volume 5A Sections 4.0, 5.1 and 7.2.1

3.1.5.2 Soil and Soil Productivity

TABLE 3.1-4

INTERESTS OR CONCERNS RELATED TO SOIL AND SOIL PRODUCTIVITY

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Soil conservation and erosion in the transportation utility corridor (TUC), especially community gardens and local recreational trails	Where present in non-forested areas, topsoil or root zone material will be salvaged to ensure that soil productivity is maintained. The width and depth of topsoil or root zone material salvage will depend on the land use, soil conditions, microtopography, regulatory authority requests and grading requirements. Any salvaged topsoil or root zone material will be separated from spoil piles and stored along the construction right-of-way and at facility sites in low-profile berms or windrows. A discussion of soils is provided under soil and soil productivity in Sections 5.2, 7.2.2 and 7.2.4. Mitigation measures are outlined in the Pipeline and Facilities Environmental Protection Plans (EPPs) (Volume 6B and 6C).	Volume 5A Sections 5.2, 7.2.2 and 7.4.2 Volume 5C Soils Technical Report Volume 6B Volume 6C

TABLE 3.1-4 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Potential erosion along and near the right-of-way, and potential increases in erosion due to clearing.	If wind or water erosion is evident during the construction phase of the Project, contractor equipment and personnel will be made available to control the erosion. During the construction phase, the Environmental Inspector, in consultation with Trans Mountain's environmental staff, will determine appropriate procedures to be implemented to control soil erosion and other soil handling problems that may be encountered. Similar procedures will be followed during the operational phase. A discussion of soils and the potential for erosion is provided under soil and soil productivity in Sections 5.2, 7.2.2 and 7.2.4. Mitigation measures for soil erosion are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.2, 7.2.2 and 7.4.2 Volume 5C Soils Technical Report Volume 6B Volume 6C
Restoration of agricultural lands	Soils studies are completed to determine the type and condition of soils along the proposed pipeline corridor. The studies for the Project will mostly involve a ground based agricultural soil survey program. The surveys are designed to meet NEB requirements and to assist in Project design, construction and restoration. A discussion of soils is provided under soil and soil productivity in Sections 5.2, 7.2.2 and 7.2.4 of Volume 5A while agricultural land use is discussed under human occupancy and resource use (HORU) in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.2, 6.0, 7.2.2 and 7.4.2 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Soils Technical Report Volume 5D Agricultural Assessment Technical Report Volume 6B Volume 6C
Disturbance to soils and crops	Where present in non-forested areas, topsoil or root zone material will be salvaged to ensure that soil productivity is maintained. The width and depth of topsoil or root zone material salvage will depend on the land use, soil conditions, microtopography, regulatory authority requests and grading requirements. Any salvaged topsoil or root zone material will be separated from spoil piles and stored along the construction right-of-way and at facility sites in low-profile berms or windrows. Equipment used during topsoil or root zone material handling activities will include bulldozers, graders and backhoes. A discussion of soils is provided under soil and soil productivity in Sections 5.2, 7.2.2 and 7.2.4 of Volume 5A while agricultural land use is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.2, 6.0, 7.2.2 and 7.4.2 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Soils Technical Report Volume 5D Agricultural Assessment Technical Report Volume 6B Volume 6C

TABLE 3.1-4 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Invasion or spread of clubroot disease	Generally, the best available mitigation is to clean equipment involved in topsoil handling so that topsoil is not carried from landowner to landowner and/or from county to county. As presented in the Alberta Clubroot Management Plan (Alberta Agriculture and Rural Development 2010), and the Canadian Association of Petroleum Producers (CAPP) Best Management Practices: Clubroot Disease Management (2008), clubroot disease prevention involves a phased approach, with progressively more aggressive cleaning activities. In order, cleaning activities include: • removing most or all soil from equipment (*i.e.*, basic shovel cleaning and/or shovel and compressed air cleaning); • washing equipment with a power washer (preferably with hot water or steam); and • misting equipment with a weak disinfectant (one to two per cent bleach solution). Basic shovel and sweep cleaning stations are recommended between cultivated fields (*i.e.*, at changes in land use, landowner and/or road crossings) along the right-of-way as a relatively inexpensive way to reduce the potential spread of clubroot disease and weeds. Power wash and misting, are used together to prevent the spread of clubroot disease where risk is high or clubroot exists within the quarter section. Any site that warrants a power wash is considered worthwhile of cleaning with a bleach solution as well. There is less risk of spreading the disease when working on subsoil. Full right-of-way stripping has been used as a method of prevention. There is an expectation from some regulatory authorities that when landowners request special mitigation on their land that they be conducting the same practices on their land with their own equipment or the equipment they hire. Further mitigation is provided in the Pipeline EPP (Volume 6B) and is discussed under soil and soil productivity in Sections 5.2 and 7.2.2.	Volume 5A Sections 5.2 and 7.2.2 Volume 6B

Sources: Alberta Agriculture and Rural Development (2010), CAPP (2008)

3.1.5.3 Water Quality and Quantity

TABLE 3.1-5

INTERESTS OR CONCERNS RELATED TO WATER QUANTITY AND QUALITY

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Environmental effects of freshwater spills	Trans Mountain has comprehensive spill response plans in place for the TMPL and associated facilities. These plans are constantly being updated to keep them current and are regularly practiced through deployment exercises. While the specific strategies used in response to a spill will vary depending on the circumstances, the primary objectives in all cases is to ensure safety and to minimize environmental damage. There are a range of strategies available to achieve these objectives including mechanical recovery (using skimmers), *in situ* burning (controlled burning of the oil), and dispersion (use of dispersing agents to dilute and disperse the oil reducing its concentration). To ensure there are sufficient funds to remediate a spill, Trans Mountain is covered by insurance necessary to respond to all spills or releases from Trans Mountain pipelines and facilities. KMC monitors the insurance program continuously, and makes annual adjustments as necessary to ensure adequate coverage. In the event of a release, and in addition to prevention measures, steps would be taken to minimize the consequence of a release by quickly shutting down and isolating the damaged section of the pipeline or facility. Trans Mountain has developed comprehensive emergency response procedures that control centre and local operators must follow. These procedures, together with aerial and ground patrols, calls from the public to Trans Mountain's toll-free emergency number, and continuous supervisory control and data acquisition (SCADA) monitoring and leak detection systems combine to form the first line of defense in reducing the consequences of a spill. The SCADA and leak detection systems continuously monitor the pipeline for changes in operating parameters that would indicate a possible leak. Trans Mountain owns, maintains and operates dedicated spill response equipment at strategic points along the TMPL system corridor. Oil spill containment and recovery (OSCAR) units are located at Trans Mountain facilities in Edmonton and Jasper, Alberta, and in Blue River, Kamloops, Hope and Burnaby, BC. Each OSCAR unit contains about 300 m of oil recovery boom and support equipment, including a river jet boat for deployment. All equipment is helicopter transportable for delivery to remote locations not accessible by road. Specialized equipment has been developed in-house by Trans Mountain employees for intercepting and recovering oil, if required, from beneath the ice on frozen rivers and lakes. This equipment is stored in the Jasper and Edmonton OSCAR units.	Volume *7*
Potential effects of increased erosion on water bodies	If wind or water erosion is evident during the construction phase of the Project, contractor equipment and personnel will be made available to control the erosion. During the construction phase, the Environmental Inspector(s), in consultation with Trans Mountain's environmental staff, will determine appropriate procedures to be implemented to control soil erosion and other soil handling problems that may be encountered. Similar procedures will be followed during the operational phase. A discussion of potential erosion to waterbodies is provided under water quality and quantity, fish and fish habitat and wetlands in Sections 5.3, 5.7, 5.8, 7.2.3, 7.2.7 and 7.2.8. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.3, 5.7, 5.8, 7.2.3, 7.2.7 and 7.2.8 Volume 5C Fisheries (Alberta) Technical Report Fisheries (British Columbia) Technical Report Wetland Evaluation Technical Report Volume 6B
Groundwater/Hydrology/ Water Quality/Quantity Effect on private wells and potable water supplies Personal wells (Mt. Lehman, Sumas Prairie, Bradner) Concerns about Fraser Valley aquifer(s)	Trans Mountain has assessed water quality and/or quantity changes to nearby groundwater which may result in adverse effects for other stakeholder or environmental receptors. Trans Mountain reviewed existing geological, hydrogeological and other information to determine potential hydrogeological conditions along the pipeline right-of-way and proposed facilities; geographic information system (GIS) mapping and assessment strategies were applied. Trans Mountain developed site-specific hydrogeological investigation activities that included field verified surveys, hydraulic response testing, monitoring requirements and water quality parameter surveys. A discussion of groundwater quality and quantity is provided under water quality and quantity in Sections 5.3 and 7.2.3. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.3 and 7.2.3 Volume 5C Groundwater Technical Report Volume 6B

TABLE 3.1-5 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Precautions taken to protect streams and lakes (*e.g.,* valves)	The number of Emergency Shutoff Valves (ESVs) and Mainline Block Valves (MLBVs) for the proposed line has not yet been determined. The number and locations of ESVs and MLBVs will be guided by modeling studies that factor in local conditions and potential consequences. As Trans Mountain develops a detailed design and engineering work, the final locations of the valves will be designed to protect sensitive areas and minimize effects that are identified in the routing and design process. Other mitigation measures to protect water quality and quantity during construction are discussed under water quality and quantity in Section 7.2.3 and in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.3 and 7.2.3 Volume 6B
Water table is naturally high and there are buried springs along the west side of Edmonton	In the AESRD Water Well database, there is one spring noted on the west side of Edmonton (ID#88953) near the North Saskatchewan River (about 900 m from the centre of the proposed pipeline corridor). In that area (southern portion of the west side of Edmonton), the surficial materials contain shallow sand and gravel and are of higher permeability, thereby increasing the risk for potential contamination of groundwater. With regard to mitigation of concerns around springs, Trans Mountain will develop a mitigation plan commensurate with site-specific conditions. During construction, Trans Mountain will avoid blasting in proximity to the spring and consider other engineering mitigation measures.	Volume 5A Sections 5.3 and 7.2.3 Volume 5C Groundwater Technical Report

3.1.5.4 Air Emissions and Greenhouse Gas Emissions

TABLE 3.1-6

INTERESTS OR CONCERNS RELATED TO AIR EMISSIONS AND GREENHOUSE GAS EMISSIONS

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Potential odours emitted during construction and operations of the proposed pipeline hold the potential to be a nuisance	Petroleum odours can be a nuisance for Trans Mountain neighbours, and sometimes they can also signal a problem with operations. Trans Mountain investigates all odour reports since safe operations and protection of the environment are key to the business. Trans Mountain strives to minimize the effects of operations on neighbours by incorporating odour mitigation measures in day-to-day activities and Project work. In addition, Trans Mountain continues to take steps to enhance early leak detection system(s) and air monitoring/sampling protocol(s). Trans Mountain is looking into procuring technology to facilitate automated calls to residents in the area in the event of an emergency. A discussion of odours is provided under air emissions in Sections 5.4, 6.0 and 7.5.4. Mitigation measures are outlined in the Facilities EPP (Volume 6C).	Volume 5A Sections 5.4, 6.0 and 7.5.4 Volume 5C Air Quality and Greenhouse Gas Technical Report Volume 6C
Dust in the air due to construction is perceived to have potential effects on recreation and nearby neighbourhoods	From the commencement of the surveying and staking of the right-of-way to the final clean-up, a particular parcel of land could be disrupted for approximately 3 months. This timing is affected by many variables, however, every effort is made to minimize any effects to landowners. In areas where there may be a concern regarding the safety of the public, restricted areas are established. Noise, dust and other disturbances will be mitigated to avoid the effects on people near the construction. The issue of dust is provided as part of the criteria air contaminants discussion under air emissions in Sections 5.4 and 7.2.4 of Volume 5A. In addition, dust as a sensory disturbance to residents, recreational users and its potential effects on agricultural crops is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.4 and 7.2.4 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Air Quality and Greenhouse Gas Technical Report Volume 5D Agricultural Assessment Technical Report Socio-Economic Technical Report Volume 6B Volume 6C

3.1.5.5 *Acoustic Environment*

TABLE 3.1-7

INTERESTS OR CONCERNS RELATED TO ACOUSTIC ENVIRONMENT

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Noise pollution during construction Increase in noise from new pump stations	Noise from construction of the Project has the potential to affect a variety of land users including users of parks and protected areas, Aboriginal traditional areas, residential areas and outdoor recreation areas. The potential effects on human receptors are not anticipated to extend beyond the Acoustic Environment local study area. Trans Mountain will ensure equipment is well-maintained during construction to minimize air emissions and unnecessary noise. Additionally, Trans Mountain will restrict the duration that vehicles and equipment are allowed to sit and idle to less than 1 hour unless air temperatures are less than 0°C. Trans Mountain recognizes that many regional changes have occurred since the pipeline was installed over 60 years ago including urban encroachment near some of its existing pump stations and terminals and is aware that noise during operations is of concern to nearby residents. Ambient sound surveys representative of sound levels at noise receptors and existing facilities were conducted and, all noise level results were compared to Alberta Energy Regulator's *Directive 038 Noise Control* and the BC Oil and Gas Commission's (OGC's) *Noise Control Best Practices Guideline*. Standard mitigation plus noise-specific mitigation measures will be implemented. A discussion of noise during construction operations is provided under acoustic environment in Sections 5.6, 6.0, 7.2.6, 7.4.6 and 7.5.6 of Volume 5A. In addition, noise as a sensory disturbance to residents and other land users is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.6, 6.0, 7.2.6, 7.4.6 and 7.5.6 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Terrestrial Noise and Vibration Technical Report Volume 5D Socio-Economic Technical Report Volume 6B Volume 6C
Vibrations caused during pipeline construction	From the commencement of the surveying and staking of the right-of-way to the final clean-up, a particular parcel of land could be disrupted for approximately 3 months. This timing is affected by many variables, however, every effort is made to minimize potential effects to landowners. In areas where there may be a concern regarding the safety of the public, restricted areas are established. Noise, dust and other disturbances will be mitigated to avoid the effects on people near the construction. The issue of noise vibration is provided under acoustic environment in Sections 5.6 and 7.2.6 of Volume 5A. In addition, noise as a sensory disturbance to residents and other land users is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.6 and 7.2.6 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Terrestrial Noise and Vibration Technical Report Volume 5D Socio-Economic Technical Report Volume 6B

3.1.5.6 Fish and Fish Habitat

TABLE 3.1-8

INTERESTS OR CONCERNS RELATED TO FISH AND FISH HABITAT

<table>
<tr><th>Summary of Interest or Concern</th><th>Response Summary</th><th>Where Issue is Addressed in the Application</th></tr>
<tr><td>Crossing methods and fish habitat disruption at the North Saskatchewan River, Blackmud and Whitemud creeks</td><td rowspan="2">Crossing methods specific to each watercourse will be determined in consultation with engineering and environmental specialists, as well as applicable regulatory authorities.
Crossings of wetlands and watercourses will be planned during suitable ground and weather conditions, with the consideration for sensitive fish and wildlife timing windows. Additionally, water quality will be monitored during all instream activity. Each watercourse will be approached correctly so the cumulative effects of changes to all the crossings and the surrounding watershed will be limited.
A summary of the watercourse crossings for the Project are provided in the Fisheries (Alberta) Technical Report, the Fisheries (BC) Technical Report and in the Pipeline and Facilities EPPs (Volumes 6B and 6C). Further discussion and mitigation measures to be implemented at watercourse crossings are mentioned under fish and fish habitat in Sections 5.7, 7.2.7 and 8.6.</td><td rowspan="2">Volume 5A

3.1.5.8 Vegetation

TABLE 3.1-10

INTERESTS OR CONCERNS RELATED TO VEGETATION

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Concern about changes to, and restoration of native vegetation composition	During the 2012 and 2013 field seasons, a number of environmental and engineering field programs were conducted to assess existing conditions and types of land use in the Project area, as well as identify possible socio-economic effects. These programs occurred in both Alberta and BC, and involved the work of a number of teams in various disciplines. Trans Mountain will fulfill all filing requirements in the NEB *Filing Manual*. Lands in Alberta, and lands outside the Agricultural Land Reserve in BC, will be reclaimed with native and non-native seed mixes developed for the Project that are based on vegetation field survey data and will follow consultation with landowners/lessees or appropriate regulatory authorities. Revegetation of lands in the Agricultural Land Reserve in BC will be undertaken in accordance with Schedule B, Site Reclamation Requirements in the *Agricultural Land Reserve Act*. Natural revegetation will be allowed in forested areas where erosion is not anticipated. Remedial and monitoring activities typically extend for a number of years following construction to ensure areas disturbed during construction are satisfactorily restored. Further discussion is provided under vegetation in Sections 5.9 and 7.2.9 while post-construction environmental monitoring is discussed in Volume 6A. Mitigation measures for vegetation are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report Volume 6A Volume 6B
Potential introduction of weeds by construction crews or equipment and measures for vegetation management along existing TMPL as well as new rights-of-way	Post-construction environmental monitoring and ongoing right-of-way maintenance will continue with efforts such as weed management, seeding and planting in selected areas. Mitigation measures are discussed under vegetation in Sections 5.9 and 7.2.9 and in the Pipeline EPP (Volume 6B) while post-construction environmental monitoring is discussed in Volume 6A.	Volume 5A Sections 5.9 and 7.2.9 Volume 6A Volume 6B
Visual effects of the right-of-way if it is left too exposed	Trans Mountain will construct soil berms planted with non forage woody species and install tree/shrub plantings at potential access points and viewsheds to the pipeline corridor to provide a visual screen to the proposed pipeline corridor.	Volume 6B Volume 6C
Clear cutting and vegetation management in the neighbourhoods of Callingwood and Brander Gardens Poor vegetation management along the TUC in Edmonton	Vegetation management on the right-of-way is an integral part of a comprehensive approach to pipeline safety. It allows Trans Mountain to protect the pipeline, ensure public safety, and provide access for maintenance, inspections and emergency response. Vegetation management is a planned process which Trans Mountain conducts regularly and has done before in other areas along the proposed pipeline corridor. Further discussion of mitigation measures for vegetation can be found in the Pipeline EPP (Volume 6B) while post-construction environmental monitoring is discussed in Volume 6A.	Volume 6A Volume 6B

TABLE 3.1-10 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Tree removal and vegetation management along existing TMPL and new rights-of-way Right-of-way width and tree removal Revegetation along the right-of-way	Trees, stumps, brush and other vegetation will be cleared from the construction right-of-way; temporary work sites; and permanent facilities that are not located on existing TMPL previously cleared easements. Timber harvesting and/or land clearing and debris disposal activities will be coordinated according to Provincial legislation or agreements. Where present in non-forested areas, topsoil or root zone material will be salvaged to ensure that soil productivity is maintained. The width and depth of topsoil or root zone material salvage will depend on the land use, soil conditions, microtopography, regulatory authority requests and grading requirements. Any salvaged topsoil or root zone material will be separated from spoil piles and stored along the construction right-of-way and at facility sites in low-profile berms or windrows. Equipment used during topsoil or root zone material handling activities will include bulldozers, graders and backhoes. Lands in Alberta, and lands outside the Agricultural Land Reserve in BC, will be reclaimed with native and non-native seed mixes developed for the Project that are based on vegetation field survey data and will follow consultation with landowners/lessees or appropriate regulatory authorities. Revegetation of lands in the Agricultural Land Reserve in BC will be undertaken in accordance with Schedule B, Site Reclamation Requirements in the *Agricultural Land Reserve Act*. Restoration and monitoring activities typically extend for a number of years following construction to ensure areas disturbed during construction are satisfactorily restored. Further discussion of mitigation measures for vegetation can be found in the Pipeline and Facilities EPPs (Volumes 6B and 6C) while post-construction environmental monitoring is discussed in Volume 6A.	Volume 6A Volume 6B Volume 6C
Disturbance to ecosystems including grasslands surrounding the pipeline	Trans Mountain is fully committed to environmental management, protection and stewardship of the land during the construction and operations of all its facilities. A comprehensive ESA has been completed for the Project. Over 30 types of environmental surveys have been completed by local and regional biologists and resource specialists in support of the ESA. Species of special status have been identified and assessed as part of this Project. Pipeline construction is a sequential series of activities, which do not remain in one area for an extended period of time. EPPs and Environmental Alignment Sheets form part of the application submitted to the NEB, and document the construction right-of-way and provide mitigation strategies to help avoid or minimize environmental effects from construction. Further discussion on grasslands is provided in Section 7.2.9 Vegetation. The Pipeline and Facilities EPPs and Environmental Alignment Sheets can be found in Volumes 6B, 6C and 6E respectively.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report Volume 6B Volume 6C Volume 6E
Identification and preservation of rare plant communities and species at risk as well as the prevention of the introduction/spread of invasive species	Environmental and socio-economic studies have been conducted to assess existing conditions and types of land use in the Project area, as well as possible socio-economic effects. During the 2012 and 2013 field seasons, a number of environmental and engineering field programs were conducted for the proposed Project. These programs took place in both Alberta and BC, and involve the work of a number of teams in various disciplines. The studies included a vegetation field study to record the presence of rare plant communities and species at risk, as well as the identification of weeds. Weed control measures have been introduced as part of the ESA and included in the Pipeline and Facilities EPPs. Further discussion is provided under vegetation in Sections 5.9 and 7.2.9 and in the Vegetation Technical Report. Mitigation measures are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report Volume 6B Volume 6C

3.1.5.9 Wildlife and Wildlife Habitat

TABLE 3.1-11

INTERESTS OR CONCERNS RELATED TO WILDLIFE AND WILDLIFE HABITAT

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Effects from construction noise during nesting season Big Lake by Edmonton – important waterbody for birds	A suite of mitigation measures are proposed to reduce the potential effects of the Project on birds. For example, measures will be implemented to reduce the Project footprint to the extent feasible. Clearing and construction activities will be conducted outside the migratory bird restricted activity periods (RAP) set out by Environment Canada, to the extent practical. In the event clearing or construction activities are scheduled during the migratory bird RAP, Trans Mountain will work with Environment Canada to determine site-specific alternate mitigation. Mitigation options include pre-clearing, non-intrusive nest surveys, applying protective buffer around an active nest, or non-intrusive monitoring. Further discussion is provided under wildlife in Section 7.2.10. Mitigation measures for wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Wildlife Modelling and Species Accounts Technical Report Volume 6B
Protection of migratory bird patterns, decreasing food supply	Field surveys have been conducted and supplemental surveys will be completed in 2014 to confirm important breeding and fall staging waterbodies for migratory waterbirds. Appropriate mitigation (*e.g.*, scheduling to avoid periods when birds congregate, protective buffers) will be implemented to reduce the potential Project effects on migratory birds. The Project is unlikely to have a substantial effect on food supply for migratory birds. Nesting habitat was modelled for several bird indicators to provide an estimation of potential habitat change resulting from the Project. Models for nesting habitat are defined as the habitat used for nesting and caring for young, including foraging habitat for species that defend territories that include both nesting and foraging habitat (*e.g.*, most songbirds). Further discussion is provided under wildlife in Section 7.2.10. Mitigation measures for wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Wildlife Modelling and Species Accounts Technical Report Volume 6B
Effects on birds in forested areas	The potential effects of the Project and mitigation measures to reduce effects are discussed in Section 7.2.10 of Volume 5A. The results of habitat models completed for forest nesting birds provide an estimate of the anticipated Project effects on nesting habitat for various forest nesting birds and bird communities.	Volume 5A Section 7.2.10 Volume 5C Wildlife Modelling and Species Accounts Technical Report Volume 6A Volume 6B
Effects on birds and mammals from diminished air quality due to loss of trees during construction	Change in air quality from clearing of trees is unlikely to have a measurable effect on wildlife. Further discussion of air emissions associated with the Project is provided under air emissions in Section 7.2.4.	Volume 5A Section 7.2.4
Protection of wildlife habitat and migration	A suite of mitigation measures will be implemented to reduce the potential effects of the Project on wildlife habitat and movement patterns. Mitigation measures include alignment of the proposed route parallel to and contiguous with existing linear features, minimizing the Project footprint to the maximum extent feasible, scheduling activity to avoid periods when migratory birds congregate at important staging areas and limiting barriers to wildlife movement. Further discussion and additional mitigation is provided under wildlife in Section 7.2.10. Mitigation measures for wildlife are outlined in the Pipeline, Facilities, and Westridge Marine Terminal EPPs (Volumes 6B, 6C and 6D).	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6B Volume 6C Volume 6D

TABLE 3.1-11 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Potential for habitat fragmentation with linear construction across multiple watercourses	The three main components of habitat fragmentation are habitat loss, reduced habitat patch size and increased isolation of patches. Effects of habitat fragmentation will be reduced by alignment of the proposed route parallel to and contiguous with existing linear features, and minimizing the Project footprint to the maximum extent feasible. Specific measures are recommended for protection of riparian areas, including riparian buffers (*i.e.*, reduced footprint), minimum disturbance construction (*e.g.*, hand clearing, avoiding grading and grubbing) and reclamation. Further discussion is provided under wildlife in Section 7.2.10. Mitigation measures for wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6B
Disruption to birds and animals in Surrey Bend Park	Mitigation will be implemented to minimize disruption of wildlife and wildlife habitat in Surrey Bend Park. Alignment of the proposed route parallel to and contiguous with existing linear disturbances, and utilizing shared workspace to the extent practical, will reduce the Project footprint within the Park. Mitigation to reduce effects on habitat, limit barriers to movement, avoid attraction of wildlife to the work site, minimize sensory disturbance and protect site-specific habitat features of importance is discussed in Section 7.2.10 and the Pipeline EPP (Volume 6B). Coastal riparian small mammals were included as an indicator for the assessment of wildlife and wildlife habitat. Pacific water shrew was specifically addressed in the assessment. Mitigation to reduce potential Project effects on Pacific water shrew were developed to be consistent with provincial guidance, and include: establishing a 100 m buffer from any identified Pacific water shrew habitat during construction, to the extent feasible; replanting native vegetation (shrubs and trees) within 30 m of a stream or wetland identified as Pacific water shrew habitat to regenerate cleared vegetation; and placement of coarse woody debris over the right-of-way within 30 m of a stream or wetland identified as Pacific water shrew habitat. In the event that Pacific water shrews are identified at a stream or wetland crossed by the proposed route, a capture and release may be required to temporarily/permanently relocate individual shrews.	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6B

3.1.5.10 Species at Risk

TABLE 3.1-12

INTERESTS OR CONCERNS RELATED TO SPECIES AT RISK

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Potential effects to endangered species	Indicators selected to assess the effects of the Project include various species at risk. Mitigation to reduce the effects of the Project on species at risk is included in Sections 7.0 and 8.0. With application of the proposed mitigation and commitments to work with regulatory authorities to develop additional mitigation, where warranted, the residual effects of the Project and contribution of the Project to cumulative effects on species at risk are concluded to be not significant. Further discussion is provided under vegetation, wildlife and species at risk in Sections 7.2.9, 7.2.10 and 7.2.11. Mitigation measures for species at risk are outlined in the Pipeline, Facilities and Westridge Marine Terminal EPPs (Volumes 6B, 6C and 6D).	Volume 5A Sections 7.0, 7.2.9, 7.2.10, 7.2.11 and 8.0 Volume 5C Vegetation Technical Report Fisheries (Alberta) Technical Report Fisheries (British Columbia) Technical Report Wildlife Technical Report Marine Resources – Westridge Marine Terminal Technical Report Marine Birds – Westridge Marine Terminal Technical Report Volume 6B Volume 6C Volume 6D

3.1.5.11 Ecological Risk

TABLE 3.1-13

INTERESTS OR CONCERNS RELATED TO ECOLOGICAL RISK

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Protection of parks and ecologically sensitive areas	Project routing criteria include avoidance of environmentally sensitive areas, to the extent practical. Where sensitive areas cannot be practically avoided, alignment of the proposed route parallel to and contiguous with existing linear disturbances will minimize the Project footprint within sensitive areas, and mitigation will be implemented to reduce the Project's residual effects. The assessment of Project effects on parks and sensitive areas, including routing criteria and mitigation strategies to reduce the predicted effects, is included in Sections 4.0 and 7.0 of Volumes 5A and 5B. Mitigation measures are provided in the Pipeline and Facilities EPPs (Volumes 6B and 6C). Ecological risk related to large spills is discussed in Volume 7.	Volume 4A Volume 5A Sections 4.0 and 7.0 Volume 5B Sections 4.0 and 7.0 Volume 6B Volume 6C Volume 7

3.1.5.12 Consultation Activities with Federal and Provincial Authorities

Specific disciplines consulted with federal, provincial, regional and municipal authorities throughout the proposed pipeline corridor. For applicable biophysical elements, a summary table provides detailed information on the agency contacted, name and title of contact, method of contact, date of engagement, reason for engagement, key interests and concerns as well as any commitments or follow-up actions required.

TABLE 3.1-14

SUMMARY OF CONSULTATION ACTIVITIES RELATED TO GROUNDWATER QUANTITY AND QUALITY

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/ Follow-up Actions/Comments	Where Issue is Addressed in the Application
PROVINCIAL CONSULTATION – BRITISH COLUMBIA							
BC Ministry of Forest, Lands and Natural Resource Operations (BC MFLNRO)	Michele Lepitre, Regional Hydrogeologist, South Coast Region, BC MFLNRO	Email	November 11, 2012	Project Introduction Discuss review of Vedder River Fan Aquifer in Chilliwack concerns, Sumas Mountain spill in 2012.	Vedder River Fan Aquifer identified as highly vulnerable, MFLNRO aware of public concerns related to the aquifer. Sumas Mountain spill was of public concern, however, MFLNRO was not contacted in relation to any related groundwater issues.	None.	Volume 5A Sections 5.3.3 and 7.2.3 Volume 5C Groundwater Technical Report
BC Ministry of Environment (BC MOE)	Vicki Carmichael, Senior Hydrogeologist, Water Protection and Sustainability Branch Environmental Sustainability Division	Telephone	February 20, 2013	Project Introduction Request a teleconference/webex to allow the TMEP team to discuss the Project and obtain information for the groundwater review process	MOE is unable to comment on the process until the regulatory review process is initiated.	The TMEP is under the jurisdiction of the NEB.	N/A
STAKEHOLDER CONSULTATION – BRITISH COLUMBIA							
City of Chilliwack	David Blain		November 9, 2012	To introduce the Project and to identify water sources among other subjects.	Raised concerns about groundwater and the Vedder River Fan Aquifer, potential effects of an accident or malfunction on groundwater.	None.	Volume 5A Sections 5.3.3 and 7.2.3 Volume 5C Groundwater Technical Report

TABLE 3.1-14 Cont'd

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/ Follow-up Actions/Comments	Where Issue is Addressed in the Application
Community of Blue River	Hughes, P. Director of Environmental Services. Thompson-Nicola Regional District	Meeting	May 29, 2013	To introduce the Project and to identify water sources.	Two community drinking water system wells.	Confirm location of wells relative to proposed pipeline corridor.	N/A
Community of Vavenby	Hughes, P. Director of Environmental Services. Thompson-Nicola Regional District	Meeting (Clearwater)	June 5, 2013	To introduce the Project and to identify water sources.	North Thompson River – no wells.	None.	N/A
District of Clearwater	Madden, S. Services Coordinator. Thompson-Nicola Regional District	Meeting	June 5, 2013	To introduce the Project and to identify water sources.	Deep well that serves the fire department near proposed pipeline corridor.	Confirm location of well relative to proposed pipeline corridor.	N/A
City of Kamloops	Fretz, J. Sustainability and environmental Services Manager	Meeting	June 6, 2013	To introduce the Project and to identify water sources.	Campbell Creek community system and the Heffley private water utility which are both sourced from wells.	Confirm location of wells relative to proposed pipeline corridor.	N/A

None.	Information received from Spruce Grove office.	Volume 5A Section 7.2.7 Volume 5C Fisheries (Alberta) Technical Report
AESRD	Don Hildebrandt, Fisheries Technician	Email	November 19, 2013	Submission of fish and fish habitat data as required by provincial permitting. Inquiry on fish capture results and provision of presence information for Arctic grayling at Little Brule Creek.	None.	None.	Volume 5A Section 7.2.7 Volume 5C Fisheries (Alberta) Technical Report

TABLE 3.1-18

SUMMARY OF CONSULTATION ACTIVITIES RELATED TO FISH AND FISH HABITAT IN BRITISH COLUMBIA

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/ Follow-Up Actions/ Comments	Where Issue is Addressed in the Application
FEDERAL CONSULTATION							
DFO	Jennifer Simpson, Team Leader Brenda Andres, Environmental Assessment Analyst	Meeting	September 14, 2012	Project introduction. Outline methods and approach to fish and fish habitat investigations along the Project length. Brief review of regulatory changes.	No concerns with general methodology. Data will be collected as per provincial standards.	None.	N/A
DFO	Dave Pehl, Habitat Protection Officer, Oil and Gas Unit	Meeting	September 25, 2013	Project introduction. Outline methods and approach to fish and fish habitat investigations along the Project length. Brief review of regulatory changes.	No concerns with the general methodology. Need to ensure that compensation projects have high probability of success.	Engage DFO at the time of developing Fish Habitat Compensation. Ensure First Nation involvement in development and implementation.	Volume 5A Sections 5.7 and 7.2.7 Volume 5C Fisheries (British Columbia) Technical Report
PROVINCIAL CONSULTATION – BC							
Pacific Salmon Foundation	--	Meeting	October 2, 2013	To review overall strategy for compensation/offset.	Projects should be strategic to yield the maximum benefit.	Ensure Foundation is engaged on the development of compensation/offset plans.	Volume 5A Sections 5.7 and 7.2.7 Volume 5C Fisheries (British Columbia) Technical Report

TABLE 3.1-19

SUMMARY OF REGULATORY ACTIVITIES RELATED TO WETLAND LOSS AND ALTERATION

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/ Follow-up Actions/ Comments	Where Issue is Addressed in the Application
FEDERAL CONSULTATION							
Environment Canada	Andrew Robinson, Wildlife Biologist, BC	Meeting	December 6, 2011	Wetland evaluation methods were presented for discussion.	No concerns with methods were brought forward.	None.	N/A
Environment Canada	Harp Gill Andrew Robinson Paul Gregoire	Meeting	April 17, 2013	Wetland evaluation methods, study areas and indicators were presented for discussion.	Address alteration of wetland habitat function related to wildlife quantitatively.	None.	Volume 5A Sections 5.8 and 7.2.8 Volume 5C Wetland Evaluation Technical Report
PROVINCIAL CONSULTATION – ALBERTA							
AESRD	Muhammad Aziz, Team Lead, Water Team, Spruce Grove Central Region – Environmental Operations Rick Nutbrown, Water Administration Engineer, Spruce Grove Central Region – Environmental Operations	Meeting	June 21, 2013	Provide a Project overview and discussion of: Local Study Area (LSA) and Regional Study Area (RSA) boundaries, cumulative effects approach, survey methodologies and mitigation recommendations.	No concerns were brought forward.	None.	N/A
MUNICIPAL CONSULTATION – ALBERTA							
Strathcona County	Jocelyn Thrasher-Haug, Manager, Environmental and Open Space Planning	Email	July 29, 2013 August 6, 2013	Clarifying what regulatory requirements need to be met in regards to wetland disturbance as a result of Project construction.	Continued follow-up with Strathcona County in progress.	Further consultation will continue as required.	Volume 5A Sections 5.8 and 7.2.8 Volume 5C Wetland Evaluation Technical Report

TABLE 3.1-20

SUMMARY OF CONSULTATION ACTIVITIES RELATED TO VEGETATION

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
FEDERAL CONSULTATION							
Environment Canada – Canadian Wildlife Service (CWS)	Paul Gregoire, Senior Environmental Assessment Officer	Meeting (see below) Mr. Greogoire via Telephone	April 17, 2013	Review work plans for the wildlife, vegetation, wetland and marine components for the Project. Preliminary KIs and field survey methods were introduced and discussed.	--	April 19, 2013: the list of preliminary wildlife KIs is sent to Environment Canada for further review and comment. April 21, 2013: a copy of the meeting minutes is sent to Environment Canada for review. May 21, 2013: Environment Canada reviews the meeting minutes and provides comments and questions. Further comment is also provided on the list of preliminary wildlife indicators. May 22, 2013: Environment Canada provides additional comments on the width of the Wetlands and Vegetation LSAs and suggests that the wetlands functional assessment include surveys to identify the presence and distribution of migratory birds and species at risk in relation to specific potentially affected wetlands and associated riparian areas. August 25, 2013: a copy of the revised meeting minutes is provided to Environment Canada that responds to their questions from May 21 and 22, 2013. The approach involving spring and summer surveys by regional vegetation specialists was accepted.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report

TABLE 3.1-20 Cont'd

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
Environment Canada – CWS	Harp Gill, Senior Environmental Assessment Officer Jennifer Wilson, Special Projects Officer Andrew Robinson, Senior Environmental Assessment Officer Rene McKibbin, Environmental Assessment Officer (Advisor to Environment Canada with Gebauer and Associates) Paul Gregoire, Senior Environmental Assessment Officer	Meeting Mr. Greogoire via Telephone	April 17, 2013	Project introduction. Review of work plans including terrestrial ecosystem mapping (TEM) Survey methodologies. Review of the results of consultation with provincial ecologists.	Environment Canada asked how much new right-of-way there would be, how all information could be collected in 1 year of field work and if there was any existing TEM that could be used. Environment Canada asked why all field work being conducted, especially wetlands, could not be fed back into TEM. Environment Canada asked what data sources would be used for TEM. Environment Canada accepted TERA's use of Survey Intensity Level 5 and acknowledged that some compromises had to be made given the scope of the Project, but emphasized that the approach needs to be justified and defensible.	TERA offered additional details about timelines and plans for supplementary TEM mapping and field plots in fall 2013 and 2014. TERA offered additional details about TEM data sources.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Environment Canada – CWS	Jan Kirkby, Landscape Ecologist	Email	November 7, 2013	Project introduction. TEM Survey methodologies.	No response to date.	None.	N/A
PROVINCIAL CONSULTATION – ALBERTA							
City of Edmonton	Daniel Laubhann, city's weed group	Email	April 17 to 22, 2013	Project Introduction. Weeds of concern. Preferred invasive species control practices.	Weeds of concern list and city's *Integrated Pest Management Policy* provided. Concern with spread of weeds from Parkland County and Yellowhead highway. Request for detailed map of Project area within city.	More detailed map was provided on October 8, 2013.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Strathcona County	Joel Gould, Agricultural Fieldman Diana Laviolette Brown, Assistant Agricultural Fieldman Lori Mills, Energy Exploration Liaison	Email	September 30, 2013	Project Introduction. Weeds of concern. Preferred invasive species control practices.	Provided information on a clubroot positive location and weeds of concern along the Project. Additional comments possible following confirmation of route.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report

TABLE 3.1-20 Cont'd

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
Parkland County	James Leskiw, Supervisor, Agricultural Agronomics	Email, Telephone	April 17 to 22, 2013	Project Introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Provided list of clubroot positive fields. Recommended the Clubroot Management Plan be followed. Concerns regarding spread and introduction of Noxious and Prohibited Noxious weeds. Request for detailed map of Project area within county.	More detailed map was provided on October 8, 2013.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
City of Spruce Grove	Info@sprucegrove.org	Email Telephone	April 17, 2013 – No response was received Follow-up email and call on September 30, 2013	Project introduction. Weeds of concern. Preferred invasive species control practices.	No response.	On September 30, 2013, the email mailbox was full and message was undeliverable. A call was placed to the city. No one responded and there was no voicemail.	N/A
Town of Stony Plain	Rudy Zacharias, Communications Coordinator	Email	April 17 to 18, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Provided list of weeds of concern. Inquired about equipment decontamination procedures, weed control/eradication plans and regular weed inspection plans for right-of-way.	May 6, 2013 provided answers to questions regarding mitigation for decontamination of equipment, weed management and monitoring.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Village of Wabamun	Trevor Anderson, Economic Development Officer/Marketing Coordinator	Email	April 17 to 18, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Have no specific concerns regarding weeds or crop diseases.	None.	N/A
Wabamun Lake Provincial Park	Matthew Wheatley, Conservation Biologist, Provincial Parks Division	Email	October 25, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Awaiting response.	None.	N/A
Yellowhead County	Sonja Pichette, Agricultural Services Coordinator	Email	April 17 to 24, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Provided a list of weeds of concern and the general location of clubroot positive fields which are all considerably distant from the proposed Project.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Alberta Conservation Information Management System (ACIMS)	Lorna Allen	Email	September 13, 2013	Rare ecological community confirmation.	--	None.	N/A

TABLE 3.1-20 Cont'd

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
PROVINCIAL CONSULTATION – BRITISH COLUMBIA							
Regional District of Fraser Fort George	Jim Martin, Chief Administrative Officer	Email	April 17 to 22, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Referred to Andrea Eastham of the NWIPC.	Follow-up email was sent to Andrea Eastham on September 30, 2013.	N/A
Northwest Invasive Plant Council (NWIPC)	Andrea Eastham, Program Manager	Email	April 17, 2013 Follow-up email was sent on September 30, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	On October 3, 2013, a list of sites treated for invasive plant infestations was provided. Species of concern were identified as well as issues from to the TMX Anchor Loop project that they wish to avoid with the current Project. Concerns include spread and introduction of infestations. Requested maintaining clean storage sites and clean vehicles and equipment (with inspections and reporting), treating infestations prior to construction, comply with no herbicide and bio-release sites and submitting invasive species data to the provincial database. Expressed desire to participate in the invasive management component of the Project.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
TNRD	Peter Hughes, Director of Environmental Services Jamie Vieira, Operations Supervisor, Environmental Health Services	Email	April 17, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	On June 28, 2013, the Pest Management Plan was provided. Reference was made to provincial Noxious weeds, regionally-listed weeds and the *Invasive Plant Regulation* under the *Forest and Range Practices Act (FRPA)* as well as to treatment methods. It was recommended to contact David Ralph of the Invasive Plant Program at the BC MFLNRO as well as Jo-Ann Fox, the Manager of the Southern Interior Weed Management Committee (SIWMC).	On October 9, 2013, David Ralph was emailed for input. On April 18, 2013 Jo-Anne Fox was emailed for input.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
BC MFLNRO	David Ralph, Invasive Plant Program	Email	October 9, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Awaiting response.	Follow-up again in November.	N/A

TABLE 3.1-20 Cont'd

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
SIWMC	Jo-Anne Fox, Coordinator	Email	April 18, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Provided the Thompson-Nicola Strategic Plan 2013 identifying species of concern and management methods.	None.	N/A
FVRD	Stacey Barker, Manager of Environmental Services	Email	April 17, 2013 Follow-up email was sent on October 1, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	On October 2, 2013, a list of weed species of concern and a website with location, distribution and treatment information was proposed. Recommended conducting field surveys for weeds immediately prior to construction.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Fraser Valley Invasive Plant Council (FVIPC)	Jeanne Hughes, Coordinator	Email	April 17, 2013 Follow-up email was sent on October 1, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Awaiting response.	None.	N/A
Greater Vancouver Regional District (GVRD)	Alison Evely, Natural Resource Management Specialist Heather McNell, Regional Planning Division Manager	Email	April 17, 2013 Follow-up email was sent on October 1, 2013	Project Introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	On October 3, 2013, the Integrated Pest Management Plan identifying weeds of concern and treatment approaches was provided (Evely 2012). Reference was also made to the Invasive Species Council of Metro Vancouver (ISCMV) website for information.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
ISCMV	Jennifer Grenz, Manager Tasha Murray, Administration and Education Manager	Email	April 17, 2013 Follow-up email was sent on October 1, 2013	Project introduction. Weeds and crop diseases of concern. Preferred invasive species and crop disease control practices.	Awaiting response.	None.	N/A
BC Conservation Data Centre (CDC)	cdcdata@gov.bc.ca	Email	April 18, 2013	Request resources regarding rare ecological communities for which there is little or no information in Land Management Handbooks.	Provided some additional links to information sources.	None.	N/A
BC CDC	Jenifer Penny	Email Telephone	June 17, 2013 to present	Information on the status of unranked liverworts.	Provided preliminary information on the status of unranked liverworts in BC.	Requested that high level information on all liverwort occurrences (not just rare species) be submitted to the BC CDC to assist in ranking.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Government of BC	Corey Erwin, Vegetation Ecologist	Email	July 27, 2012	Project introduction. TEM Survey methodologies.	No response to date.	None.	N/A

TABLE 3.1-20 Cont'd

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
Thompson-Okanagan Region, Government of BC	Michael Ryan, Research Ecologist	Telephone	August 28 and September 12, 2012	Project introduction. TEM Survey methodologies.	Michael Ryan invited TERA to follow-up via email.	See below.	N/A
		Email	October 26 to November 15, 2012	Project introduction. TEM Survey methodologies.	Michael Ryan advised Survey Intensity Level 4 and requested additional details about existing TEM relevant to the Project. Michael Ryan offered contact information for other regional ecologists. Michael Ryan advised how to correlate the 2005 draft Biogeoclimatic Ecosystem Classification (BEC) for the Thompson-Okanagan Region with the current Red and Blue-listed rare ecological communities.	TERA offered additional detail about rare plant and rare ecological community surveys as justification for Survey Intensity Level 5. TERA offered additional details about existing TEM. TERA requested further comment on Survey Intensity Level 5 with regards to additional. No further comment has been received.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
		Email	February 22 to April 15, 2013	Land Management Handbook advice.	TERA requested input on which Land Management Handbooks to use to classify vegetation communities in the MSmw1 and ESSFmw1. Michael Ryan provided draft Land Management Handbooks by Lloyd *et al.* (2005) and a cross walk table between the site series in the ESSFmw1 and the ESSFmw.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Omineca and NE Region, Government of BC	Bruce Rogers, Research Ecologist	Email	October 29 to November 23, 2012	Project introduction. TEM Survey methodologies.	Bruce Rogers advised Survey Intensity Level 4. Bruce Rogers requested PDF of the proposed pipeline corridor showing the ESSFmm1.	TERA offered additional detail about rare plant and rare ecological community surveys as justification for Survey Intensity Level 5. TERA offered additional details about existing TEM. TERA sent requested PDF. TERA requested further comment on Survey Intensity Level 5 with the additional surveys. No further comment has been received.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Coastal Region, Government of BC	Dr. Sari Sanders, Research Ecologist	Email	October 29 to November 15, 2012	Project introduction. TEM Survey methodologies.	No response to date.	None.	N/A
Provincial Lichen Expert	Trevor Goward	Meeting, Telephone, Email	March to November 2013	Lichen specimen identification; consultation regarding lichen species rarity.	Provided identifications and expert experience regarding species that are not ranked by the BC CDC and those that are tracked but are not considered provincially rare or requiring mitigation.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report

TABLE 3.1-20 Cont'd

Stakeholder Group/Agency Name	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement	Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
Provincial Lichen Expert	Curtis Bjork	Email	October 2013	Consultation regarding lichen and bryophyte species rarity.	Provided expert experience regarding species that are not ranked by the BC CDC and those that are tracked but are not considered provincially rare or requiring mitigation.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Provincial Bryophyte Expert	Terry McIntosh	Email	March to October 2013	Coordinating field survey; bryophyte specimen confirmation.	Conducted field surveys; provided confirmation of *Schistidium* moss specimens.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Provincial Bryophyte Expert	Rene Belland	Email	October to November 2013	Consultation regarding bryophyte species rarity.	Provided expert experience regarding tracked species.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Provincial Bryophyte Expert	Peter Whitehead	Meeting, Telephone, Email	March to November 2013	Coordinating field survey; consultation regarding bryophyte species rarity.	Conducted field surveys; provided expert experience regarding species that are tracked but are not considered provincially rare or requiring mitigation.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Provincial Bryophyte Expert	Sandra Davis	Meeting, Telephone, Email	March to November 2013	Bryophyte specimen identification; consultation regarding bryophyte species rarity.	Provided identifications and expert experience regarding species that are not ranked by the BC CDC and those that are tracked but are not considered provincially rare or requiring mitigation.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report
Provincial Rare Plant Expert	Matt Fairbarns	Email	June 18, 2013 to present	Input on survey timing, habitats and whether or not preferred habitat is on the proposed right-of-way for the species in the rare plant potential tables.	Provided us with tracked changes in the potential tables on July 3 and 4, 2013.	None.	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report

Wildlife and Wildlife Habitat

TABLE 3.1-21

SUMMARY OF CONSULTATION ACTIVITIES RELATED TO WILDLIFE AND WILDLIFE HABITAT

Stakeholder Group/Agency	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement and Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
FEDERAL CONSULTATION						
Environment Canada – CWS	Harp Gill, Senior Environmental Assessment Officer, Pacific and Yukon Region	Email	March 15, 2013 March 25, 2013 March 27, 2013	Provide shapefiles of proposed pipeline corridor (March 15 and 27). Send draft Work Plans and preliminary indicators for wildlife, vegetation and wetland components for the Project (March 25) prior to meeting on April 17, 2013.	None.	N/A
Environment Canada	Harp Gill, Senior Environmental Assessment Officer, Pacific and Yukon Region, CWS Jennifer Wilson, Special Projects Officer, Pacific and Yukon Region, CWS Andrew Robinson, Senior Environmental Assessment Officer, Pacific and Yukon Region, CWS Rene McKibbin, Environmental Assessment Officer, Pacific and Yukon Region, CWS Martin Gebauer, Advisor to Environment Canada, Pacific and Yukon Region Paul Gregoire, A/Head Program & Planning Coordination, Prairie & Northern Region, CWS (via conference call)	Meeting in Delta, BC	April 17, 2013	Review work plans for the wildlife, vegetation, wetland and marine wildlife components for the Project. Preliminary indicators and field survey methods were introduced and discussed.	April 19, 2013: the list of preliminary wildlife indicators is sent to Environment Canada for further review and comment. April 21, 2013: a copy of the Meeting Minutes is and sent to Environment Canada for review. May 21, 2013: Environment Canada reviews the Meeting Minutes and provides comments and questions. Further comment is also provided on the list of preliminary wildlife indicators. May 22, 2013: Environment Canada provides additional comments on the width of the Wetlands/Vegetation LSA, and that the wetlands functional assessment includes surveys to identify the presence and distribution of migratory birds and species at risk in relation to specific potentially affected wetlands and associated riparian areas. August 25, 2013: a copy of the revised Meeting Minutes is provided to Environment Canada that responds to their questions provided in the Meeting Minutes (May 21, 2013), as well as the additional comment provided on May 22, 2013 are provided to Environment Canada.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
Environment Canada – CWS	Paul Gregoire, A/Head Program & Planning Coordination, Prairie & Northern Region	Meeting in Edmonton, Alberta	June 7, 2013	Review proposed corridor, preliminary wildlife indicators, and wildlife field program.	None.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report

TABLE 3.2-21 Cont'd

Stakeholder Group/Agency	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement and Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
Environment Canada – CWS	Harp Gill, Senior Environmental Assessment Officer, Pacific and Yukon Region	E-mail	August 1, 2013	Request information on candidate critical wildlife habitat that may be encountered along the proposed pipeline corridor, including pacific water shrew habitat mentioned during the Surrey Community Interest Workshop.	September 9, 2013: A data-sharing agreement is signed and Environment Canada provides hard-copy maps of candidate critical habitat for: pacific water shrew; Williamson's sapsucker; Oregon forest snail; Toothcup; coastal giant salamander; barn owl (western population); Lewis's woodpecker; American badger; Townsend's mole; and whitebark pine.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
Environment Canada – CWS	Harp Gill, Senior Environmental Assessment Officer, Pacific and Yukon Region	E-mail	August 25, 2013	Provide updated Meeting Minutes from April 17, 2013 meeting. Send for review the following: updated wildlife indicator list, information on the LSA and RSA boundaries; send information and maps showing proposed grizzly bear and caribou RSA boundaries. Request if the proposed pipeline corridor encounters any known habitat sites for band-tailed pigeon, and if there are any other conflicts with important habitat (not publically available) with the proposed pipeline corridor. Ask for clarification that the Pacific and Yukon Region is the primary contact for the Project and that all correspondence will be provided to P. Gregoire (Prairie and Northern Region, Edmonton).	September 4, 2013: Environment Canada responds that the Pacific and Yukon Region will be the primary contact and correspondence will be forwarded to P. Gregoire (Edmonton). September 19, 2013: Environment Canada responds they do not have any comments on the study area boundaries. September 30, 2013: Environment Canada provides a response related to band-tailed pigeon and notes that they do not have specific mapping layers for band-tailed pigeon, however, they may be encountered throughout the Coast Range at low and mid-elevations up to the central coast. Environment Canada recommends that they be considered as a sensitive species for the coastal portion of the Project, as this area is within the species range and contains suitable habitat.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
Environment Canada – CWS	Jennifer Wilson, Special Projects Officer, Pacific and Yukon Region	Email	September 30, 2013	Environment Canada provides additional feedback on wildlife indicators.	None.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
PROVINCIAL CONSULTATION - ALBERTA						
AESRD (Edmonton)	Dave Hobson, Wildlife Biologist	Email	August 26, 2013	Provide a summary of the protective notations (PNTs) and trumpeter swan lakes that are encountered by the proposed pipeline corridor and request feedback related to mitigation. Provide information on the LSA and RSA study area boundaries, including the grizzly bear RSA for review.	September 6, 2013: AESRD notes that the proposed pipeline corridor is generally close to Highway 16 and the primary concern for grizzly bears relates to the creation of new access. Feedback was provided on trumpeter swan lakes and the PNTs within the area covered by the Edson office.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report

TABLE 3.2-21 Cont'd

Stakeholder Group/Agency	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement and Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
AESRD (Upper Athabasca Region, Hinton)	Jeff Kneteman, Senior Wildlife Biologist	Email	September 11, 2013	Provide an introduction to the Project and a summary of the PNTs that are encountered by the proposed pipeline corridor and request feedback related to mitigation. Request feedback on potential long-toed salamander breeding pond near the existing Hinton pump station. Provide information on the LSA and RSA study area boundaries, including the grizzly bear RSA for review.	September 15, 2013: AESRD responds that primary recommendation is to prioritize the conservation and immediate placement of topsoil, including protecting native species propagules and restoration of the native plant community composition and structure as quickly as possible. Winter construction is the best timing with respect to minimizing risk to salamanders. It is preferred that an additional pipeline not be located nearest the breeding pond (*i.e.*, on the pond side).	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
PROVINCIAL CONSULTATION – BRITISH COLUMBIA						
BC MFLNRO (Fraser-Fort George District, Prince George)	Brady Nelless, A / Landbase Stewardship Section Head	Email	August 10, 2012	Provide introduction to the Project and a preliminary list of wildlife indicators and background information on indicator selection. Request a meeting to discuss the following: • habitats of concern in proximity to the proposed route in your region (*e.g.,* protected areas, sensitive habitat features, etc.); • a review of preliminary wildlife indicators to be used in the environmental assessment; • available data that would be useful in supporting a thorough examination of potential effects on wildlife in the region; • recommended field protocols, particularly any that may differ from the Resources Inventory Standards Committee (RISC) standard protocols; • recent habitat models that have been developed and validated for species of interest in the region; • recommended individuals or groups for further consultation; and • any other concerns or questions.	August 20, 2012: MFLNRO responds that Kevin Hoekstra will by the Regional contact for this Project.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
BC MFLNRO (Omineca Region, Prince George)	Kevin Hoekstra, Ecosystem Biologist	Email	August 28, 2012 May 23, 2013 July 31, 2013 October 16, 2013	Provide shape-file of the proposed pipeline corridor as it is updated.	---	N/A
		Telephone	September 7, 2012	Project Introduction and routing review. BC MFLNRO noted that the proposed corridor is located in valley and will parallel other linear corridors and would like to see the natural buffer that is between the existing highway and existing TMPL right-of-way maintained. The pipeline does not cross known wildlife features, WHA or UWR, however, there are elk and white-tail deer in the area. Reclamation should avoid using seed that is palatable to wildlife to prevent an increased chance of wildlife mortality.	September 7, 2012: Will contact again to discuss the Project in more detail (indicator species, study boundaries and recommended surveys).	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report

TABLE 3.2-21 Cont'd

Stakeholder Group/Agency	Name and Title of Contact	Method of Contact	Date of Consultation Activity	Reason For Engagement and Issues/Concerns	Commitments/Follow-up Actions/Comments	Where Issue is Addressed in the Application
BC MFLNRO (Omineca Region, Prince George) (cont'd)	See above	Email	January 8, 2013	Send preliminary winter transect locations and proposed field survey methods for review.	January 11, 2013: MFLNRO recommends a winter transect near the interface between Cranberry Marsh and the crown land to the west, and notes the other locations are suitable including a transect located in the riparian area of Camp Creek.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
		Email	March 11, 2013	Request information on existing models for mountain caribou and concerns related to routing within caribou range.	March 12, 2013: BC MFLNRO responds that the only habitat modelling is related to the caribou recovery plan. Within the Omineca Region, the proposed pipeline corridor parallels the existing TMPL right-of-way and is outside the known caribou range.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
		E-mail	August 16, 2013	Provide a description of RSA and LSA boundaries; maps showing proposed grizzly bear and caribou RSA; and an updated wildlife indicator list for review and feedback.	---	N/A
		Telephone	October 24, 2013	Discuss information provided on August 16, 2013. No concerns associated with the proposed study area boundaries and indicator list.	October 24, 2013: provide preliminary moose model (Draft Species Account/Model Assumptions/TEM ratings) for review.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report
BC MFLNRO (Thompson-Nicola District, Kamloops)	John Surgenor, Wildlife Biologist Robyn Reudink, Ecosystem Biologist	Email	July 4, 2012	Provide introduction to the Project and a preliminary list of wildlife indicators and background information on indicator selection. Request a meeting to discuss the following: • habitats of concern in proximity to the proposed route in your region (*e.g.,* protected areas, sensitive habitat features, etc.); • a review of preliminary wildlife indicators to be used in the environmental assessment; • available data that would be useful in supporting a thorough examination of potential effects on wildlife in the region; • recommended field protocols, particularly any that may differ from the RISC standard protocols; • recent habitat models that have been developed and validated for species of interest in the region; • recommended individuals or groups for further consultation; and • any other concerns or questions.	August 14, 2012: MFLNRO responds that Robyn Reudink will by the Regional contact for this Project.	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report

3.2 Aboriginal Engagement

Since April 2012, Trans Mountain has engaged with Aboriginal communities that might have an interest in the Project or have Aboriginal interests potentially affected by the Project, based on the proximity of their community and their assertion of traditional and cultural use of the land along the proposed pipeline corridor to maintain a traditional lifestyle. Trans Mountain respects the Aboriginal and treaty rights, unique culture, diversity, languages and traditions of Aboriginal people. Trans Mountain acknowledges the importance of teaching, the significance of culture and language and the considerable traditional knowledge that has been passed on for generations and as such is committed to continued listening, learning and working with Aboriginal people to ensure that knowledge and advice is considered and incorporated in the Project. The Aboriginal Engagement Program is based on mutual respect, timeliness, accountability and transparency in order to build positive and productive relationships for the long-term.

This subsection provides information on the Aboriginal Engagement Program for the Project and describes how the results of Project engagement activities relating to the ESA were gathered as well as how these results have been incorporated into the application. The Aboriginal Engagement Program was developed in accordance with the KMC Aboriginal Policy and Volume 3B provides detailed information on Trans Mountain's approach to the Aboriginal Engagement Program as well as detailed information on the Trans Mountain vision and the principles and goals of the engagement program and engagement activity to date.

For purposes of this application, the engagement activities conducted to date are reported up to November 30, 2013. The results of ongoing engagement efforts will be reported in supplemental filings.

3.2.1 Design of Aboriginal Engagement Program

3.2.1.1 Identification of Aboriginal Communities and Aboriginal Groups

Beginning in 2012 Trans Mountain worked in collaboration with the federal government and provincial ministries to identify Aboriginal communities and Aboriginal groups for engagement. Aboriginal communities in BC were identified as those within a 10 km buffer of the corridor. Of these, there are Aboriginal communities who are negotiating treaties within the BC Treaty Commission process and those that are not currently engaged in the BC treaty process. Aboriginal communities in Alberta were identified as those within a 100 km buffer of the corridor.

Trans Mountain also contacted each of the provincial government ministries (the BC Ministry of Aboriginal Relations and Reconciliation and the Alberta Ministry of Aboriginal Affairs) and received guidance on the development of engagement lists for the Project. In addition to engagement with the federal and provincial ministries, further engagement took place in early 2012 with representatives from the Major Projects Management Office (MPMO), NEB, and BC OGC regarding communities and groups to include in the Aboriginal Engagement Program.

The result was a comprehensive list of 103 Aboriginal communities with traditional territories located within 10 km of the corridor in BC and 100 km in Alberta, and two non-land based BC Métis groups included in the engagement list: the BC Métis Federation; and the Métis Nation of BC. In total, Trans Mountain is engaged with 105 Aboriginal communities and Aboriginal groups. Geographically, in Alberta and BC there are substantial areas of shared territory with the 103 communities engaged.

Details regarding the identification of communities that might have an interest in the Project or having Aboriginal interests potentially affected by the Project are provided in Volume 3B.

3.2.1.2 Aboriginal Communities and Aboriginal Groups Engaged

The following is a list of the 103 Aboriginal communities and two non-land based BC Métis groups in proximity to the pipeline corridor and marine corridor that was assessed pursuant to the NEB's instruction in their List of Issues, issued July 29, 2013, that might have an interest in the Project or have Aboriginal interests potentially affected by the Project:

Aboriginal Communities Located in the Edmonton to Alberta/British Columbia Border Region

Alexander First Nation	Louis Bull Tribe	Samson Cree Nation
Alexis Nakota Sioux Nation	Métis Regional Council Zone IV of the Métis Nation of Alberta (Region 4)	Sturgeon Lake Cree Nation
Aseniwuche Winewak Nation	Montana First Nation	Sunchild First Nation
Enoch Cree Nation	Nakcowinewak Nation of Canada	
ErmineskinCree Nation	O'Chiese First Nation	
Foothills Ojibway First Nation	Paul First Nation	
Horse Lake First Nation	Saddle Lake Cree Nation	

Aboriginal Communities Located in the Alberta/British Columbia Border to Kamloops Region

Adams Lake Indian Band	Lhtako Dene Nation	Splatsin First Nation
Aseniwuche Winewak Nation	Neskonlith Indian Band	Tk'emlúps te Secwepemc
Ashcroft Indian Band	Oregon Jack Creek Band	Toosey Indian Band
Canim Lake Band (Tsq'escenemc Nation)	Shuswap Indian Band	Whispering Pines (Clinton Indian Band)
Little Shuswap Indian Band	Simpcw First Nation	Xat'sull First Nation (Soda Creek)
Lheidli T'enneh	Skeetchestn First Nation	

Aboriginal Communities Located in the Kamloops to Hope Region

Boothroyd Band	Lower Similkameen Indian Band	Siska Indian Band
Boston Bar Band	Lytton First Nation	Skuppah Indian Band
Coldwater Indian Band	Nicomen Indian Band	Spuzzum First Nation
Cook's Ferry Indian Band	Nooaitch Indian Band	St'uxwtews (Bonaparte Indian Band)
Kanaka Bar	Penticton Indian Band	Upper Nicola Indian Band
Lower Nicola Indian Band	Shackan Indian Band	Upper Similkameen Indian Band

Aboriginal Communities Located in the Hope to Burnaby Terminal/Burrard Inlet Region

Aitchelitz First Nation	Popkum First Nation	Squamish First Nation
Chawathil First Nation	Qayqayt First Nation	Squiala First Nation
Cheam First Nation	Scowlitz First Nation	Sts'ailes Band (Chehalis Indian Band)
Katzie First Nation	Seabird Island Band	Sumas First Nation
Kwantlen First Nation	Semiahmoo First Nation	Tsawwassen First Nation
Kwaw-kwaw-aplit First Nation	Shxw'ow'hamel First Nation	Tsleil-Waututh Nation
Kwikwetlem First Nation	Shxwha:y Village	Tzeachten First Nation
Leq'á:mel First Nation	Skawahlook First Nation	Union Bar First Nations
Matsqui First Nation	Skowkale First Nation	Yakweakwioose First Nation
Musqueam First Nation	Skwah First Nation	Yale First nation
Peters Indian Band	Soowahlie First Nation	

Aboriginal Communities Located in the Marine Corridor

Cowichan Tribes	Pacheedaht First Nation	Songhees Nation
Esquimalt Nation	Pauquachin First Nation	Stz'uminus First Nation (Chemainus)
Halalt First Nation	Pacheedaht First Nation	T'Sou-ke First Nation
Hwlitsum First Nation	Scia'new Indian Band (Beecher Bay)	Tsartlip First Nation
Lake Cowichan First Nation	Sechelt Indian Band	Twawout First Nation
Lyackson First Nation	Snaw-Naw-As (Nanoose)	Tseycum First Nation
Malahat First Nation	Snuneymuxw First Nation	Stz'uminus First Nation (Chemainus)

Aboriginal Groups – Non-Boundary Specific

BC Métis Federation
Métis Nation of BC

3.2.1.3 Associations, Councils and Tribes

Trans Mountain has also engaged with multiple Aboriginal associations, councils, and tribes of which many of the Aboriginal communities listed in Section 3.2.1.3 are members. Additional details are provided in Volume 3B.

Cowichan Nation Alliance

The Cowichan Nation Alliance is an organization that was identified by Trans Mountain as an entity that might have an interest in the Project or having Aboriginal interests potentially affected by the Project. Made up of eight member communities, for the purposes of the Project, Trans Mountain is engaging with the following member communities who have indicated an interest in the Project:

- Cowichan Tribes;
- Halalt First Nation;
- Hwlitsum First Nation;
- Penelakut Tribe; and
- Stz'uminus First Nation.

Trans Mountain continues to engage with individual member communities and the Cowichan Nation Alliance to further enhance the Aboriginal Engagement Program.

Okanagan Nation Alliance

The Okanagan Nation Alliance is an organization that was identified by Trans Mountain as an entity that might have an interest in the Project or having Aboriginal interests potentially affected by the Project. Made up of eight member communities, for the purposes of the Project, Trans Mountain is engaged with the following four member communities who have indicated an interest in the Project:

- Lower Similkameen Indian Band;
- Penticton Indian Band;
- Upper Nicola Band; and
- Upper Similkameen Indian Band.

Trans Mountain continues to engage with the individual member communities and the Okanagan Nation Alliance to further enhance the Aboriginal Engagement Program.

Nicola Tribal Association

The Nicola Tribal Association is an organization that was identified by Trans Mountain as an entity that might have an interest in the Project or having Aboriginal interests potentially affected by the Project. Made up of seven member nations, for the purposes of the Project, Trans Mountain is engaged with the following Nicola Tribal Association member communities who have indicated an interest in the Project:

- Nicomen Indian Band;
- Nooaitch Indian Band; and
- Shacken Indian Band.

Trans Mountain continues to engage with the individual member communities and the Nicola Tribal Association to further enhance the Aboriginal Engagement Program.

Tk'emlúp Te Secwépemc

Tk'emlúp Te Secwépemc is an organization that was identified by Trans Mountain as an entity that might have an interest in the Project or having Aboriginal interests potentially affected by the Project.

As an administrative body working with communities with shared territories, for the purposes of the Project, Trans Mountain is engaged with the following Stkemlupsemc Te Secwepemc member communities who have indicated an interest in the Project:

- Skeetchestn First Nation; and
- Tk'emlúp Te Secwépemc.

Trans Mountain continues to engage with the individual member communities and the Tk'emlúp Te Secwépemc to further enhance the Aboriginal Engagement Program.

Ts'elxweyeqw Tribe Management Limited

Ts'elxweyeqw Tribe Management Limited is an organization that was identified by Trans Mountain as an entity that might have an interest in the Project or having Aboriginal interests potentially affected by the Project. Ts'elxweyeqw Tribe Management Limited is comprised of the following communities (all of which are engaged with the Project):

- Aitchelitz First Nation;
- Shxwha:y Village;
- Skowkale First Nation;
- Soowahlie Indian Band;
- Squiala First Nation;
- Tzeachten First Nation; and
- Yakweakwioose First Nation.

For the purposes of a Capacity Funding Agreement, the following Aboriginal communities are engaged with Ts'elxweyeqe Tribe:

- Kwaw-kwaw-apilt First Nation; and
- Shwah First Nation.

Additionally, for the purposes of an Integrated Cultural Assessment, the following two Aboriginal communities are engaged with the Project:

- Cheam First Nation; and
- Sumas First Nation.

Trans Mountain continues to engage with the individual member communities and Ts'elxweyeqw Tribe Management Limited to further enhance the Aboriginal Engagement Program.

3.2.1.4 Engagement Method

The Aboriginal Engagement Program uses a comprehensive Aboriginal engagement process led by experienced engagement advisors in Alberta and BC, working with a group of professionals who are specialized in the areas of Aboriginal relations, law, economic development, education, training, employment and procurement. Trans Mountain's engagement process for the Project is flexible, allowing each community and group to engage in meaningful dialogue in the manner they choose and in a way that meets their objectives and values.

In May 2012, the Trans Mountain Aboriginal engagement team was created and Aboriginal engagement team field advisors were assigned to each of the groups based on their knowledge and experience. Each advisor is a professional experienced in engagement.

The Aboriginal Engagement Program focuses on:

- enhancing trusting and respectful relationships;
- sharing Project information – Project scope, routing options, safety and emergency response, scheduling and environmental field study components;
- negotiating group and community-specific protocols, capacity agreements, Letters of Understanding (LOUs) and Mutual Benefit Agreements (MBAs), as appropriate;
- facilitating Traditional Land Use (TLU) studies, socio-economic interviews and Traditional Ecological Knowledge (TEK) collection;
- identifying potential effects and addressing concerns;
- discussing the adequacy of planned mitigation and opportunities; and
- identifying education, training, employment and procurement opportunities.

3.2.1.5 Comprehensive Aboriginal Engagement Process

Acting as a framework for the engagement process, the following activities provide guidance to ensure a comprehensive and consistent process in working with each of the communities identified by Trans Mountain.

As outlined in Volume 3B, each community has the opportunity to engage with Trans Mountain in the manner they choose, depending on Project interests and potential effects:

- Project announcement;
- initial contact with Aboriginal community or Aboriginal group;
- meetings with Chief and Council, and meetings with staff;
- negotiate and execute confidential LOU/capacity agreement;
- host community information session(s);
- conduct TLU studies and socio-economic interviews;
- identify interests and concerns;
- identify mitigation options;
- provide additional capacity funding, if required; and
- negotiate and execute confidential mutual benefits agreement.

In December 2013, at the time of filing, Trans Mountain continues to actively engage with all Aboriginal communities that have been identified as having an interest in the Project or have Aboriginal interests potentially affected by the Project. Engagement with Aboriginal communities is at varying stages in the engagement process. Specific detail about the engagement activities and the status of engagement with each group can be found in Section 1.5 of Volume 3B and within Appendix A of Volume 3B.

3.2.1.6 Incorporating Aboriginal Traditional Ecological Knowledge

TEK does not have a stand-alone section in the ESA. However, TEK information has been incorporated throughout Volumes 5A and 5B, where appropriate. TEK has contributed by supplementing the methodology of the fish and fish habitat, vegetation, wetlands, wildlife and wildlife habitat field studies. TEK has also contributed by adding results that western science may not have gathered or considered, confirmed results that had been collected through scientific field studies as well as identifying and confirming issues of concern that would need to be addressed in the ESA.

Review of collected TEK and discussions of potential Project-related effects and mitigation strategies described in this ESA were conducted directly with participating community members during the field surveys. Approximately 28 Aboriginal communities were engaged in the TEK program with over 200 participants involved in field surveys. Confirmation of the accuracy of the information incorporated and approval of the inclusion of the confidential and proprietary information in Project planning occurred in the field and during community follow-up results review (Table 3.2-1). The TEK collected has been incorporated into the fish and fish habitat, vegetation, wetlands, wildlife and wildlife habitat settings of this ESA (Section 5.0) and was used to assist in the assessment of the potential effects of the Project. The issues that were raised and where they are considered in Volume 5A ESA – Biophysical are summarized in Table 3.2-2.

3.2.2 Implementation

A number of methods have been used to inform Aboriginal communities, obtain feedback and identify issues about the Project including: Project letters; meetings; phone conversations; email dialogue; newsletters; public information sessions; the Project website; and over 4,000 engagement activities have been carried out to date. The results of these engagement efforts, in conjunction with the collection of TEK as described in Section 3.2.2.3, Environment Field Participation have contributed to the development of the ESA for the pipelines and facilities components of the Project (Volumes 5A and 5B), including mitigation and enhancement measures. A detailed overview of the engagement activities implemented to date and a detailed summary of engagement with each Aboriginal community is available in Volume 3B.

3.2.2.1 Employment, Education and Training

Trans Mountain is committed to supporting the sustainability of Aboriginal communities through the creation of employment opportunities over the life of the proposed Project and is committed to the development of an Aboriginal workforce through effective and accessible training programs to maximize participation in available employment opportunities.

As detailed in Volume 3B, Trans Mountain is working in partnership with communities to achieve the objectives of the Aboriginal Peoples Training Policy to enhance employment opportunities with all interested communities, including marine communities.

3.2.2.2 Project Letters, Update Newsletters and Trans Mountain Website

The communications materials forwarded to communities that might have an interest in the Project or have Aboriginal interests potentially affected by the Project by Trans Mountain included the following:

- Project notification and introduction letter;
- advanced notice of field study work letter and field study process brochure;
- Project update letters and newsletters including updates to the Project website content, regulatory filings and participation funding;
- letter invitations to meet to discuss routing options for those communities where the existing TMPL system encounters Indian Reserve (IR) lands; and

- Project Description as filed with the NEB.

The formal kick-off for Project engagement began with a Project notification letter sent from Ian Anderson, President, KMC on May 29, 2012. Three versions of the letter were created and distributed depending on community location and proximity to the pipeline right-of-way.

The ESA Approach Summary document issued in March 2013 intended to provide an overview of Trans Mountain's understanding of the environmental and socio-economic context of the Project at the time of its release. Since its release, Trans Mountain continues to actively engage with regulatory authorities, stakeholders and Aboriginal communities on the methods, indicators and spatial boundaries listed in the approach document. Methods, indicators, and spatial boundaries for many of the environmental and socio-economic elements were revised based on comments received. In May 2013, Trans Mountain filed the Project Description for the Trans Mountain Expansion Project with the NEB which included updated information on key issues and indicators.

Communication materials have been compiled to meet NEB filing requirements and details (including samples) of these materials are provided in Volume 3B.

3.2.2.3 Project Meetings

Following distribution of the Project notification letter, Trans Mountain contacted Aboriginal communities to set up in-person meetings to discuss the Project with Chief and Council, staff and community members. The primary purpose of Project meetings is to share Project-related information. For initial meetings specifically with Chief and Council or community staff, the primary objective is to determine the community's interest in engagement and to develop a process for involvement in Project activities. A presentation titled "Aboriginal Engagement Program: Trans Mountain Expansion Project" is used during initial meetings to share Project details with attendees (see Volume 3B). Copies of the presentation were left with attendees post-meeting. Routing maps and operational information is also discussed at Project meetings and questions from meeting attendees are addressed.

Meetings and community gatherings were arranged with the assistance of community council leadership and staff. In general, open houses and introductory meetings were conducted by both Trans Mountain and TERA, while TERA conducted subsequent meetings as representatives of Trans Mountain.

Meetings with Aboriginal leadership and staff, harvesters and trappers were an important method of engagement. Meetings were held to:

- introduce the Project (timelines, Project description, regulatory requirements and process);
- provide a broad understanding of the NEB process;
- discuss methods for conducting engagement in the community;
- negotiate work plans and funding for those Aboriginal communities who propose to conduct their own TLU studies or socio-economic data collection (further discussion in Volume 5B);
- initiate environmental field work;
- identify economic development opportunities;
- identify capacity issues with Aboriginal communities to address ability of the community to participate in the Project review;
- identify community concerns, interests and opportunities;
- obtain input and feedback on environmental field studies; and
- identify site-specific concerns and interests for harvesters.

Meetings with specific communities are summarized in Volume 3B. Table 3.2-2 provides further information regarding issues and concerns identified through Project-related meetings with Aboriginal communities.

3.2.2.4 Environmental Field Program Participation

The purpose of Aboriginal participation during the environmental field program is to incorporate Aboriginal views and the additional knowledge of the land that has accumulated over generations and passed down from the Elders into the consideration of potential Project-related environmental effects. The collection of TEK for the Project focused on Aboriginal additional knowledge of the land and field reconnaissance was conducted along Crown lands potentially disturbed by Project construction, including associated physical works and activities. The objectives of Aboriginal participation during the environmental field surveys are to:

- document the TEK of Aboriginal communities;
- augment the design and execution of the field surveys;
- inform baseline/existing conditions;
- identify potential effects of the Project on environmental resources;
- integrate TEK into the consideration and mitigation of environmental effects; and
- contribute to final Project design.

TERA, on behalf of Trans Mountain, was commissioned to facilitate the participation of potentially affected Aboriginal communities during the environmental field studies conducted for the Project. Engagement for the Project was initiated in spring 2012 and continued throughout 2013. Opportunities for Project participation were made available to potentially affected Aboriginal communities that have an interest in the Project, based on their proximity to the Project or their assertion of traditional and cultural rights of the land.

An important issue identified by the participating Aboriginal communities was the need for their participation and contribution to the environmental field programs, while balancing capacity limitations in their respective lands departments. The field program was designed to provide Aboriginal community members with the opportunity to provide TEK information to the ESA. Interpreters were made available in the field upon the request of a given community, as warranted. Dates detailed in Table 3.2-1 may not correspond to dates noted in the biophysical technical reports (Volume 5C). The reason for this discrepancy is that additional time was spent in the field with Aboriginal participants for mobilization and demobilization to study areas, pre-field work meetings, wrap up meetings and to evaluate alternate routes.

The methods used to determine how participants were to be involved in Project field surveys were common to all Aboriginal communities. Each field survey was discussed with the community, usually with staff from the lands department. This discussion included the details regarding the type of work to be conducted, the timing and the proposed locations. Based on the described field work to be conducted, the Aboriginal communities chose their own members who would participate in each program. The participating Aboriginal communities are listed in Table 3.2-1 from east to west in relation to the Project.

TABLE 3.2-1

ENVIRONMENTAL FIELD STUDY PARTICIPATION FOR THE PROJECT

Aboriginal Community	Winter Aquatics	Open Water Aquatics	Wildlife	Wetlands	Bryolichen Survey	Terrestrial Ecosystem Mapping	Rare Plant Survey	Follow-up Results Review
Edmonton to Hinton Segment								
Saddle Lake Cree Nation	--	May 7 to 15, 2013 May 22 to June 1, 2013 June 8 to 12, 2013	June 18 to 27, 2013 July 4 to 9, 2013	August 15 to 21, 2012 May 27 to June 1, 2013	May 20 to 21, 2013	May 18 to 27, 2013	June 7 to 13, 2013 June 18 to 29, 2013 July 16 to 22, 2013	November 28, 2013

A Band Counsel Resolution was received by Trans Mountain which delegated authority to the Nicola Tribal Association to act on behalf of Nooaitch Indian Band, Nicomen Indian and Shackan Indian Band for Project engagement. TEK from the Simpcw First Nation field participants was unavailable for inclusion in the application by TERA, however, all field participants contributed to the discussion of potential Project-related effects on resources and participated in the discussion of potential mitigation measures to reduce potential Project-related effects.

During the field surveys, traditional methods of resource procurement were discussed, as well as modern methods currently employed. Seasonality of resource harvesting was also important information shared by the Aboriginal participants. Geographical locations were identified, as were areas that are not used and the reasons why. Potential mitigation measures to reduce any Project-related effects on a resource were also discussed during the field surveys. Open discussions occurred regularly between participants and biophysical specialists regarding the resources present and available to Aboriginal communities. These discussions were important to help build relationships among the field crews. Aboriginal participants spoke about aspects of the environment that were important to them and the importance of the resource from a western science perspective was also discussed. The TEK collected during the field surveys has added results that western science may not have gathered or considered, confirmed results that had been collected through the field surveys, as well as identified and confirmed issues of concern to be addressed in the ESA. The TEK collected is also used to assist in the review of potential Project-related effects on environmental resources.

3.2.3 Summary of Outcomes of the Aboriginal Engagement Program for Biophysical Elements

The results of engagement have helped refine the ESA for the Project. With this information, Trans Mountain identified issues, addressed concerns and responded to questions. Engagement has also provided Aboriginal communities with an understanding of the Project.

Although a wide range of issues were raised by community members and representatives throughout the Aboriginal engagement process, recurring themes have emerged, including the following:

- protection of the environment and the potential effects of spills on land and in water including the marine environment;
- potential construction and operation effects on inland fisheries, wildlife health and habitat, aquifers, watercourse crossings and wetlands;
- effects of dredging in proximity to the Westridge Marine Terminal; and
- pollution at Westridge Marine Terminal.

Results of the engagement have been considered and incorporated throughout the ESA – Biophysical where relevant, including the effects assessment and mitigation and enhancement measures. The issues identified by participating Aboriginal communities through engagement activities for the Project are described in Table 3.2-2. References to where these issues are considered in the application are also provided Table 3.2-2. Detailed information on engagement activities conducted and opportunities provided for Project input to date with each Aboriginal community is presented in Appendix A of Volume 3B.

3.2.4 Future Aboriginal Engagement Activities

Following submission of the application to the NEB, including the ESA, Trans Mountain will continue engagement with Aboriginal communities to provide updates on the status of the Project and discuss proposed mitigation and enhancement measures. Information updates will continue to be sent to Aboriginal communities. From information sharing to continued environmental field studies to address interests and concerns, Trans Mountain is committed to the continuation of an effective engagement program that satisfies all parties. As described in Volume 3B, Trans Mountain will continue engagement through the regulatory process and into Project development and operations. Trans Mountain will also continue its liaison with the Crown and provide updates regarding Trans Mountain's engagement activities with Aboriginal communities potentially affected by the Project.

TABLE 3.2-2

SUMMARY OF INTERESTS OR CONCERNS IDENTIFIED THROUGH ENGAGEMENT ACTIVITIES WITH ABORIGINAL COMMUNITIES FOR THE PROJECT

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Potential loss of beaver habitat, beaver lodges and request to trap and release live beaver	Saddle Lake Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Aseniwuche Winewak Nation Lheidli T'enneh Simpcw First Nation Tk'emlúp Te Secwépemc	As part of Trans Mountain's commitment to environmental protection, Trans Mountain will minimize potential adverse effects to wetlands by expediting construction in and around wetlands, by restoring wetlands to their original configurations and contours, by segregating topsoil during excavation, by permanently stabilizing upland areas near wetlands as soon as possible after backfilling, by inspecting the right-of-way periodically during and after construction, and by repairing any erosion control or restoration features until permanent revegetation is successful. Trans Mountain will ensure that in Alberta, in the event that beaver dams or lodges will be disturbed, notification will be provided provincial permits will be obtained prior to commencing activities. In additional, DFO will be notified 14 days prior to beaver dam removal and removals will be conducted in accordance with conditions of DFO's Alberta *Operational Statement for Beaver Dam Removal*. In BC, in the event that beaver dams or lodges will be disturbed, notification will be submitted to the appropriate regional Habitat Officer of the MFLNRO at least 45 days prior to beaver dam removal, as per Section 40 of the *Water Regulation*. Following this notification, a Ministry of Natural Resource Operations Wildlife Sundry Permit will be obtained to remove a beaver dam. Standards and best practices for beaver dam removal are identified in the BC *Standards and Best Practices for Instream Works*. Further discussion is provided under wetlands and wildlife in Sections 5.8, 5.10, 7.2.8 and 7.2.10. Mitigation measures for wildlife and wetlands are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.8, 5.10, 7.2.8 and 7.2.10 Volume 5C Wetland Evaluation Technical Report Wildlife Technical Report Volume 6B

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Increased access for hunters during construction Increased lines-of-sight affecting predator-prey dynamics due to clearing activities Potential effects to wildlife and wildlife habitat Potential for construction activities to limit use of game trails, restricting wildlife movement	Sunchild First Nation Saddle Lake Cree Nation Enoch Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Aseniwuche Winewak Nation Lheidli T'enneh Simpcw First Nation Lhtako Dene Nation Whispering Pines (Clinton Indian Band) Lower Nicola Indian Band Nicola Tribal Association Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation Cheam First Nation Ts'elxweyeqw Tribe Management Limited Seabird Island Band Popkum First Nation Scowlitz First Nation Leq'á:mel First Nation Kwantlen First Nation	The three main components of habitat fragmentation are habitat loss, reduced habitat patch size and increased isolation of patches. Effects of habitat fragmentation will be reduced by alignment of the proposed route parallel to and contiguous with existing linear features, and minimizing the Project footprint to the maximum extent feasible. A suite of mitigation measures will be implemented to reduce the potential effects of the Project on wildlife habitat, movement and mortality risk. Mitigation to reduce effects on habitat, limit barriers to movement, avoid attraction of wildlife to the work site, minimize sensory disturbance and protect site-specific habitat features of importance is discussed in the Section 7.2.10 and the Pipeline EPP (Volume 6B). Trans Mountain will facilitate wildlife movement during construction by ensuring the contractor conducts work expeditiously to maintain a tight construction spread to reduce the duration of the open trench and to reduce potential barriers and hazards to wildlife, and by placing gaps in the pipe. During construction, Trans Mountain will manage access (human and predator) at slope changes, crossings (*i.e.,* watercourse, road, pipeline right-of-way and railway) and bends. Measures will be implemented to reduce access (human and predator) along the pipeline right-of-way and will include using woody debris as rollback, and planting trees and/or shrubs at select locations along the pipeline right-of-way. Where rollback and coarse woody debris are needed for access management, erosion control and habitat enhancement, the contractor will ensure that a sufficient supply is set aside for this purpose during final clean-up. Habitat connectivity will be restored by redistributing large-diameter slash (rollback) over select locations on the pipeline right-of-way (*e.g.,* where high levels of coarse woody debris occur prior to construction), to provide cover and facilitate movement of wildlife. Further discussion is provided under wildlife in Section 7.2.10 and the Wildlife Technical Report of Volume 5C. Mitigation measures for wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Section 7.2.10 Volume 5B Section 7.2.4 Volume 5C Wildlife Technical Report Volume 6B
Sensory disturbance to wildlife during construction activities	Enoch Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Simpcw First Nation	Trans Mountain recognizes that many regional changes have occurred since the pipeline was installed over 60 years ago including urban encroachment near some of its existing pump stations and terminals and is aware that noise during operations is of concern to nearby residents. Ambient sound surveys representative of sound levels at noise receptors and existing facilities will be conducted and, all noise level results will be compared to Alberta Energy Regulator's *Directive 038 Noise Control* and the BC OGC's *Noise Control Best Practices Guideline*. Trans Mountain will ensure equipment is well-maintained during construction to minimize air emissions and unnecessary noise. Additionally, Trans Mountain will restrict the duration that vehicles and equipment are allowed to sit and idle to less than one hour unless air temperatures are less than 0°C. Standard mitigation plus noise-specific mitigation measures will be implemented. Mitigation to reduce light and visual effects may include landscaping to limit visual effects to wildlife and the public (*i.e.,* leave a vegetation buffer) and installing lighting control systems in the facility site that permit the reduction of the amount of lighting during periods of low activity. Further discussion is provided under noise and wildlife in Sections 7.2.6, 7.2.10, 7.4.6 and 7.5.6 in Volume 5A and discussion of aesthetics/visual effects is provided under HORU in Sections 5.4 and 7.2.4 in Volume 5B. Mitigation measures for noise, wildlife and visual effects are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 7.2.6, 7.2.10, 7.4.6 and 7.5.6 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Terrestrial Noise and Vibration Technical Report Volume 5D Socio-Economic Technical Report Volume 6B Volume 6C

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Sweep for bear dens prior to construction Disturbance of wildlife dens during construction	Saddle Lake Cree Nation Enoch Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Aseniwuche Winewak Nation Lheidli T'enneh Simpcw First Nation Chawathil First Nation Scowlitz First Nation Leq'á:mel First Nation	In the event an active grizzly bear den is found, AESRD will be contacted to discuss mitigation strategies. Recommended setbacks are 750 m for high disturbance activities (*i.e.,* conventional pipelines) and 500 m for medium disturbance activities (*i.e.,* conventional pipeline parallel to a linear corridor) from October 1 to April 30. Trans Mountain will ensure the contractor implements a setback of 750 m for high disturbance activities (*i.e.,* conventional pipelines) and 500 m for medium disturbance activities (*i.e.,* conventional pipeline parallel to a linear corridor) in the event an active grizzly bear den is discovered from October 1 to April 30. In Alberta, in the event an active mammal den is found, a 100 m setback is recommended. Mitigation may include monitoring the den and/or modifying the construction schedule to avoid activity until the den is inactive. Further discussion is provided under wildlife in Section 7.2.10. Mitigation measures for wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6B See above
Effects on endangered species Potential effects to caribou and caribou habitat	Canim Lake Band Lower Nicola Indian Band Aseniwuche Winewak Nation Lheidli T'enneh Simpcw First Nation	RAPs, least risk work windows and setback distance guidelines will be considered under Alberta and BC frameworks to provide effective management for selected wildlife species. The contractor will notify the CWS if clearing of complex habitat (*e.g.,* forests) is scheduled to occur during the migratory bird nesting period; (May 7 to August 20 ([wetlands April 20 to August 25)] in Alberta; and March 15 to August 15 in BC. Additionally, Trans Mountain will discuss the timing of their activity with AESRD and BC regulatory authorities and maintain contact during the construction period to advise them of the construction progress and anticipated completion date within sensitive/key ecological areas. Construction, routine maintenance and operational activities will be scheduled outside the spring period for caribou (generally mid-March to mid-July), unless otherwise approved by AESRD. Further discussion is provided under wildlife and species at risk in Sections 7.2.10 and 7.2.11. Mitigation measures for wildlife and species at risk are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.10, 5.11, 7.2.10 and 7.2.11 Volume 6B
Loss of bat habitat during construction	Semiahmoo First Nation	The TMEP has the potential to affect bats and their habitat. In Alberta, roosts and hibernation sites of northern long-eared bats have a year round 300 m setback from high disturbance activities; 100 m setback from medium disturbance activities and a 50 m setback from low disturbance activities. In BC, bat roosts will be protected from disturbance by humans and other sensory disturbances. A 125 m buffer will be implemented from bat hibernacula (from October 1 to April 30 or maternity roost (from May 1 to August 31). If disturbance of a hibernacula or maternity roost is unavoidable, consultation with BC MFLNRO will be conducted to discuss practical options and mitigation strategies. Additionally, Trans Mountain will discuss the timing of their activity with AESRD and BC regulatory authorities and maintain contact during the construction period to advise them of the construction progress and anticipated completion date within sensitive/key ecological areas. Further discussion is provided under wildlife in Section 7.2.10. Mitigation measures for wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6B

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Potential effects to fish and habitat	Saddle Lake Cree Nation Enoch Cree Nation Alexander First Nation Samson Cree Nation Métis Nation of Alberta (Region 4) Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Aseniwuche Winewak Nation Lheidli T'enneh Simpcw First Nation Lhtako Dene Nation Canim Lake Band Whispering Pines (Clinton Indian Band) BC Metis Federation Tk'emlúp Te Secwépemc Lower Nicola Indian Band Nicola Tribal Association Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation Cheam First Nation Peters Band Seabird Island Band Popkum First Nation Scowlitz First Nation Leq'á:mel First Nation Semiahmoo First Nation Kwantlen First Nation Squamish First Nation Musqueam Indian Band Pacheedaht First Nation Ts'elxweyeqw Tribe Management Limited T'sou-ke First Nation	Trans Mountain agrees that measures to protect sensitive environmental areas such as water bodies and riparian areas are critical. Trans Mountain takes a multi-layered approach to pipeline safety, including adopting measures such as strategically placed pipeline valves near waterways and trenchless river crossings at some locations. Crossing methods specific to each watercourse will be determined in consultation with engineering and environmental specialists, as well as applicable regulatory authorities. Crossings of wetlands and watercourses will be planned during suitable ground and weather conditions with consideration for sensitive fish and wildlife timing windows. Additionally, water quality will be monitored during all instream activity. Each watercourse will be approached correctly so the cumulative effects of changes to all the crossings and the surrounding watershed will be limited. A summary of the watercourse crossings for the Project are provided in the Fisheries (Alberta) Technical Report and the Fisheries (BC) Technical Report in Volume 5C. Further discussion and mitigation measures to be implemented at watercourse crossings are mentioned under fish and fish habitat in Sections 5.7 and 7.2.7 and the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.7 and 7.2.7 Volume 5C Fisheries (Alberta) Technical Report Fisheries (British Columbia) Technical Report Volume 6B

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Sensory disturbance to birds and disturbance of bird habitat during construction	Saddle Lake Cree Nation Enoch Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Aseniwuche Winewak Nation Lheidli T'enneh Simpcw First Nation Canim Lake Band Whispering Pines (Clinton Indian Band) Lower Nicola Indian Band Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation Cheam First Nation Ts'elxweyeqw Tribe Management Limited Seabird Island Band Popkum First Nation Scowlitz First Nation Leq'á:mel First Nation	Trans Mountain will work with Environment Canada and comply with the *Migratory Birds Convention Act, 1999, Migratory Bird Sanctuary Regulations* and any provincial and territorial wildlife agencies related to the proposed Project components and effects. Clearing and preconstruction activities will be conducted outside the minimum migratory bird RAP of May 1 to July 31 where practical. Clearing and mowing outside of the appropriate timing window or within the migratory bird season RAP will only be allowed where nest surveys have been completed by a qualified Wildlife Resource Specialist within 7 days of the commencement of clearing and no nesting activity was observed within the applicable setback distance. In the event an active nest is found, a protective buffer will be established around the nest. The size of the buffer will be influenced by the status of the bird. The spatial boundaries of the survey will include at least 30 m beyond the staked construction boundaries for migratory song birds and 50 m in native grassland areas; and 100 m for raptors and waterfowl. If the active nest belongs to a bird with a species-specific buffer, then that buffer applies. In the event that a nest is discovered, an appropriate mitigation strategy will be selected by the Lead Environmental Inspector and Environmental Inspector(s) or Wildlife Resource Specialist from the Wildlife Species of Concern Discovery Contingency Plan (Appendix B of Volume 6B). Further discussion is provided under wildlife in Sections 5.10 and 7.2.10. Mitigation measures for wildlife, including bird habitat, are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report Volume 6B
Disturbance and loss of amphibian habitat during construction	Saddle Lake Cree Nation Alexander First Nation Samson Cree Nation Alexis Nakota Sioux First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Lower Nicola Indian Band Yale First Nation Leq'á:mel First Nation	Field surveys were conducted for wetlands along the proposed pipeline corridor to identify amphibian habitat. In Alberta, in the event that a western toad breeding pond is found, a year-round 100 m setback distance is recommended. In BC, identified amphibian breeding ponds will be protected by implementing appropriate buffers (150 m undeveloped; 100 m rural; 30 m urban). A year-round 400 m federal setback distance is recommended for western toad breeding ponds and wintering sites. If the proposed construction right-of-way is located within the recommended buffer, consultation will be conducted with the appropriate regulatory agencies to determine the appropriate mitigation measures. Standard wetland construction and reclamation mitigation will be applied (*e.g.,* minimal disturbance, recontouring, reclamation, monitoring and remedial measures) to support habitat reclamation as needed. The Contractor will ensure fencing is installed around wetlands for clearing and construction activities scheduled during the amphibian breeding period (spring), where warranted, to protect important habitat. Amphibian salvage will be conducted prior to clearing and construction activities at known amphibian breeding pond locations. Best Management Practices for Amphibian and Reptile Salvages in BC will be adhered to. Consultation with regulatory authorities will be conducted as appropriate if the proposed pipeline corridor is located within the recommended setback distance of an amphibian breeding pond. Further discussion is provided under wildlife in Section 7.2.10. Mitigation measures for wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.10 and 7.2.10 Volume 5C Wildlife Technical Report Volume 6B

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Potential loss of wetland habitat, function and water quality also affecting wildlife and vegetation during construction of the Project	Saddle Lake Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Lheidli T'enneh Canim Lake Band Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation Popkum First Nation Leq'á:mel First Nation	As part of Trans Mountain's commitment to environmental protection, Trans Mountain will minimize potential adverse effects to wetlands by expediting construction in and around wetlands, by restoring wetlands to their original configurations and contours, by segregating topsoil during excavation, by permanently stabilizing upland areas near wetlands as soon as possible after backfilling, by inspecting the right-of-way periodically during and after construction, and by repairing any erosion control or restoration features until permanent revegetation is successful. Crossings of wetlands and watercourses will be planned during suitable ground and weather conditions with consideration for sensitive fish and wildlife timing windows. Additionally, water quality will be monitored during all instream activity. Each watercourse will be approached correctly so the cumulative effects of changes to all the crossings and the surrounding watershed will be limited. A summary of the watercourse crossings for the Project are provided in the Fisheries (Alberta) Technical Report and the Fisheries (BC) Technical Report in Volume 5C. Further discussion is provided under fish and fish habitat and wetlands in Sections 5.7, 5.8, 7.2.7 and 7.2.8. Mitigation measures for fish and fish habitat and wetlands are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.7, 5.8 ,7.2.7, 7.2.8 and 8.6 Volume 5C Fisheries (Alberta) Technical Report Fisheries (British Columbia) Technical Report Wetland Evaluation Technical Report Volume 6B
Avoid loss of tree stands	Saddle Lake Cree Nation Enoch Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Lhtako Dene Nation Canim Lake Band Lower Nicola Indian Band Yale First Nation Shxw'ow'hamel First Nation Chawathil First Nation Cheam First Nation Seabird Island Band	One of Trans Mountain's objectives is to use, or abut, the existing TMPL right-of-way where practical. In some cases, trees can be a source of natural sound that masks man-made noises and provide a visual buffer to the right-of-way. Trans Mountain is committed to best practices in reclamation, always striving for opportunities leading to advancement. As with all of its construction projects, Trans Mountain will reclaim any areas that are affected by the Project. Trans Mountain is committed to reclamation of the pipeline right-of-way and surrounding areas following construction. Following construction, Trans Mountain aims to return the right-of-way to pre-construction conditions, to the extent practical. This could include adding new footpaths, developing new habitats, improving water crossings or bettering migration corridors. Reclamation efforts could include the planting of native plant and grass species, riparian and wetland areas, wildlife habitats and any other areas disturbed during construction. Post-construction environmental monitoring and ongoing right-of-way maintenance will continue following construction (see Volume 6A). If warranted, site-specific mitigation measures based on location and species will be determined once the route is finalized in accordance with the Rare Ecological Community and Rare Plant Population Management Plan (Appendix C of Volume 6B). Further discussion is provided under vegetation in Section 7.2.9. Mitigation measures for vegetation are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report Volume 6A Volume 6B Volume 6C

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Reclaim Project lands to pre-construction state	Saddle Lake Cree Nation Enoch Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Alexis Nakota Sioux First Nation Foothills Ojibway Society Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Canim Lake Band Tk'emlúp Te Secwépemc Chawathil First Nation Shxw'ow'hamel First Nation Ts'elxweyeqw Tribe Management Limited Musqueam Indian Band	Trans Mountain will implement the Reclamation Management Plan (Appendix C of Volume 6B) that includes construction reclamation measures to be implemented prior to, during and following pipeline installation in order stabilize and revegetate affected lands that in time achieve land productivity along the right-of-way equivalent to the adjacent land use and ensuring the ability of the land to support various land uses. Construction reclamation activities are measures conducted as part of the main construction program. The primary goal of reclamation measures is to reduce adverse effects of pipeline construction and return the affected lands to a stable, non-erosive condition that will promote the re-establishment of land productivity. This process involves measures such as: topsoil and root zone material salvage; subsoil conditioning and grade and drainage re-establishment; topsoil and root zone material replacement; installation and maintenance of temporary and permanent erosion and sediment control measures; and revegetation. During the 2012 and 2013 field seasons, a number of environmental and engineering field programs were conducted to assess existing conditions and types of land use in the Project area, as well as identify possible socio-economic effects. These programs occurred in both Alberta and BC, and involved the work of a number of teams in various disciplines. Trees, stumps, brush and other vegetation will be cleared from the construction right-of-way; temporary work sites; and permanent facilities that are not located on existing TMPL previously cleared easements. Timber harvesting and/or land clearing and debris disposal activities will be coordinated according to Provincial legislation or agreements. Where present in non-forested areas, topsoil/root zone material will be salvaged to ensure that soil productivity is maintained. The width and depth of topsoil or strippings salvage will depend on the land use, soil conditions, microtopography, regulatory authority requests and grading requirements. Any salvaged topsoil or root zone material will be separated from spoil piles and stored along the construction right-of-way and at facility sites in low-profile berms or windrows. Equipment used during topsoil/root zone material handling activities will include bulldozers, graders and backhoes. Lands in Alberta, and lands outside the Agricultural Land Reserve in BC, will be reclaimed with native and non-native seed mixes developed for the Project that are based on vegetation field survey data and will follow consultation with landowners/lessees or appropriate regulatory authorities. Discussions with the Agricultural Land Commission will be ongoing to discuss potential effects of the Project on Agricultural Land Reserve lands. Restoration and monitoring activities typically extend for a number of years following construction to ensure areas disturbed during construction are satisfactorily restored. Further discussion is provided under vegetation in Sections 5.9 and 7.2.9. Mitigation measures for vegetation are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report Volume 6A Volume 6B Volume 6C
Request for wildlife monitors during construction and post-construction site visits with Aboriginal communities Involve Elders in Project reclamation work	Enoch Cree Nation Samson Cree Nation Métis Nation of Alberta (Region 4) Tk'emlúp Te Secwépemc	Trans Mountain will continue to engage Aboriginal communities through all phases of the Project. The EPPs provide mitigation measures developed in response to issues identified during Project planning, stakeholder consultation, Aboriginal engagement and regulatory discussions. Aboriginal Monitors onsite through the construction to commissioning of the of the Project will work with environmental inspector to provide traditional knowledge to the construction program to ensure protection of the environment; to discuss upcoming traditional and western science elements with the environmental inspector to insure protection and monitoring; and to monitor mitigation success in protecting the environment. Aboriginal engagement is discussed in Volume 3B and the use of Aboriginal Monitors is discussed in Volume 6A. The Pipeline and Facilities EPPs can be found in Volumes 6B and 6C, respectively.	Volume 3B Volume 6A Volume 6B Volume 6C

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Spread of invasive species and use of chemical vegetation management	Saddle Lake Cree Nation Enoch Cree Nation Samson Cree Nation Alexander First Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Sunchild First Nation Nakcowinewak Nation Of Canada Aseniwuche Winewak Nation Lheidli T'enneh Canim Lake Band Lhtako Dene Nation Whispering Pines (Clinton Indian Band) Lower Nicola Indian Band Nicola Tribal Association Nooaitch Indian Band Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation Ts'elxweyeqw Tribe Management Limited Seabird Island Band Popkum First Nation Scowlitz First Nation Leq'á:mel First Nation Tzeachten First Nation Semiahmoo First Nation Kwantlen First Nation Squamish First Nation Musqueam Indian Band	Trans Mountain will utilize an Integrated Vegetation Management (IVM) approach to carry out problem vegetation management practices for the Project and to meet the overall objectives of IVM for all Trans Mountain pipelines and facilities. Trans Mountain will ensure the contractor implements weed management (*i.e.,* using proper application of chemical, mechanical or manual measures, or a combination of all) at locations identified within the pre-construction weed survey to a level that is consistent with weed management observed adjacent to the eventual construction right-of-way to reduce the potential for weed infestations following construction. The contractor will restrict all vehicular traffic to the approved and staked construction right-of-way, workspace and access roads. The contractor will also ensure equipment arrives at all construction sites clean and free of soil or vegetative debris. Inspect and identify equipment deemed to be acceptable with a suitable marker, such as a sticker. No equipment arriving in a dirty condition will be allowed on site until it has been cleaned. Trans Mountain will consult with the public, adjacent landowners and Aboriginal communities affected by the Project regarding problem vegetation management and methods of treatment. IVM is an adaptive management process involving the use of various methods in a cost effective and responsible manner to reduce the use of herbicides, promote healthy ecosystems, provide measurable results and facilitate better management of problem vegetation. The Weed and Vegetation Management Plan (Appendix C of Volume 6B) for the Project will address non-chemical, cultural and chemical techniques for problem vegetation management along the construction right-of-way through recommendations of vegetation management procedures, which include timing considerations; select methods and equipment; and specific vegetation management procedures based on prevention, identification, monitoring, treatment thresholds, vegetation management options and post-treatment evaluation considerations. Further discussion is provided under vegetation in Sections 5.9 and 7.2.9. Mitigation measures for vegetation are outlined in the Pipeline and Facilities EPPs (Volumes 6B and 6C).	Volume 5A Sections 5.9 and 7.2.9 Volume 5C Vegetation Technical Report Volume 6B Volume 6C
Soil Reclamation/Topsoil Salvage	Alexander First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Sunchild First Nation Paul First Nation Nakcowinewak Nation Of Canada Leq'á:mel First Nation	Where present in non-forested areas, topsoil/root zone material will be salvaged to ensure that soil productivity is maintained. The width and depth of topsoil/root zone material salvage will depend on the land use, soil conditions, microtopography, regulatory agency requests and grading requirements. Any salvaged topsoil/root zone material will be segregated and stockpiled along the construction right-of-way and at facility sites in low-profile berms or in piles adjacent to the site perimeter. An Agricultural Management Plan (Appendix C of Volume 6B) been developed to particularly reduce effects on agriculture, which includes measures related to proper soil handling and reseeding. Subsoil and topsoil stoniness on right-of-way will match that off right-of-way (stone size and density) on agricultural land and native grasslands. Further discussion is provided under soil and soil productivity in Sections 5.2 and 7.2.2. Mitigation measures for soil and soil productivity are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.2 and 7.2.2 Volume 5C Soils Technical Report Volume 6B

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Cumulative effects of industrial development on plants	Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Sunchild First Nation Lheidli T'enneh Lhtako Dene Nation Nicola Tribal Association Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation	Potential Project-related cumulative effects will be mitigated with implementation of the following design and construction measures. Align the proposed pipeline corridor to follow existing linear features such as pipelines and disturbed areas such as facilities/clearings to the extent practical. Encourage rapid regeneration of natural vegetation. The Project's contribution to cumulative effects with reasonably foreseeable developments is assessed in Section 8.0, including Project's contribution to cumulative effects on vegetation in Section 8.8. Mitigation measures are presented in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.9, 7.2.9, 8.0 and 8.8 Volume 6B
Post signage to share Aboriginal traditional plant use knowledge near the Project, excluding medicinal plant use or confidential knowledge	Enoch Cree Nation Alexander First Nation Métis Nation of Alberta (Region 4) Ermineskin Cree Nation Montana First Nation Paul First Nation Nakcowinewak Nation Of Canada Aseniwuche Winewak Nation Lheidli T'enneh Lhtako Dene Nation Whispering Pines (Clinton Indian Band) Tk'emlúp Te Secwépemc Lower Nicola Indian Band Nicola Tribal Association Yale First Nation Popkum First Nation Le'qa:mel First Nation	Trans Mountain is committed to continued listening, learning and working with Aboriginal people to ensure that knowledge and advice is fully considered and incorporated in the Project. Trans Mountain will continue to engage Aboriginal communities to identify continued opportunities for sharing of knowledge during all phases of the Project. Aboriginal engagement is discussed further in Volume 3B.	Volume 3B

TABLE 3.2-2 Cont'd

Summary of Interest or Concern	Aboriginal Community	Response Summary[1]	Where Issue is Addressed in the Application
Oil spills/leaks, concerns for speed of response if such a spill/leak was to occur	Saddle Lake Cree Nation Alexander First Nation Samson Cree Nation Ermineskin Cree Nation Montana First Nation Louis Bull Tribe Alexis Nakota Sioux First Nation Paul First Nation Nakcowinewak Nation Of Canada Sunchild First Nation Whispering Pines (Clinton Indian Band) Lower Nicola Indian Band Nicola Tribal Association Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation Cheam First Nation Ts'elxweyeqw Tribe Management Limited Popkum First Nation Scowlitz First Nation Leq'á:mel First Nation Tsleil-Waututh Nation Chemainus First Nation Cowichan Nation Aliance Halalt First Nation Penelakut First Nation	Safety is a top priority and is at the core of who Trans Mountain is as a company. Dedicated staff work to maintain the integrity of the pipeline through Trans Mountain's maintenance, inspection, and awareness programs. While no spill is acceptable to Trans Mountain, accidents can happen. Trans Mountain agrees that measures to protect sensitive environmental areas such as water bodies and riparian areas are critical. This is why Trans Mountain takes a multi-layered approach to pipeline safety, including taking measures such as strategically placed pipeline valves near waterways and drilled river crossings at some locations. Trans Mountain control centre operators monitor the pipeline 24 hours per day, 7 days a week, 365 days a year using a sophisticated leak detection system as well as pressure and flow alarms. Operators are prepared to shut the pipeline down immediately if there is any indication of a potential problem on the pipeline. In the event of an emergency, Trans Mountain will immediately mobilize all of the necessary resources to minimize its effect on the public and the environment. Trans Mountain has comprehensive spill response plans in place for the Trans Mountain pipeline and facilities. These plans are constantly being updated to keep them current and are regularly practiced through deployment exercises. While the specific strategies used in response to a spill will vary depending on the circumstances, the primary objectives in all cases are to ensure safety and to minimize environmental damage. To ensure there are sufficient funds to remediate a spill, Trans Mountain is covered by insurance necessary to respond to all spills or releases from Trans Mountain's pipelines and facilities. Trans Mountain monitors the insurance program continuously, and makes annual adjustments as necessary to ensure adequate coverage. Accidents and malfunctions are discussed in Section 7.9. Large onshore oil spills are discussed in Volume 7.	Volume 5A Section 7.9 Volume 6B Volume 6C Volume 7
Increased erosion and run-off	Alexander First Nation Ermineskin Cree Nation Alexis Nakota Sioux First Nation Paul First Nation Sunchild First Nation Lheidli T'enneh Whispering Pines (Clinton Indian Band) Yale First Nation Chawathil First Nation Shxw'ow'hamel First Nation Cheam First Nation Ts'elxweyeqw Tribe Management Limited Seabird Island Band Popkum First Nation Scowlitz First Nation Leq'á:mel First Nation Tsleil-Waututh Nation	If wind or water erosion is evident during the construction phase of the Project, contractor equipment and personnel will be made available to control the erosion. During the construction phase, the Environmental Inspector, in consultation with Trans Mountain's environmental staff, will determine appropriate procedures to be implemented to control soil erosion and other soil handling problems that may be encountered. Similar procedures will be followed during the operational phase. Further discussion is provided under soil and soil productivity in Sections 5.2, 7.2.2 and 7.4.2. Mitigation measures for soil and soil productivity are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.2, 7.2.2 and 7.4.2 Volume 5C Soils Technical Report Volume 6B

Note: 1 Detailed mitigation measures are outlined in the Project-specific EPPs (Volumes 6B, 6C and 6D).

3.3 Landowner Relations

The primary objectives of the landowner relations program were to introduce the Project to landowners and occupants and obtain approval for land access on a timely basis to support required engineering and environmental surveys. Over the long-term, the program objectives are obtaining landowner understanding, acceptance, and land rights for survey, construction, restoration and transition to operations. This approach also serves to preserve good relationships that currently exist and reinforce positive relations into operations.

Land stakeholder groups include private landowners, freehold and Crown occupants, and public landowners (federal, provincial, and municipal). Landowner issues include land rights, compensation, land-specific construction and restoration activities, as well as broader Project and policy issues. The program will attempt to engage all appropriate internal groups where necessary to address issues and concerns effectively.

Trans Mountain designed the program with the following objectives:

- introduce the Project to landowners in a manner that establishes a basis for a positive ongoing working relationship;
- support engineering and environment disciplines in determining Project routing and facility configuration by obtaining landowner survey consent;
- develop the Land Program Strategy to guide land rights acquisition;
- acquire necessary land rights to enable the Project to be constructed and placed into operation;
- obtain necessary third-party crossing approvals to enable the Project to be constructed safely;
- provide support to the regulatory applications and the regulatory process for the Project;
- support construction and restoration activities, including post-construction damage settlements; and
- transfer Project land information and landowner files to Trans Mountain Operations.

Trans Mountain recognizes the program must adapt to the needs of landowners and the Project, therefore, Trans Mountain will continuously review and assess the program to ensure that it is being conducted in the most effective and efficient manner.

3.3.1 Design of Program

Trans Mountain and its land agents began implementing the program in April 2012, and it continues to be an ongoing process. Internal processes within the program continue to evolve to better support the Project and in response to changes within engineering, environmental, and operational functions. A detailed description of the program is provided in Volume 3C.

3.3.1.1 Landowner Notification

Trans Mountain identified a proposed pipeline corridor of generally 150 m width along the entire length of the Project. The corridor typically follows the TMPL system right-of-way but deviations have been identified as necessary. A land titles search to confirm the land and interest ownership was then initiated for lands within the proposed pipeline corridor. As the Project route is finalized, additional landowners and occupants may be identified; contact with newly identified landowners and occupants will be consistent with the format identified in Section 1.3.3 of Volume 3A.

<u>Notification of Landowners</u>

Trans Mountain and its land agents commenced the program in April 2012 and it continues to be an ongoing process. To ensure that Trans Mountain introduced the Project to landowners along the existing system, an initial contact letter (Volume 3C) was sent to all 2,390 landowners.

An additional letter was hand delivered to all urban residents along the TMPL system right-of-way in Edmonton, Alberta, and the BC Lower Mainland in August 2012 to inform the residents that Trans Mountain intended to pursue alternative routing in their communities.

Notification of Crown Occupants

A mail out was conducted with select Crown tenure holders with interests crossed by the proposed pipeline corridor who had not been contacted via other methods (*e.g.,* through the lands team or other disciplines on the assessment team). The mail out process was designed to provide an opportunity for the selected tenure holders (*e.g.*, agricultural tenure holders, commercial recreation tenure holders, guide-outfitters and registered trap line tenure holders) to identify key concerns related to Project activities and/or provide feedback on land/resource use patterns that may be affected.

3.3.1.2 Consultation and Survey Consent

The program uses a direct contact approach as it enables Trans Mountain's land agents to personally provide information to landowners and occupants about the Project and proposed studies. It also provides landowners and Crown occupants an opportunity to ask questions and identify concerns about the Project or the TMPL. These questions and concerns are passed on to the Project team. Trans Mountain's intention is to provide response to each landowner or occupant's concern or issue. The process has begun and will continue through all phases of landowner and occupant engagement.

Landowners and occupants located within the proposed pipeline corridor and likely to be directly affected by the Project were requested to provide consent for engineering and environmental study. Requests were usually made face-to-face and written or verbal consent was accepted.

Along this corridor, 1,325 landowners and 295 Crown rights holders in Alberta were contacted. In BC, 4,013 landowners and 615 Crown rights holders and pending land purchasers were contacted (Table 3.3-1).

TABLE 3.3-1

LANDOWNERS AND OCCUPANTS WITHIN THE PROPOSED PIPELINE CORRIDOR

Group	Alberta	BC	Total
Private Landowners	1,325	4,013	5,338
Crown Occupants and Pending Purchasers	295	615	910
Total	1,620	4,628	6,248

The approach provided an opportunity to collect information on aspects of the land which could be helpful in defining a route or potential effects of the Project on the environment.

Communication with landowners and occupants is ongoing and questions or concerns will continue to be addressed throughout the life of the Project.

3.3.1.3 Corridor Survey Limitations

Landowners and Occupants

Some landowners and occupants refused to provide consent for surveys. Surveys were not completed on those respective land parcels. The occurrences of refusal are intermittently distributed throughout the length of the Project.

The reasons, when provided, varied substantially. Where opportunities existed, an agent revisited the landowner or occupant to verify their position or determine if circumstances had changed that would allow provision of consent.

Some landowners and occupants consented to survey but such surveys were to be restricted to the TMPL right-of-way only. Areas between the right-of-way and the proposed pipeline corridor boundaries were not accessible.

BC Provincial Parks

Application was made to BC Parks in December 2012 for an Education and Research Park Use Permit to conduct environmental studies within BC Parks. In June 2013, BC Parks requested the application be revised and re-submitted for only intrusive types of surveys (*e.g.*, ground disturbances and electro-fishing). With permission from BC Parks, certain non-intrusive studies have been conducted on some Park lands. The Education and Research Park Use permit application was approved on November 15, 2013.

Indian Reserves

The TMPL crosses 15 IRs and the Aboriginal engagement team is involved in various stages of negotiation with each of the respective Aboriginal communities. Some Aboriginal communities have provided explicit consent for surveys, while others are anticipated to provide a decision on the matter in the near future.

Tk'emlúps Te Secwépemc

Tk'emlúps Te Secwépemc requested Trans Mountain to defer environmental field studies on traditional lands until Tk'emlúps Te Secwépemc was prepared to participate. The request affected studies within the corridor from the proposed Black Pines Pump Station in BC (reference kilometre [RK] 811.9) to Trans Mountain's Stump Pump Station (RK 862.7). Trans Mountain respected their request and postponed studies in June 2013 and part of July 2013. Further delay would result in lost study opportunities due to seasonal effects; therefore, with permission from Tk'emlúps Te Secwépemc, Trans Mountain resumed environmental studies on the traditional lands.

3.3.1.4 Land Acquisition

Section 5.4 of Volume 2 provides a detailed description of Land Acquisition.

3.3.1.5 Ongoing Relations

Trans Mountain will remain in contact with affected landowners and occupants throughout the Project life. Questions or concerns regarding the Project will be addressed as they arise. Once system operations commence, all landowner information will be transferred to Trans Mountain operations as the permanent record of land data.

3.3.2 Summary of Outcomes of the Public Consultation Program as it Relates to Biophysical Elements

The data presented in this subsection was collected from April 2012, to July 31, 2013. Updates from the program will be filed with the NEB as updates when requested.

Landowner meetings comprised discussions about the Project in general as well as requests for consent for Project-specific surveys. The meetings also provided an opportunity for landowners to ask questions and identify concerns regarding the Project. Tables 3.3-2 to 3.3-9 provide information on the key topics relating to the biophysical assessment and where these topics are addressed in the application.

3.3.2.1 Physical and Meteorological Environment

TABLE 3.3-2

INTERESTS OR CONCERNS RELATED TO PHYSICAL AND METEOROLOGICAL ENVIRONMENT

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner noted area prone to rockslide; flood control done by province in 1971	The TMEP will be incorporated into Trans Mountain's existing Pipeline Integrity Program. Trans Mountain's Pipeline Integrity Program has years of experience maintaining the existing TMPL. Through the Pipeline Integrity Program, Trans Mountain performs aerial surveillance to monitor for geotechnical events – such as landslides, hydrological (stream or river crossings) or third-party activity at least once a month for every section of the route. Additionally, on-ground surveys of all water crossings take place on a regularly scheduled basis. A discussion of geotechnical issues is provided under physical and meteorological environment in Sections 5.1 and 7.2.1. Additional details and site-specific information on terrain and natural hazards is provided in the Terrain Mapping and Geohazard Inventory of Volume 4A.	Volume 5A Sections 5.1 and 7.2.1 Volume 4A Terrain Mapping and Geohazard Inventory

3.3.2.2 Soil and Soil Productivity

TABLE 3.3-3

INTERESTS OR CONCERNS RELATED TO SOIL AND SOIL PRODUCTIVITY

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Property is a potato farm. Occupant has soil handling concerns. The occupant also advised that the potato farm has had potato cyst nematode issues	An Agricultural Management Plan (Appendix C of Volume 6B) has been developed to particularly reduce effects on agriculture, which includes measures related to topsoil handling, soil compaction, management of crop disruption, and crop and productivity loss. A discussion of soils, including potato cyst nematode, is provided under soil and soil productivity in Sections 5.2, 7.2.2 and 7.2.4. Mitigation measures are outlined in the Pipeline and Facilities EPPs (Volume 6B and 6C).	Volume 5A Sections 5.2, 7.2.2 and 7.4.2 Volume 5C Soils Technical Report Volume 6B Volume 6C
Several landowner concerns over the spread of clubroot	Generally, the best available mitigation for the spread of clubroot is to clean equipment involved in topsoil handling so that topsoil is not carried from landowner to landowner and/or from county to county, as presented in the Alberta *Clubroot Management Plan* (Alberta Agriculture and Rural Development 2010) and CAPP *Best Management Practices for Clubroot Disease* (CAPP 2008). A discussion of clubroot is provided under soil and soil productivity in Sections 5.2 and 7.2.2. Mitigation measures for clubroot are outlined in the Pipeline EPP (Volumes 6B).	Volume 5A Sections 5.2 and 7.2.2 Volume 5C Soils Technical Report Volume 6B
Landowner voiced concerns over ditch compaction	A detailed soil survey of soils with agricultural capability was conducted for the TMEP and soils susceptible to compaction and rutting have been identified. An Agricultural Management Plan (Appendix C of Volume 6B) has been developed to particularly reduce effects on agriculture, which includes measures related to soil compaction. A discussion of soils is provided under soil and soil productivity in Sections 5.2 and 7.2.2. Mitigation measures to reduce soil compaction are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.2 and 7.2.2 Volume 5C Soils Technical Report Volume 6B

TABLE 3.3-3 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner concerns regarding excess rocks on right-of-way prior to seeding	A detailed soil survey of soils with agricultural capability was conducted for the TMEP and excessively stony soils have been identified. Trans Mountain will pick stones on cultivated, hayland, pasture and native grassland land uses so that the stone content of exposed subsoils that have been disturbed by construction activity is equivalent to that of exposed subsoils that have not been disturbed. After topsoil replacement, stones will be picked on agricultural and native grasslands so that the construction right-of-way surface is equivalent (*i.e.,* stone size and density) to that of adjacent lands. Stones will be disposed of at locations approved by landowner or appropriate regulatory authority, where warranted. A discussion of soils is provided under soil and soil productivity in Sections 5.2 and 7.2.2. Mitigation measures for excess subsoil and topsoil stoniness are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.2 and 7.2.2 Volume 5C Soils Technical Report Volume 6B
Landowner concern regarding proper soil handling and accuracy, excess stoniness and roots, and proper reseeding as per landowner preference	Where present in non-forested areas, topsoil or root zone material will be salvaged to ensure that soil productivity is maintained. A detailed soil survey of soils with agricultural capability was conducted for the TMEP that identified the soil series encountered along the proposed pipeline corridor. The width and depth of topsoil or root zone material salvage will depend on the land use, soil conditions, microtopography, regulatory authorities' requests and grading requirements. Any salvaged topsoil or root zone material will be segregated and stockpiled along the construction right-of-way and at facility sites in low-profile berms or in piles adjacent to the site perimeter. An Agricultural Management Plan (Appendix C of Volume 6B) has been developed to reduce effects on agricultural lands, which includes measures related to proper soil handling and reseeding. Subsoil and topsoil stoniness on right-of-way will be equivalent to that off right-of-way (stone size and density) on agricultural land and native grasslands. A discussion of soils is provided under soil and soil productivity in Sections 5.2 and 7.2.2. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.2 and 7.2.2 Volume 5C Soils Technical Report Volume 6B

3.3.2.3 *Water Quality and Quantity*

TABLE 3.3-4

INTERESTS OR CONCERNS RELATED TO WATER QUANTITY AND QUALITY

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner requests testing of wells, concerned about water backing up and flooding Landowner water quality concerns and testing requirements in the event water backs up into well Potential concern regarding drainage and lagoon Landowner concerned about flooding water well from construction Landowner concerned that the disturbance during construction could lead to silt in water well and lower water quality Several general landowner concern regarding effects to nearby wells	Trans Mountain has conducted groundwater studies to determine water wells in proximity to the proposed pipeline corridor. Prior to construction, Trans Mountain's Hydrogeological Professional, in consultation with landowners and the appropriate regulatory authorities, will determine if springs and wells used for domestic purposes located within the immediate vicinity of the construction right-of-way will be sampled for water quality and flow rate prior to the commencement of construction. Trans Mountain will re establish or replace a potable water supply, as required, should a registered or known water well located within 30 m of the construction right-of-way be damaged (*i.e.,* diminishment in quantity and/or quality) during pipeline installation. Trans Mountain will follow-up with landowner to gather details of flooding concern. A discussion of groundwater quality and quantity is provided under water quality and quantity in Sections 5.3 and 7.2.3. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.3 and 7.2.3 Volume 5C Groundwater Technical Report Volume 6B
Landowner concerns regarding the potential for erosion from drainage corridor across the pipeline, as well as bank destabilization and subsequent flooding	The Reclamation Management Plan (see Appendix C of Volume 6B) will be implemented to re-establish stream banks and approaches, and restore natural drainage patterns following construction, and appropriate erosion control measures will be implemented. Post-construction environmental monitoring and ongoing right-of-way maintenance will identify areas where additional erosion and drainage control as well as bank stabilization measures are required. A discussion of erosion and watercourse crossing mitigation and reclamation strategies is provided under water quality and quantity and fish and fish habitat in Sections 5.3, 5.7, 7.2.3 and 7.2.7. Mitigation measures are outlined in the Pipeline EPP (Volume 6B), while post-construction environmental monitoring is discussed in Volume 6A.	Volume 5A Sections 5.3, 5.7, 7.2.3 and 7.2.7 Volume 5C Fisheries (Alberta) Technical Report Fisheries (British Columbia) Technical Report Volume 6A Volume 6B
Several landowner concerns regarding stream crossings on property	Trans Mountain conducted studies along the proposed pipeline corridor to identify all watercourse crossings. Appropriate watercourse crossing methods have been selected in consideration of the size, environmental sensitivities of the watercourse and the period of construction. Each watercourse will be approached correctly so the cumulative effects of changes to all the crossings and the surrounding watershed would be limited. Further discussion is provided under water quality and quantity and fish and fish habitat in Sections 5.3, 5.7, 7.2.3 and 7.2.7. Mitigation measures are outlined in the Pipeline EPP (Volume 6B), while post-construction environmental monitoring is discussed in Volume 6A.	Volume 5A Sections 5.3, 5.7, 7.2.3 and 7.2.7 Volume 5C Fisheries (Alberta) Technical Report Fisheries (British Columbia) Technical Report Volume 6A Volume 6B
The landowner is concerned with the quality and production of the six artisan springs on the property being affected	Prior to construction, Trans Mountain's Hydrogeological Professional, in consultation with landowners and the appropriate regulatory authorities, will determine if springs and wells used for domestic purposes located within the immediate vicinity of the construction right-of-way will be sampled for water quality and flow rate prior to the commencement of construction. A discussion of groundwater quality and quantity is provided under water quality and quantity in Sections 5.3 and 7.2.3. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.3 and 7.2.3 Volume 5C Groundwater Technical Report Volume 6B

TABLE 3.3-4 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner is concerned regarding the aquifer as it is the only source of drinking water in Chilliwack, BC	Trans Mountain will assess water quality and/or quantity changes to nearby groundwater which may result in adverse effects for other stakeholder or environmental receptors. Trans Mountain reviewed existing geological, hydrogeological and other information to determine potential hydrogeological conditions along the pipeline right-of-way and proposed facilities; GIS mapping and assessment strategies were applied. Trans Mountain developed site-specific hydrogeological investigation activities that included field verified surveys, hydraulic response testing, monitoring requirements and water quality parameter surveys. A discussion of groundwater quality and quantity is provided under water quality and quantity in Sections 5.3 and 7.2.3. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.3 and 7.2.3 Volume 5C Groundwater Technical Report Volume 6B

3.3.2.4 Acoustic Environment

TABLE 3.3-5

INTERESTS OR CONCERNS RELATED TO ACOUSTIC ENVIRONMENT

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Increased noise near residence from pipeline construction Increased noise in town during construction where there are many residential properties	Pipeline construction is expected to last for approximately 3 months at any location along the propose pipeline corridor. However, within that period, the various phases of construction will occur consecutively. Noise, dust and other disturbances are mitigated to avoid the effects on people near the construction. Ambient sound surveys representative of sound levels at noise receptors and existing facilities were conducted and, all noise level results were compared to Alberta Energy Regulator's *Directive 038 Noise Control* and the BC OGC's *Noise Control Best Practices Guideline*. Standard mitigation such as maintaining equipment in good working condition and maintaining noise suppression equipment on all construction machinery and vehicles in good order will be implemented. In urban environments, Trans Mountain will prepare noise management plan for implementation during construction. A discussion of noise during pipeline construction and operations is provided under acoustic environment in Sections 5.6 and 7.2.6 of Volume 5A. In addition, noise as a sensory disturbance to residents and other land users, is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.6 and 7.2.6 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Terrestrial Noise and Vibration Technical Report Volume 5D Socio-Economic Technical Report Volume 6B

TABLE 3.3-5 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner property located near pump station; raised noise, light and visual concerns Several landowner concerns regarding excessive noise at existing pump stations. Requesting sound surveys to ensure noise is within regulation	Trans Mountain will ensure equipment is well-maintained during construction to minimize air emissions and unnecessary noise. Additionally, Trans Mountain will restrict the duration that vehicles and equipment are allowed to sit and idle to less than 1 hour unless air temperatures are less than 0°C. Trans Mountain recognizes that many regional changes have occurred since the pipeline was installed over 60 years ago including urban encroachment near some of its existing pump stations and terminals and is aware that noise during operations is of concern to nearby residents. Ambient sound surveys representative of sound levels at noise receptors and existing facilities were conducted and, all noise level results were compared to Alberta Energy Regulator's *Directive 038 Noise Control* and the BC OGC's *Noise Control Best Practices Guideline*. Standard mitigation plus noise-specific mitigation measures will be implemented. Mitigation to reduce light and visual effects may include landscaping to limit visual effects to wildlife and the public (*i.e.,* leave a vegetation buffer) and installing lighting control systems in the facility site that permit the reduction of the amount of lighting during periods of low activity. A discussion of noise during construction and operations is provided under acoustic environment in Sections 5.6, 6.0, 7.2.6, 7.4.6 and 7.5.6 of Volume 5A. In addition, noise and visual sensory disturbance to residents and other land users is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline and Facilities EPPs (Volume 6B and 6C).	Volume 5A Sections 5.6, 6.0, 7.2.6, 7.4.6 and 7.5.6 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Terrestrial Noise and Vibration Technical Report Volume 5D Socio-Economic Technical Report Volume 6B Volume 6C
Landowner concern regarding vibrations caused during pipeline construction and potential damage to residence	Pipeline construction is expected to last for approximately 3 months at any location along the propose pipeline corridor. However, within that period, the various phases of construction will occur consecutively. In areas where there may be a concern regarding the safety of the public, restricted areas are established. Noise, dust and other disturbances are mitigated to avoid effects on people near the construction. The issue of noise vibration is provided under acoustic environment in Sections 5.6 and 7.2.6 of Volume 5A. In addition, noise as a sensory disturbance to residents and other land users is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.6 and 7.2.6 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Terrestrial Noise and Vibration Technical Report Volume 5D Socio-Economic Technical Report Volume 6B

3.3.2.5 Wetlands

TABLE 3.3-6

INTERESTS OR CONCERNS RELATED TO WETLANDS

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner voiced concern over a nearby wetland and the potential effects on the beaver that lives in the wetland Landowner voiced concern over a nearby wet area	As part of Trans Mountain's commitment to environmental protection, Trans Mountain will minimize potential adverse effects to wetlands by expediting construction in and around wetlands, by restoring wetlands to their original configurations and contours, by segregating topsoil during excavation, by permanently stabilizing upland areas near wetlands as soon as possible after backfilling, by inspecting the right-of-way periodically during and after construction, and by repairing any erosion control or restoration features until permanent revegetation is successful. Further discussion is provided under wetlands in Sections 5.8 and 7.2.8, as well as wildlife in Sections 5.10 and 7.2.10. Mitigation measures for wetlands and wildlife are outlined in the Pipeline EPP (Volume 6B).	Volume 5A Sections 5.8, 5.10, 7.2.8 and 7.2.10 Volume 5C Wetland Evaluation Technical Report Wildlife Technical Report Volume 6B

3.3.2.6 Vegetation

TABLE 3.3-7

INTERESTS OR CONCERNS RELATED TO VEGETATION

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner voiced concerns over crop growth on right-of-way, tree removal, fencing and cattle trampling newly seeded area on the right-of-way	An Agricultural Management Plan (Appendix C of Volume 6B) has been developed to particularly reduce effects on agricultural lands, which includes measures related to weed management, re-seeding, soil compaction, livestock access, drainage and irrigation lines, management of crop disruption, and crop and productivity loss. Trans Mountain will install temporary fences, if warranted, to restrict grazing and trampling of the seeded construction right-of-way until vegetation becomes established or less palatable. Further discussion is provided under vegetation in Sections 5.9 and 7.2.9, while agricultural land use is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B. Mitigation measures for agriculture and vegetation are outlined in the Pipeline EPP (Volume 6B), while post-construction environmental monitoring is discussed in Volume 6A.	Volume 5A Sections 5.9 and 7.2.9 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Soils Technical Report Vegetation Technical Report Volume 5D Agricultural Assessment Technical Report Socio-Economic Technical Report Volume 6A Volume 6B
Numerous landowners voiced concerns about weeds and weed control methods	Trans Mountain takes responsibility for returning any lands disrupted during construction to the same, or better condition than existed before construction (within the confines of safe right-of-way management). Trans Mountain will work with the landowner to address his concerns about the use of herbicides and weed control, however, Trans Mountain does not take responsibility for private landscaping needs unrelated to construction. Weed control will comply with local standards, KMC's policy and the Project's EPP. A Weed and Vegetation Management Plan (Appendix C of Volume 6B) has been developed to prevent the introduction and spread of weeds during construction. Post-construction environmental monitoring and ongoing right-of-way maintenance will continue with efforts such as weed management, seeding and planning in selected areas. Mitigation measures are discussed under vegetation in Section 7.2.9 and in the Pipeline EPP (Volume 6B), while post-construction environmental monitoring is discussed in Volume 6A.	Volume 5A Sections 5.9 and 7.2.9 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Soils Technical Report Vegetation Technical Report Volume 5D Agricultural Assessment Technical Report Volume 6A Volume 6B

TABLE 3.3-7 Cont'd

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Landowner opposed to any increase in right-of-way width and has concerns with ability to restore right-of-way to original condition Numerous landowners voiced concerns regarding tree removal and vegetation management/reclamation	One of Trans Mountain's objectives is to use, or abut, the existing right-of-way where practical. The landowners concern with respect to potentially increased right-of-way width will be considered. In some cases, trees can be a source of natural sound that masks man-made noises and provide a visual buffer to the right-of-way. Trans Mountain will endeavour to mitigate effects to landowners. If tree removal is unavoidable, discussions with the landowner may lead to agreement of some form of reclamation or compensation. Trans Mountain is committed to industry accepted best practices in reclamation, always striving for opportunities leading to advancement. As with all of its construction projects, Trans Mountain will reclaim any areas that are affected by the Project. Trans Mountain is committed to reclamation of the pipeline right-of-way and surrounding areas following construction. Following construction, Trans Mountain aims to return the right-of-way to pre-construction conditions, to the extent possible. This could include replacing footpaths, restoring habitats, improving water crossings or bettering migration corridors. Reclamation efforts could include the establishment of native plant and grass species, riparian and wetland areas, wildlife habitats and any other areas disturbed during construction. Post-construction environmental monitoring and ongoing right-of-way maintenance will continue following construction. Further discussion is provided for vegetation and other biophysical elements in Sections 5.0 and 7.0. Mitigation and reclamation measures, including a Reclamation Management Plan, are outlined in the Pipeline EPP (Volume 6B), while post-construction environmental monitoring is discussed in Volume 6A.	Volume 5A Sections 5.0 and 7.0 Volume 6A Volume 6B
Landowners concerns regarding loss of vegetation along right-of-way and exposure to highway	The primary design objective is to construct the Project within the existing pipeline right-of-way, and where this is not possible, minimize any new linear disturbance. Trans Mountain takes responsibility for returning any lands disrupted during construction to the same, or better condition than existed before construction (within the confines of safe right-of-way management). Trans Mountain would work with each landowner on this and could involve such things as replanting appropriate vegetation, recontouring and monitoring for weed invasion. Mitigation measures are discussed under vegetation in Section 7.2.9 of Volume 5A and in the Pipeline EPP (Volume 6B). In addition, visual sensory disturbance to residents and other land users is discussed under human occupancy and resource use in Sections 5.4 and 7.2.4 of Volume 5B.	Volume 5A Sections 5.9 and 7.2.9 Volume 5B Sections 5.4 and 7.2.4 Volume 5C Vegetation Technical Report Volume 5D Socio-Economic Technical Report Volume 6B
Landowner concerns regarding sensitive grasslands	Trans Mountain takes responsibility for returning any lands disrupted during construction to the same, or better condition than existed before construction (within the confines of safe right-of-way management). A comprehensive environmental assessment was completed for the Project. Over 30 types of environmental surveys were completed by local and regional biologists, botanists and resource specialists. The results of the surveys are provided in Volume 5C. Species of special status and their habitats were identified and assessed as part of the Project. Pipeline construction is a sequential series of activities, which do not remain in one area for an extended period of time. Detailed EPPs have been submitted to the NEB as part of the application, which document the construction right-of-way and provide mitigation strategies to help avoid or minimize environmental effects from construction. The Reclamation Management Plan (Appendix C of Volume 6B) will be implemented and post-construction environmental monitoring and ongoing right-of-way maintenance will continue with efforts such as weed management, seeding and planning in selected areas. Mitigation measures are discussed under vegetation in Section 7.2.9 and in the Pipeline EPP (Volume 6B), while post-construction environmental monitoring is discussed in Volume 6A.	Volume 5A Section 7.2.9 Volume 5C Vegetation Technical Report Volume 6A Volume 6B

3.3.2.7 Wildlife and Wildlife Habitat

TABLE 3.3-8

INTERESTS OR CONCERNS RELATED TO WILDLIFE AND WILDLIFE HABITAT

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Potential fox den on property	Wildlife habitat features, such as an active fox den, will be reviewed prior to construction to determine their status and the appropriate mitigation (*e.g.*, setback and timing window) will be applied that is consistent with provincial regulatory guidance. Trans Mountain will work with regulatory authorities to discuss appropriate alternate mitigation in the event that the recommended setback/timing window from an active mammal den cannot be practically implemented during construction. Alternative mitigation may include monitoring the den and/or modifying the construction schedule to avoid activity until the den is no longer active.	Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6B
Landowners concerned about the potential effects to ravines on property used as wildlife bedding grounds	Project routing criteria include avoidance of environmentally sensitive areas, to the extent practical. Where sensitive areas cannot be practically avoided, alignment of the proposed route parallel to and contiguous with existing linear disturbances will minimize the Project footprint within sensitive areas, and mitigation will be implemented to reduce the Project's residual effects. A suite of mitigation measures will be implemented to reduce the potential effects of the Project on wildlife habitat, movement and mortality risk. Mitigation to reduce effects on habitat, limit barriers to movement, avoid attraction of wildlife to the work site, minimize sensory disturbance and protect site-specific habitat features of importance is discussed in the ESA sections noted.	Volume 4A Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6A Volume 6B
Landowners advised that the two concrete silos near or on the existing right-of-way contain barn owls and pigeons Landowner advised that in the creek on subject property, there are frogs that are a species at risk	A suite of mitigation measures have been proposed to reduce Project effects on wildlife and wildlife habitat. In addition, Trans Mountain has initiated discussions with Environment Canada and BC MFLNRO regarding development of additional mitigation strategies, where warranted, to address potential Project effects on species at risk and their habitat. Trans Mountain will continue to engage landowners regarding routing and mitigation to address the Project effects on species at risk and their habitat. Wildlife surveys were conducted for the Project in 2013. Supplemental surveys will be conducted, where warranted. The results of field studies will be used to inform mitigation strategies for the Project.	Volume 4A Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6A Volume 6B
Landowner concern regarding eagle nest on property	The mitigation measures proposed to reduce potential Project effects on nesting raptors have been developed to be consistent with provincial regulatory guidance. Measures are detailed in the ESA sections noted, and include establishment of setbacks or protective buffers, scheduling clearing in proximity to active nests outside of sensitive periods, and development of Nest Management Plans and installation of replacement structures, where warranted. Trans Mountain will work with regulatory authorities to cooperatively develop appropriate mitigation strategies, and will continue to engage landowners regarding routing and mitigation to address the Project effects on wildlife and wildlife habitat.	Volume 4A Volume 5A Section 7.2.10 Volume 5C Wildlife Technical Report Volume 6A Volume 6B

3.3.2.8 Ecological Risk

TABLE 3.3-9

INTERESTS OR CONCERNS RELATED TO ECOLOGICAL RISK

Summary of Interest or Concern	Response Summary	Where Issue is Addressed in the Application
Several landowner concerns regarding the potential environmental effects to land and/or water, including groundwater and salmon-bearing watercourses, that may be caused by a break in the line or spill during construction or operation	Safety is a top priority and is at the core of who Trans Mountain is as a company. Dedicated staff work to maintain the integrity of the pipeline through Trans Mountain's maintenance, inspection, and awareness programs. While no spill is acceptable to Trans Mountain, accidents can happen. Trans Mountain agrees that measures to protect sensitive environmental areas such as water bodies and riparian areas are critical. This is why Trans Mountain takes a multi-layered approach to pipeline safety, including taking measures such as strategically placed pipeline valves near waterways and drilled river crossings at some locations. Trans Mountain control centre operators monitor the pipeline 24 hours per day, 7 days a week, 365 days a year using a sophisticated leak detection system as well as pressure and flow alarms. Operators are prepared to shut the pipeline down immediately if there is any indication of a potential problem on the pipeline. In the event of an emergency, Trans Mountain will immediately mobilize all of the necessary resources to minimize its effects on the public and the environment. Trans Mountain has comprehensive spill response plans in place for the Trans Mountain pipeline and facilities. These plans are constantly being updated to keep them current and are regularly practiced through deployment exercises. While the specific strategies used in response to a spill will vary depending on the circumstances, the primary objectives in all cases are to ensure safety and to minimize environmental damage. To ensure there are sufficient funds to remediate a spill, Trans Mountain is covered by insurance necessary to respond to all spills or releases from Trans Mountain's pipelines and facilities. Trans Mountain monitors the insurance program continuously, and makes annual adjustments as necessary to ensure adequate coverage. Further discussion and mitigation for spills during construction or operation are provided in Sections 5.0 and 7.0 of Volume 5A and the Pipeline and Facilities EPPs (Volumes 6B and 6C). Pipeline spills during operation are discussed in Volume 7.	Volume 5A Sections 5.0 and 7.0 Volume 6B Volume 6C Volume 7

4.0 CORRIDOR AND FACILITY SITE SELECTION

The Project includes further looping of the existing 1,150 km TMPL system from Edmonton to Burnaby in operation since 1953. The 987 km of pipeline that will be looped as part of TMEP traverses a wide range of landforms from flat farmland to mountainous terrain. Land use varies from densely populated urban areas around Edmonton, Vancouver and elsewhere to sparsely populated rural agricultural and forested Crown lands. The pipeline segments to be constructed as part of the Project will also potentially cross over 500 rivers and streams, 8 provincial parks and 13 Indian Reserves (IRs).

An overview of the general routing objectives/criteria and proposed pipeline corridor is provided in Section 4.2 of Volume 2. A more detailed description of the pipeline corridor and selection process is provided in Section 2.8 of Volume 4A.

This section provides an overview of the selection process for the proposed pipeline corridor, including a discussion of how environmental, socio-economic, Aboriginal engagement, stakeholder consultation and other factors influenced pipeline corridor selection. While the proposed pipeline will generally require a construction right-of-way of 45 m, a 150 m corridor was selected to define the boundaries of the environmental resource surveys, landowner contacts and other survey needs.

This section also describes the site selection for permanent facilities such as terminals, pump stations (including access roads and power lines) and mainline block valves, as well as the site selection process for temporary facilities used during construction, such as staging and stockpile sites, equipment storage sites, construction office sites, construction work camps, work areas for trenchless watercourse crossings, temporary access roads, borrow pits and log decks.

4.1 Overview of Corridor Selection Process

This subsection provides a summary of the TMEP corridor selection process. Throughout this subsection, the abbreviation “KP” refers to “Kilometre Posts”, approximately 1 km apart, along the existing TMPL easement or right-of-way (also known as Line 1 in Volumes 2 and 4), while the abbreviation “RK” refers to “Reference Kilometres”, approximately 1 km apart along the proposed pipeline corridor (also known as Line 2 in Volumes 2 and 4). The reader is also directed to view Figure 4.1-1 for general reference to KPs and RKs and the preliminary photomosaic Environmental Alignment Sheets at a scale of 1:15,000 in Alberta and 1:10,000 in BC that are provided in Volume 6E.

Early in the Project planning process, Trans Mountain decided to maximize usage of the existing TMPL 18 m wide right-of-way to the greatest extent practical to reduce environmental and socio-economic effects and facilitate efficient pipeline operations. The existing TMPL pipeline has been operating safely for more than 60 years and its location is well known to local TMPL operations crews, landowners, surface management agencies and local emergency responders. By constructing on or adjacent to the existing TMPL right-of-way, the number of new or additional landowners is reduced. Furthermore, landowners and surface management agencies are accustomed to the presence of a pipeline, and understand the types of land practices that maintain pipeline safety. The environmental and socio-economic effects can generally be reduced by constructing beside the existing TMPL right-of-way since it is possible to share temporary workspace that has been previously affected by construction, thereby minimizing the width of land and amount of vegetation to be disturbed. Similar benefits occur where the new pipeline is planned beside rights-of-way of other linear facilities, including other pipelines, power lines, highways, roads, railways, fiber optic transmission systems (FOTS) and other utilities. Finally, access to the right-of-way and power lines to the pump stations are already established, reducing the need to create additional disturbance for ancillary facilities.

Following detailed field surveys as described in Section 2.8 of Volume 4A, it was determined that, while it was possible to construct on or adjacent to the existing TMPL right-of-way for approximately two thirds of the TMEP distance (see note in Section 4.3), it was not possible in all cases due to engineering, constructability, geotechnical, environmental, socio-economic, Aboriginal interests or other reasons. At these locations, a number of potential alternative corridors were examined. Major alternative corridors that were considered but rejected are described in Section 4.2. Selected alternative corridors involving major deviations from the existing TMPL right-of-way worthy of a more detailed evaluation are also described in Section 4.2. The proposed pipeline corridor is summarized in Section 4.3.

4.2 Environmental, Socio-Economic and Associated Factors Considered in Pipeline Corridor Selection

Environmental, socio-economic, Aboriginal engagement, stakeholder consultation and other factors relating to pipeline corridor selection are discussed from east to west in the direction of pipeline flow. In general, the factors influencing selection of the proposed pipeline corridor are more complex in BC than Alberta. The bulk of the Rocky Mountains on the continental divide were crossed by the TMX Anchor Loop Project constructed in 2008, however, the proposed pipeline corridor must still cross several interior mountain ranges before entering the rich agricultural land and urban development in the Lower Mainland. A large portion of the urban development in the Lower Mainland, Kamloops and elsewhere has occurred after construction of TMPL in 1953. Likewise, the provincial parks potentially encountered by the Project have been established since TMPL was built.

4.2.1 Edmonton to Hinton Segment

This pipeline segment is characterized by dense urban development in the east, graduating to scattered country residential development, agricultural land and forests in the west.

Given that the TMPL Edmonton Terminal is on the east side of the City of Edmonton, it is difficult for a pipeline heading to the West Coast to avoid traversing the city. Trans Mountain examined three alternative corridors through Edmonton, each requiring a crossing of the North Saskatchewan River, the primary environmental feature in the area. The original TMPL 18 m right-of-way bypassed the then southern limits of the city, but 60 years of urban growth have caused the city boundaries to move many kilometres further south (see Plate 1 at the end of Section 4.2). Rather than run adjacent to hundreds of residential properties, Trans Mountain chose to take advantage of the Edmonton Transportation/Utility Corridor (TUC) established by the Province of Alberta in the 1970s. Accordingly, a major deviation from the existing TMPL right-of-way to the south takes place in the first 45 km of pipeline corridor. Final placement of TMEP within the TUC will be as directed by Alberta Infrastructure, the TUC administrator. Trans Mountain also examined the TUC around the north side of Edmonton but rejected that corridor when Alberta Infrastructure advised that a private land in-holding currently blocks the north TUC to future pipelines.

The proposed pipeline corridor rejoins the TMPL right-of-way west of Edmonton, following it through less developed areas of the City of Spruce Grove and the Town of Stony Plain before entering more rural landscapes and scattered country residential development in Parkland County. The existing TMPL right-of-way traverses Wabamun Lake Provincial Park for several kilometres. Wabamun Lake Provincial Park is located on the north shore of Wabamun Lake and was established as a provincial park in 1955 after construction of TMPL in 1953. The current proposed pipeline corridor passes north of the park; however, recent discussions with Alberta Tourism, Parks and Recreation indicate that it may be possible to follow TMPL through the park. During consultation, public stakeholders were open to routing the alternative corridor through the park, as it is in a utility corridor and adjacent to Highway 16. From an environmental and socio-economic perspective, crossing through the park parallel to the existing TMPL right-of-way is preferable because it is shorter, parallels an existing right-of-way, has fewer highway and road crossings and affects fewer private landowners.

Further west, the proposed pipeline corridor generally follows the TMPL right-of-way, crossing the Pembina River and McLeod River close to or beside the existing right-of-way towards the Town of Edson, which is bypassed immediately to the south. For the remainder of the length in Alberta, the proposed pipeline corridor generally follows the TMPL right-of-way with one main exception. Since the existing TMPL right-of-way passes through the middle of the Town of Hinton for 10.7 km, crossing adjacent to a number of residential and other private properties including a golf course, an improvement was made to follow a proposed new Highway 16 bypass that avoids the developed part of the town to the south. The proposed pipeline corridor then rejoins the TMPL right-of-way and eventually connects to the previously looped section of TMPL at the Hinton Pump Station.

4.2.2 Hargreaves to Darfield Segment

This pipeline segment is characterized by mountainous forested terrain alternating with dispersed rural residential and agricultural parcels in narrow mountain river valleys.

Commencing at Hargreaves Trap Site on the west side of Mount Robson Provincial Park and the western flank of the Rocky Mountains, the proposed pipeline corridor generally follows the TMPL right-of-way through the Fraser River valley except for a deviation to avoid Rearguard Falls Provincial Park and a crossing of the Fraser River west of the existing Rearguard Pump Station. Crossing the Fraser River east of Rearguard Pump Station is unavoidable, however, a dual crossing will be installed to avoid crossing the park and the Fraser River at a second location. The proposed pipeline corridor then rejoins the TMPL right-of-way, crossing over a height of land to enter the Rocky Mountain Trench. The Village of Valemount is bypassed to the west. Further south, the proposed pipeline corridor follows the existing TMPL right-of-way through successive narrow mountain valleys occupied by Camp Creek and the Albreda River, respectively.

As it continues to follow the existing TMPL right-of-way in a southerly direction, the proposed pipeline corridor enters the North Thompson River valley, which it generally follows for several hundred kilometres as far as the City of Kamloops. In the upper reaches of the valley, the TMPL right-of-way crosses the North Thompson River five times in less than 4 km. One crossing of the North Thompson River is unavoidable, however, an alternative corridor with reduced effects on watercourse crossings was sought by conducting field reconnaissance and gathering readily available resource information (see Figure 4.2-1 and Table 4.2-1). Following a study of four alternative corridors, the East Alternative is preferred since it: crosses the North Thompson River only once; crosses the least amount of Riparian Reserve Zone, Old Growth Management Area and critical moose winter range; is relatively short; has the fewest highway crossings; and avoids French's Hill, a known rapid earth slide hazard. For these reasons, the proposed pipeline corridor deviates from the TMPL right-of way to incorporate the East Alternative which parallels a nearby BC Hydro high voltage transmission line and forestry road for approximately 15 km.

The proposed pipeline corridor continues to generally follow the existing TMPL right-of-way, descending the narrow, forested North Thompson River valley towards the Community of Blue River, entering the Interior Plateau. At Blue River, the proposed pipeline corridor is located immediately west of the community adjacent to the existing TMPL right-of-way and passes through the existing Blue River Pump Station. An alternative corridor from Blue River to the District of Clearwater was investigated. It would have involved: deviating from the North Thompson River valley; bypassing Blue River Pump Station; ascending 800 m up a steep hill; dropping into the upper reaches of the Raft River watershed; and then paralleling the Raft River to rejoin the TMPL right-of-way at Clearwater. Although 15% shorter, this alternative was rejected since it would encounter unacceptable pipe hydraulics and open up new corridor in habitat for a *Species at Risk Act* (*SARA*)-listed species – the Groundhog Mountain Caribou herd. South of Blue River, the proposed pipeline corridor continues to generally follow the existing TMPL right-of-way in the North Thompson River valley, except for an easterly deviation south of Froth Creek to avoid potential slope instability issues along Highway 5 at a place locally known as Messiter Hill. For the most part, the eastern deviation follows existing forestry roads, cut blocks and a BC Hydro high voltage transmission line. Further on, the proposed pipeline corridor rejoins the TMPL right-of-way as far south as Finn Creek Provincial Park.

Finn Creek Provincial Park is a Class A Park designated in 1996. Since it was uncertain whether BC Parks would permit a second pipeline in the park, Trans Mountain examined alternative corridors, both in the field and using readily available information sources (see Figure 4.2-2 and Table 4.2-2). Three alternatives were studied and evaluated from an environmental and socio-economic perspective. It was concluded that, assuming BC Parks approval, the TMPL Trenchless Alternative is preferred because it is short and involves a trenchless crossing of both Finn Creek and the northern tip of the park. If a trenchless crossing proves not feasible following further geotechnical field investigations, and assuming BC Parks approval, a conventional crossing of the park is preferred because it is the shortest alternative, parallels an existing right-of-way, avoids crossing an unnamed creek and does not involve clearing a new corridor to the east. BC Parks recently approved Trans Mountain's Stage 1 request to proceed to a Stage 2 application in the BC Parks boundary adjustment process.

Further south, the proposed pipeline corridor continues following the existing TMPL right-of-way through the widening North Thompson River valley, passing by the communities of Avola, Vavenby and the District of Clearwater before encountering two portions of the North Thompson River Provincial Park, a Class A Provincial Park designated in 1967. The northern portion of the park and the Clearwater River crossing is unavoidable whereas there is an alternative to avoid the southern portion of the park to the west. Two alternative corridors were studied and evaluated from an environmental and socio-economic perspective (see Figure 4.2-3 and Table 4.2-3). It was concluded that, assuming BC Parks approval, the TMPL Alternative through the park is preferable because it is shorter, avoids highway crossings and encounters fewer private parcels. The current proposed pipeline corridor passes west of the park, although BC Parks recently approved Trans Mountain's Stage 1 request to proceed to a Stage 2 application in the BC Parks boundary adjustment process. The Stage 2 application would also incorporate the northern portion of the park described above.

Further south, the proposed pipeline corridor continues along the North Thompson River valley in the Interior Plateau, following the TMPL right-of-way as far south as Darfield Pump Station.

CONSTRUCTABILITY AND COST		
Constructability	TMPL Alternative is slightly hummocky requiring additional extra work space in park for grade cuts.	West Alternative crosses to the west side of Highway 5 to avoid North Thompson River Provincial Park and passes through terrain equivalent to the TMPL Alternative before crossing back to the east side of Highway 5 to rejoin the TMPL corridor.
Estimated Cost ($ millions)	$3.1	$4.2

4.2.3 Black Pines to Hope Segment

This pipeline segment is characterized by rolling grasslands in the vicinity of Kamloops and Merritt in the north, graduating to forested and mountainous terrain in the south.

From the location of the proposed Black Pines Pump Station (see Section 4.4) in the Interior Plateau, the proposed pipeline corridor follows the TMPL right-of-way on the west side of the lower North Thompson River valley, which now averages 2 km in width, becoming increasingly settled and agricultural. The community of Westsyde in the City of Kamloops has recently expanded along a broad terrace of the river, encroaching on the TMPL right-of-way (see Plate 2). Lac du Bois Grassland Protected Area is located immediately west of Westsyde. The protected area was first established in 1996 after TMPL was constructed and additional lands were added through a designated expansion in 2013. These additions overlap the existing TMPL right-of-way at two short locations north of Westsyde and at a longer location (1.5 km) in the Batchelor Hills area further south, which is unavoidable. During the consultation process, strong community support was expressed by some stakeholders for a corridor west of Westsyde through the protected area following a FOTS right-of-way (see Plate 3), while others raised concerns about effects of the Project on the protected area. Both alternative corridors were studied and evaluated from an environmental and socio-economic perspective (see Figure 4.2-4 and Table 4.2-4). It was concluded that, assuming BC Parks approval, the West Alternative is preferred because it crosses slightly fewer watercourses, considerably fewer private parcels and avoids the community of Westsyde. BC Parks recently approved Trans Mountain's Stage 1 request to proceed to a Stage 2 application in the BC Parks boundary adjustment process. The Stage 2 application would also incorporate the 2013 additional lands described above.

The proposed pipeline corridor then rejoins the TMPL right-of-way and crosses the Thompson River just east of the Kamloops Airport, ascending the south slope of the river valley to eventually connect to the Kamloops Pump Station on the south side of Highway 5.

The proposed pipeline corridor generally follows the existing TMPL right-of-way across a semi-forested upland plateau from Kamloops to Merritt, with three possible exceptions. The first is a jog to the west on the property of the proposed KGHM Ajax Mining Inc. copper and gold mine to avoid Jacko Lake and a narrow valley, where there is insufficient room to install a second pipeline. Further south, the existing TMPL right-of-way crosses the corners of two IRs north of Merritt (Zoht 5 and Zoht 4), where minor deviations avoiding the IRs are being considered in addition to following beside TMPL through the IRs.

The proposed pipeline corridor follows the existing TMPL right-of-way through the eastern limits of the City of Merritt in the Nicola River valley, cutting the northwest corner of the Joeyaska IR No. 2. A minor deviation avoiding the IR to the north and west is also being considered. Further south, the proposed pipeline corridor continues to follow the existing TMPL right-of-way up the Coldwater River valley, traversing Coldwater IR No. 1 for 7 km.

Based on correspondence from the Coldwater Indian Band, several alternative corridors east and west of the IR were studied and evaluated from an environmental and socio-economic perspective (see Figure 4.2-5 and Table 4.2-5). The currently proposed pipeline corridor is the East Corridor, although the Modified East Alternative is also under consideration. From an environmental and socio-economic perspective, and with the Coldwater Indian Band's approval, the preferred corridor would switch to the TMPL Modified Alternative Corridor as it: is the shortest; generally parallels an existing right-of-way; crosses the fewest watercourses; encounters the least amount of bedrock; and crosses the least amount of designated Ungulate Winter Range habitat.

Further south, the proposed pipeline corridor rejoins the existing TMPL right-of-way ascending the narrowing Coldwater River valley to just south of Kingsvale Pump Station. The terrain becomes increasingly mountainous as the proposed pipeline corridor extends further south through the Hozameen Range of the Cascade Mountains. From Kingsvale Pump Station, the proposed pipeline corridor deviates from the existing TMPL right-of-way several times to parallel the Spectra gas pipeline right-of-way which generally parallels the existing TMPL right-of-way in the Coldwater River valley area. These deviations are generally undertaken to take advantage of better terrain, to reduce the number of Coldwater River crossings or to minimize the length in the Riparian Reserve Zone.

In the upper reaches of the Coldwater River valley, the existing TMPL right-of-way is in close proximity to Coldwater River Provincial Park for 2 km, crosses the divide into the Coquihalla Summit Recreation Area and continues southwards through the Coquihalla Lakes area, over a 185 m "Jump Off" into the narrow gorge locally known as Coquihalla Canyon, eventually crossing the Coquihalla River 13 times in less than 20 km (see Plate 4). There is limited working room in Coquihalla Canyon for a second pipeline and constructability is a concern. An alternative corridor with reduced effects on water crossings was sought. After considerable field reconnaissance, a West Alternative Corridor was identified which follows a combination of a Spectra gas pipeline right-of-way, a FOTS right-of-way and the right-of-way of the relatively recently constructed Coquihalla Highway (Highway 5) through the Boston Bar Creek drainage west of Coquihalla Canyon. Both alternative corridors were studied and evaluated from an environmental and socio-economic perspective (see Figure 4.2-6 and Table 4.2-6). It was concluded that the West Alternative is preferred because it: entails 1 river crossing as opposed to 16; crosses considerably less terrain with high natural hazard potential; has considerably less length through the Riparian Reserve Zone, Old Growth Management Areas, and designated Ungulate Winter Range; avoids Coldwater River Provincial Park and crosses slightly less of the Coquihalla Summit Recreation Area. The two corridors rejoin where Boston Bar Creek flows into the Coquihalla River.

From this point to the District of Hope, the proposed pipeline corridor follows the narrow and steep Coquihalla River valley beside one of the existing rights-of-way occupied either by TMPL, Coquihalla Highway, Spectra or FOTS, depending upon the most constructible terrain and other factors. For example, the existing TMPL right-of-way traverses Coquihalla River Provincial Park for 3 km, whereas the proposed pipeline corridor avoids the park altogether. Once in the District of Hope, the proposed pipeline corridor generally follows the existing TMPL or the Spectra rights-of-way and, at the request of the Union Bar Indian Band, avoids the Kawkawa Lake IR No. 16. The proposed pipeline corridor continues west, crossing the Coquihalla River upstream of its confluence with the Fraser River and entering Hope Pump Station.

4.2.4 Hope to Burnaby Segment

West of the District of Hope, the proposed pipeline corridor generally follows the existing TMPL and Highway 1 (Trans-Canada Highway) rights-of-way in the narrow strip of land between the Fraser River and the Skagit Range of the Cascade Mountains. The remainder of the proposed pipeline corridor traverses the rich agricultural lands of the Lower Mainland of BC, which becomes increasingly urbanized from the Fraser Valley Regional District west to Metro Vancouver. Most of the agricultural lands are part of the provincial Agricultural Land Reserve. The proposed pipeline corridor generally follows the existing TMPL right-of-way unless otherwise specifically mentioned.

The proposed pipeline corridor continues west into the Lower Mainland, although minor deviations are being considered to avoid Ohamil IR No. 1, Peters IR No. 1A and Popkum IR No. 1. East of the City of Chilliwack, the proposed pipeline corridor crosses to the north side of the Trans-Canada Highway to parallel a BC Hydro power line in order to avoid a crossing of Bridal Veil Falls Provincial Park and Popkum IR No. 2. A small portion of Cheam Lake Wetland Regional Park is crossed for approximately 100 m, although in response to considerable opposition from the public and Fraser Valley Regional District, minor deviations are being considered in this area to avoid the park.

Further west, the proposed pipeline corridor passes through the City of Chilliwack, with minor deviations being considered to avoid crossing Grass IR No. 15 and Tzeachten IR No. 13. The Vedder River is the major watercourse crossed in the Chilliwack area. Further west, the proposed pipeline corridor enters the City of Abbotsford, crossing the Sumas River and surrounding agricultural Sumas Prairie before ascending the forested south flank of Sumas Mountain. The existing TMPL right-of-way provides for a branchline to access TMPL's Sumas Terminal. On the west side of Sumas Mountain, the proposed pipeline corridor crosses increasingly urbanized areas and a golf course in the vicinity of Clayburn. Towards the western end of the City of Abbotsford, the proposed pipeline corridor crosses the Matsqui Main IR No. 2, although a minor deviation is being considered to the south. The proposed pipeline corridor then enters the Township of Langley and continues along the existing TMPL right-of-way until the vicinity of the Salmon River valley south of Fort Langley. From this point onwards to the Fraser River crossing, urbanization in Langley and the City of Surrey has encroached considerably on the existing TMPL right-of-way in the past 60 years, making contiguous looping extremely difficult. For this reason an alternative pipeline corridor was sought. Trans Mountain chose to take advantage of the existing

Canadian National Railway Company (CN) right-of-way and new South Fraser Perimeter Road corridor on the south side of the Fraser River. Accordingly, the proposed pipeline corridor leaves the existing TMPL right-of-way near a golf course and heads north on new corridor a short distance across farmland in the Salmon River valley before reaching the CN right-of-way. Minor deviations in the Salmon River area are being considered to follow property lines, a second golf course and avoid a local natural area further north if possible before joining the CN right-of-way. From this point, the proposed pipeline corridor turns west, paralleling the CN right-of-way and later the South Fraser Perimeter Road right-of-way in a westerly direction through Langley and Surrey to the crossing location of the Fraser River near the Port Mann Bridge. The proposed pipeline corridor traverses the edge of the Surrey Bend Regional Park for about 3 km, although a minor deviation is being considered to reduce this length by taking advantage of surplus land released from the recently constructed South Fraser Perimeter Road project.

Two primary locations are being considered to cross the main stem of the Fraser River between the cities of Surrey and Coquitlam using horizontal directional drilling (HDD), a trenchless method of construction (see Plate 5). Currently, the proposed pipeline corridor is located approximately 500 m east of the existing TMPL pipeline, but an alternative location is being considered on the east side of the Port Mann Bridge. On the north side of the Fraser River, urbanization in the cities of Coquitlam and Burnaby has encroached considerably on the existing TMPL right-of-way in the past 60 years to make contiguous looping extremely difficult (see Plate 6). The proposed pipeline corridor follows the Lougheed Highway, although a deviation is being considered to traverse existing industrial lands and railway easements within the Brunette River Conservation Area. Both the proposed pipeline corridor and the deviation eventually connect to TMPL's Burnaby Terminal via other city streets.

4.2.5 Burnaby to Westridge Segment

From the Burnaby Terminal to the Westridge Marine Terminal on Burrard Inlet, urbanization in the City of Burnaby has encroached considerably on the existing TMPL right-of-way in the past 60 years to make contiguous looping with twin 762 mm (NPS 30) OD buried delivery lines extremely difficult. The proposed pipeline corridor follows alongside Burnaby Mountain Parkway, Hastings Street, and Cliff Avenue before turning east into TMPL's Westridge Marine Terminal. Other more direct alternatives involving partial or total trenchless (HDD or tunnel) methods of construction are also under consideration.

Plate 2 Existing TMPL right-of-way (shown in yellow) encroached by urban development through the community of Westsyde.

Plate 3 Existing FOTS right-of-way within Lac Du Bois Grasslands Protected Area.

Plate 4 Existing TMPL right-of-way within Coquihalla Canyon in foreground and proposed corridor beside Coquihalla Highway and FOTS in mid-ground.

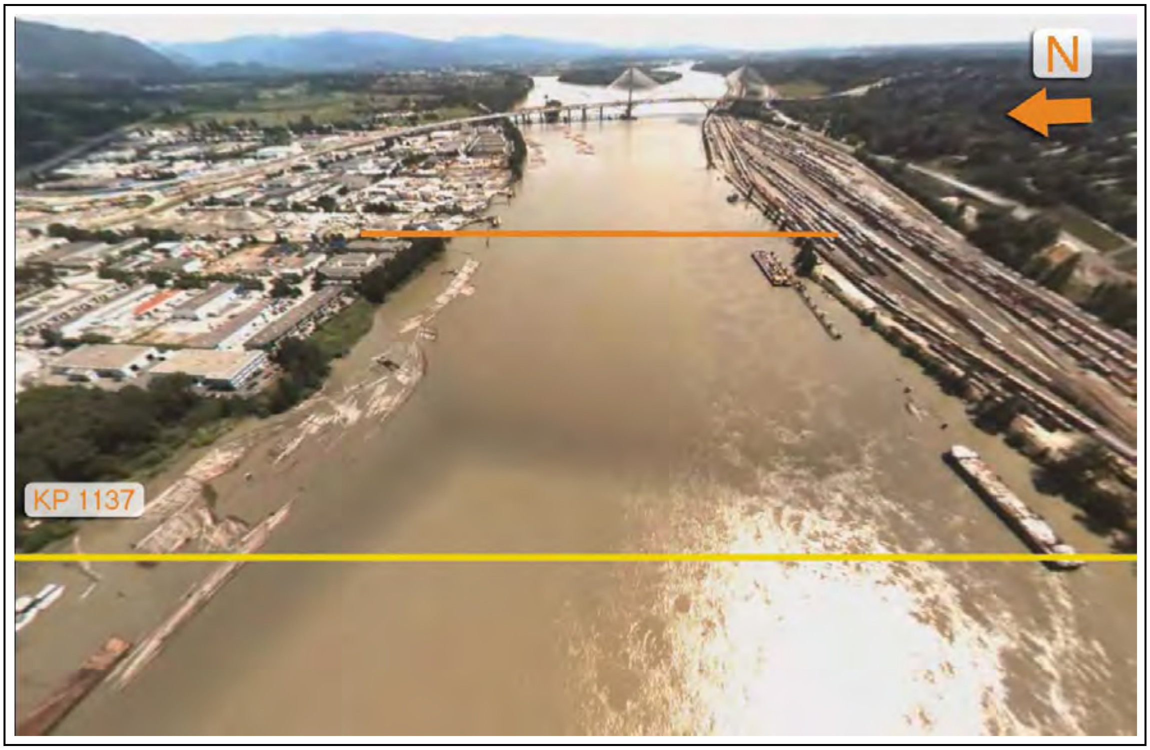

Plate 5 Overlooking the existing crossing of the Fraser River looking east with existing TMPL right-of-way (shown in yellow) in foreground, proposed pipeline corridor (shown in orange) in mid-ground and Port Mann Bridge in background.

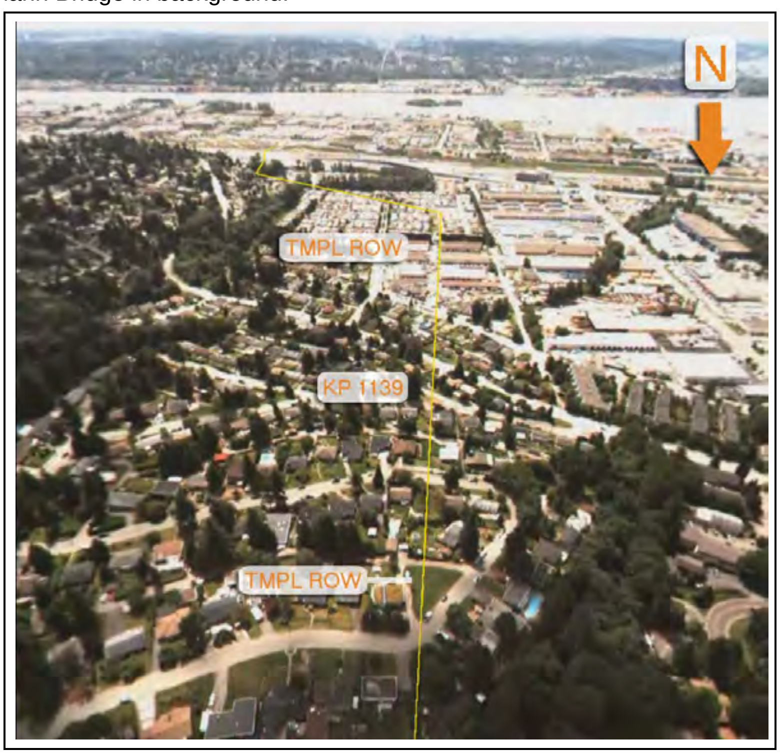

Plate 6 Looking south along the existing TMPL right-of-way (shown in yellow) encroached by urban development in the City of Coquitlam, BC.

4.3 Proposed Pipeline Corridor

Every effort has been made to follow the existing TMPL right-of-way or other existing rights-of-way as much as possible. Of a total length of 990 km, the proposed pipeline corridor follows the existing TMPL right-of-way for 662 km (67%) and the rights-of-way of other linear facilities for 220 km (22%) for a total parallel length of 882 km (89%). The remaining 108 km (11%) are on new corridor. The proposed pipeline corridor is shown on all the mapping in the remainder of this document and the preliminary Environmental Alignment Sheets provided in Volume 6E.

Note that Volumes 5A and 5B utilize preliminary results of parallel calculations, whereas the other volumes in the NEB application utilize final numbers. As a result, there is a slight discrepancy. The final percentages of TMPL parallel, other parallel and new corridor are 73%, 17% and 10%, respectively.

For purposes of this application, it was necessary to identify a proposed pipeline corridor to focus environmental and other studies. The environmental and socio-economic assessment was conducted by overlaying the proposed pipeline corridor on the project environmental setting and making predictions about environmental effects based on available information, known mitigation practices and professional judgment. It is recognized that additional landowner, stakeholder, environmental, socio-economic, geotechnical, and other information will come forward that will lead to improvements in the location of the pipeline corridor. In addition, the pipeline routing specialists are continuing to refine the proposed 150 m corridor and narrow it down to a pipeline construction right-of-way. These improvements will adopt the routing criteria, strategies and guidelines described in Volume 4A, Section 2.8 without jeopardizing pipeline safety and security. Where corridor modifications occur, additional studies will be completed to confirm predictions and implement appropriate mitigation from the EPPs. No fundamental change in the overall conclusion of no significant adverse effects is anticipated. Additional information is provided in Section 9.0 of Volumes 5A and 5B.

4.4 Permanent Facility Site Selection

4.4.1 Introduction

The TMEP is a loop of the existing 1,150 km TMPL system from Edmonton to Burnaby that has been in operation since 1953. As well as the looping of the pipeline, several new or expanded facilities (*e.g.,* pump stations, storage tanks, etc.) are required to efficiently operate the pipeline system. An overview of the general facility site selection objectives/criteria and the proposed facility sites is provided in Section 4 of Volume 2. A detailed description of the facilities associated with the TMEP is provided in Sections 3.3, 3.4 and 3.5 of Volume 4A.

New and/or expanded permanent facilities are required for the successful operations of the pipeline component of the Project.

The permanent facilities associated with the Project include the following.

- Installing 23 new sending and receiving traps (16 on TMPL and TMEP), for in-line inspection tools at 9 existing sites and one new site.
- Adding 35 new pumping units at 12 locations (*i.e.,* 11 existing and 1 new pump station sites).
- Reactivating the existing Niton Pump Station that has been maintained in a deactivated state.
- Constructing 20 new tanks located at the terminals near Edmonton (5). Sumas (1) and Burnaby (14), preceded by demolition of two existing tanks near Edmonton (1) and Burnaby (1), for a net total of 18 tanks added to the system.
- Constructing one new dock complex, with a total of three Aframax-capable berths, as well as a utility dock (for tugs, boom deployment vessels, and emergency response vessels and equipment) at Westridge Marine Terminal, followed by the deactivation and demolition of the existing berth.

This subsection describes the site selection criteria and site selection process used by the Project team to choose the sites where permanent facility sites will be located.

4.4.2 Site Selection Criteria

Edmonton, Sumas and Burnaby Terminals

The Project includes the addition of storage tanks at the existing Edmonton Terminal, Sumas Terminal and Burnaby Terminal locations. Additional booster pumps and metering facilities are also proposed for the Edmonton and Burnaby facilities. Site selection for these new facilities is primarily focused on minimizing environmental and land use disturbance by utilizing existing facility locations. The proposed expansion of the existing terminal locations is based on the following site selection criteria.

- Maximize safety of personnel and the public during construction and operations.
- Reduce environmental effects and new disturbances.
- Limit effects on terrestrial vegetation and wildlife habitat.
- Accommodate facility expansion within existing property boundaries.
- Integrate the expansion works with existing operations.
- Ensure existing infrastructure (*e.g.,* access roads) are in place and suitable for Project needs.
- Minimize issues related to undesirable topography or terrain instability.
- Avoid culturally sensitive areas.
- Avoid conflicting land uses and encroachment upon residences/communities.
- Accommodate Aboriginal community, landowner, regulatory authorities and other stakeholder feedback, to the extent feasible.

All work associated with the Project to be conducted at Edmonton, Sumas and Burnaby terminals will be conducted within the footprint of the existing industrial sites on Trans Mountain-owned lands. No new land will be acquired for the expansion of existing facilities or the installation of new facilities at the terminal locations.

Westridge Marine Terminal

The Project includes an expansion of the existing tanker loading facilities at the Westridge Marine Terminal. Site selection is primarily focused on reducing environmental and land use disturbance by utilizing existing facility locations. Expansion of the existing dock facility is based on the following criteria.

- Maximize safety of personnel and the public during construction and operations.
- Provide the highest level of navigational safety, both for vessels berthing at Westridge Marine Terminal and for other vessels transiting the inlet or at one of the four anchorages nearby.
- Provide three Aframax capable berths, allowing capacity for vessels to wait for cargo or transit windows to reduce pressure.
- Allow the existing dock to remain in service during the construction of the new dock complex, and specifically until the new Berth 1 can be commissioned.
- Reduce the overall footprint and the effect to the community views.
- Eliminate the deep-water dredging and reduce the amount of dredging for the foreshore expansion.
- Minimal storm surge effect is expected at the existing dock site. Available public information suggests that the hazard from a tsunami is very low for the area.
- Reduce environmental effects and new disturbances.

- Reduce effects to terrestrial vegetation and wildlife habitat by using existing disturbed lands to the extent feasible.
- Avoid parks and recreational areas.
- Accommodate land-based component of facility expansion within existing property boundaries.
- Proximity of existing facilities to nearby existing infrastructure (*e.g.,* access road, electric power supply).
- Avoid culturally sensitive areas.
- Avoid conflicting land uses and encroachment upon residences/communities.
- Accommodate Aboriginal community, landowner, regulatory authorities and other stakeholder feedback to the extent feasible.

Pump Stations

Pump station sites are largely selected according to the hydraulic pressure requirements of the pipelines. Pump station location was determined following selection criteria designed to respond to construction, operational, environmental and land use constraints. Factors affecting the selection of pump station sites included the pipeline diameter, pipeline operating pressures, the hydraulic and elevation profile and the type of liquid being transported (high or low viscosity). New pump stations to be located on a previously undisturbed site (*i.e.,* Black Pines) were typically provided a siting range of +2 km downstream or -1 km upstream along the existing TMPL right-of-way, centred on the hydraulic optimum. Once the optimal hydraulic points were selected, the following site selection criteria were considered in the final placement of the pump stations.

- Locate the site on existing or former pump station sites or on lands owned by Trans Mountain. Where this was not possible, the following criteria were used.
  - Consult landowners to seek voluntary agreement to acquire the necessary lands with respect to surrounding land use and constraints.
  - Reduce disturbance by utilizing previously disturbed sites, where practical.
  - Locate site near existing infrastructure (*e.g.,* access roads, power lines), to the extent feasible.
  - Locate the site within less environmentally sensitive areas, to the extent feasible.
  - Avoid areas of terrain instability.
  - Avoid wetlands and riparian areas.
  - Avoid conflicting land uses and encroachment upon residences and communities, wherever practical.
  - Avoid known archaeological, heritage and traditional land use sites.
  - Accommodate Aboriginal community, landowner and regulatory authorities and other stakeholder feedback to the extent feasible.

Trans Mountain first identified lands that had been previously disturbed for other uses. In all instances, with the exception of Black Pines Pump Station, existing sites that have been previously used as pump stations or other company uses were selected for development of new pump stations by the Project.

Mainline Block Valves

Site selection criteria for mainline block valves will include:

- engineering and operations requirements;
- meet industry codes and standards, at a minimum;
- avoid wetlands and other sensitive environmental features;
- locate in vicinity of existing access roads and power supplies, if feasible;
- avoid steep slopes, unstable terrain and poorly drained areas; and
- avoid being immediately adjacent to major watercourses.

4.4.3 Terminal Site Selection

Edmonton Terminal

All new and upgraded facilities associated with the Edmonton Terminal will be constructed on Trans Mountain-owned lands on a previously disturbed, industrial area.

Sumas Terminal

The site for the new tank to be constructed at the Sumas Terminal is located to the north of the existing tanks on Trans Mountain-owned land. The land where the new facilities will be installed has been previously disturbed. There may be a small amount of clearing required along the north fenceline of the terminal site to make space available for an access road and to relocate an existing power line.

To make space available for the new tank, an existing containment berm will be dismantled and the area graded level to support the foundation for the new tank. A new containment berm will be constructed before the new tank is put into operation. The new containment berm will be comprised of the materials from the existing berm as well as the graded materials, provided these materials are acceptable for such a use (*i.e.,* non-porous).

A power line that is currently located on the north edge of the existing cleared area may be relocated to make space available for the new tank. Electrical facilities will not be upgraded as part of this development.

Burnaby Terminal

All lands required for the new and upgraded facilities associated with the Burnaby Terminal are owned by Trans Mountain. Some onsite riparian vegetation associated with several drainage channels that traverse the facility site will need to be cleared.

Westridge Marine Terminal

All new and upgraded facilities associated with the on-shore portion of the Westridge Marine Terminal will be located within the existing disturbed area on land that is owned by Trans Mountain. Additional reclaimed foreshore lands will be required to provide the space required for the new and upgraded facilities associated with the off-shore component of the Westridge Marine Terminal.

4.4.4 Pump Station Site Selection

Edmonton Pump Station

All new and upgraded facilities associated with the Edmonton Pump Station will be constructed on Trans Mountain-owned lands within a previously disturbed, industrial area.

Gainford Pump Station

All lands required for this new pump station are owned by Trans Mountain. Some of the lands are previously undisturbed by industrial developments and remain intact with a native tree cover. The new pump station will be located to the northwest of the existing pump station facilities. The size of the station operating area associated with the Gainford Pump Station will be increased by approximately 0.6 ha on lands that are owned by Trans Mountain.

Niton Pump Station

The two deactivated pumping units associated with TMPL will be reactivated as part of TMEP. No new lands will be acquired for this aspect of the Project. All works planned for the Niton Pump Station will occur within the fenced site of the existing pump station on land that is owned by Trans Mountain. There will be no new facilities constructed at the Niton Pump Station associated with TMEP.

Wolf Pump Station

The expansion of the facilities at Wolf Pump Station will be to the west of the existing facilities on previously disturbed lands that are owned by Trans Mountain. A new pump building will be located adjacent to the existing pump building. The existing electrical infrastructure will be reused for TMEP operations. No new disturbance to previously undisturbed lands will be necessary at Wolf Pump Station.

Edson Pump Station

All land required for the planned upgrades and expansion of the Edson Pump Station is owned by Trans Mountain. All of the land required by the Project has been previously disturbed.

Hinton Pump Station

A new pump station will be built immediately adjacent to the existing Hinton Pump Station. Additional new lands will have to be acquired by Trans Mountain for the new pump station. The existing fence line will be expanded to the west by approximately 35 m, increasing the station operating area by approximately 0.3 ha.

Jasper Pump Station

All construction work to be conducted at the Jasper Pump Station will be located within the current fenced area of the existing pump station. There will be no new disturbance of previously undisturbed lands outside of the current fenced area associated with this work. Trans Mountain will not have to expand the lease they currently hold with Parks Canada.

Rearguard Pump Station

Additional new lands will have to be acquired by Trans Mountain for the development required at the Rearguard Pump Station. The existing fence line associated with this station will be expanded to the east by approximately 100 m, which will increase the station operating area by approximately 0.7 ha. The area that will be developed for this new pump station is relatively flat and has been previously disturbed.

Blue River Pump Station

All construction activities planned for the Blue River Pump Station will take place on previously disturbed lands that are owned by Trans Mountain. A new pump building will be located adjacent to the existing pump building. The existing electrical infrastructure will be reused for TMEP operations.

Blackpool Pump Station

All lands required for the planned expansion and upgrades associated with the Blackpool Pump Station are owned by Trans Mountain. All of the lands have been previously disturbed.

Darfield Pump Station

Trans Mountain will need to acquire a small amount of additional land (approximately 0.07 ha) located outside of the current fence line of the Darfield Pump Station to the north in order to accommodate the new scraper facilities to be installed at this site. The lands located to the north of the existing pump station are currently being used for agricultural purposes. Negotiations to acquire these lands by voluntary agreement are currently underway.

Black Pines Pump Station

The Black Pines Pump Station is the only new pump station location required for the Project that is not associated with a currently existing pump station. Pumping facilities for both TMPL and TMEP will be installed at Black Pines.

The general location for this pump station was selected based on the hydraulic optimum that considers the operating pressures and throughput of product in both TMPL and TMEP pipelines. The general location was identified along a 2 km length of the pipeline between KP 784 and KP 786 of the existing pipeline system. A field reconnaissance was conducted in December 2012 to further refine the location of the pump station to increase the distance from the nearest residences while keeping the station within the range of the identified hydraulic preference. The general terrain of the land was also considered during this reconnaissance to ensure the selected site was not located on steep slopes, in a wetland or close to waterbodies.

The preliminary site selected for the pump station is located at RK 811.8 (KP 784.6). This location is tree covered with mature coniferous trees (see Plate 7). The surface materials where the pump station would be located consist of a debris fan. Therefore, further geotechnical assessments will be required at this site to determine the optimum location for the station as well as to determine appropriate mitigation measures to protect the facilities from a potential debris flow during the operations phase of the Project. The current surface of the site is sloped, which would require grading to level the surface for construction and operations of the pump stations.

Plate 7 Aerial view of the proposed Black Pines Pump Station Site (May 27, 2013).

It is anticipated that an area of 150 m x 150 m will be required for the construction of the pump station and associated facilities (*e.g.,* sending/receiving traps). This area would generally be located to the west of the current Trans Mountain right-of-way, with the exception of the containment pond, which would be located east of the existing right-of-way. Final layout of the proposed pump station will be determined during detailed engineering design.

The lands that have been identified for this new pump station are currently privately owned. Trans Mountain will seek to acquire the lands needed for the construction and operation of the Black Pines Pump Station. Trans Mountain is currently negotiating with the landowners to acquire the land required for the Black Pines Pump Station.

Black Pines Power Line Route Selection Process

A search for existing power lines with a suitable voltage rating that is required for the Black Pines Pump Station was conducted after the preliminary site for the pump station was identified. A suitable existing power line was identified on the east side of Highway 5, which is to the east of the Black Pines Pump Station site (Figure 4.4-1).

A desktop assessment of existing surface encumbrances (*e.g.,* residences, farm buildings, etc.) and terrain and landscape features in the area surrounding the preliminary pump station site and the existing power line was conducted. Representatives of Trans Mountain and TERA conducted a field reconnaissance of the Black Pines area in December 2012 to verify the results of the desktop assessment.

A representative of Trans Mountain met with BC Hydro in February 2013 to discuss the potential to 'tap' into the existing power line at one of three potential locations along the line and to discuss high level routing considerations for the new power line. BC Hydro indicated that a 'tap' into this power line would be possible and that their preference would be to avoid routing the new power line across an island in the North Thompson River.

The preliminary power line route was selected to:

- reduce overall route length;
- reduce the number of bends in the line;
- avoid close proximity to residences; and
- avoid routing over an island in the North Thompson River.

With these considerations in mind, a preliminary route option was selected to the north of the island identified as a routing constraint by BC Hydro. The route crosses the North Thompson River and then turns to the south on the west side of Westsyde Road where it intersects with the north boundary of the preliminary Black Pines Pump Station site.

A route option to the south of the island in the North Thompson River was not considered due to a higher density in residences on both the east and west sides of the North Thompson River.

A representative of Trans Mountain presented the preliminary 'tap' in location and route option to BC Hydro on May 13, 2013. BC Hydro endorsed both the route and the 'tap' location on May 31, 2013.

Access Road Route Selection Process

Depending on the final site selected for the pump station, a suitable location to construct the access road intersecting with Westsyde Road will be chosen. The terrain as well as the line-of-sight along Westsyde Road will be considered when selecting the access road required for the Black Pines Pump Station. Given the close proximity of the preferred site for the Black Pines Pump Station to Westsyde Road, the access road will be short (*i.e.,* less than 100 m).

201311_MAP_TERA_ESA_00493_Rev0.mxd

Kamloops Pump Station

All new and upgraded facilities to be constructed at the Kamloops Pump Station associated with TMEP will be constructed on lands that are owned by Trans Mountain on previously disturbed, industrial land.

Kingsvale Pump Station

A new pump station and electrical substation will be constructed immediately adjacent to the existing Kingsvale Pump Station. The power line that currently feeds the existing pump station is undersized for the added load associated with the new pump station. Therefore, a new 138 kV power line, approximately 23.5 km in length, will also be required to provide electricity to this pump station.

The land required for the new pump station and electrical substation to be installed at Kingsvale is owned by Trans Mountain. Some new clearing and grading will be required to create a level working surface for the construction of the new facilities at Kingsvale Pump Station.

Kingsvale Power Line Route Selection Process

A search for existing power lines with suitable voltage rating as required for the Kingsvale Pump Station that are located in the vicinity of the Kingsvale Pump Station was conducted. A suitable power line exists on the east side of Highway 5A, which is to the east of the Kingsvale Pump Station site (Figure 4.4-2).

A desktop assessment of existing surface encumbrances (*e.g.,* residences, farm buildings, etc.) as well as terrain and landscape features in the area surrounding the study area between the Kingsvale Pump Station and the existing power line was conducted. Representatives of Trans Mountain and TERA conducted a field reconnaissance of the area in December 2012 to verify the results of the desktop assessment.

A representative of Trans Mountain met with BC Hydro in February 2013 to discuss the potential to 'tap' into the existing power line and to discuss high level routing considerations for the new power line. BC Hydro indicated that a 'tap' into this power line would be possible.

The preliminary power line route option was selected to:

- reduce overall route length;
- reduce the number of bends in the line;
- parallel existing linear features, to the extent practical; and
- avoid close proximity to residences.

With these considerations in mind, a preliminary route option was selected based on a desktop assessment of the area.

An aerial reconnaissance of the preliminary route option was conducted on May 27, 2013. Based on this reconnaissance several minor adjustments to the preliminary route alignment were made to avoid paralleling a drainage channel as well as steep sidehill terrain.

A representative of Trans Mountain presented the preliminary 'tap' in location and route options to BC Hydro on May 13, 2013. BC Hydro will have to approve the routing for the new power line since the selected route must meet their satisfaction from an operations perspective as well as future expansion considerations, if the selected route is located adjacent to the existing 500 kV transmission corridor. BC Hydro endorsed the selected route and the 'tap' location into the existing power line on May 31, 2013. However, BC Hydro has conducted an analysis to determine whether there will be an issue of induced current on the new power line required for the Kingsvale Pump Station. The result of the study indicated that there are no issues with the proposed route. The final route alignment for this power line will be selected during detailed design of the Project.

The Proposed Power Line Route

The proposed power line route extends to the northwest along an existing access road from the 'tap' in location to the existing power line. From here, the proposed route continues to the west of Highway 5A before turning to the southwest. The proposed route then turns to the northwest and continues westward until it nears the existing 500 kV transmission corridor approximately 8 km east of the Kingsvale Pump Station. The proposed route then turns to the west and parallels the existing 500 kV transmission line corridor with an offset of 70 m south of the southernmost conductor on the existing transmission line. After crossing to the west of Highway 5, the proposed route turns to the north following the existing TMPL right-of-way before it enters the lands where the new substation will be constructed within the Kingsvale Pump Station site.

Pressure Control Station

A pressure control station may be required on both TMPL and TMEP. It is likely that this facility would be installed at the Hope Pump Station if it is determined during detailed design that it is required for operations.

Existing access and electrical facilities for the Hope Pump Station will be sufficient for the construction and operation of the pressure control station.

The lands required for the pressure control station are owned by Trans Mountain.

Sumas Pump Station

There will be a new pumping unit installed on the 609.6 mm OD (NPS 24) pipeline heading south from the Sumas Pump Station into Washington State (*i.e.,* the Puget Sound line).

The land required for the new pumping unit to be installed at the existing Sumas Pump Station is owned by Trans Mountain and has been previously disturbed by industrial activity.

4.4.5 Mainline Block Valves Site Selection

Once the approximate locations of mainline block valves have been identified, using the criteria listed above in Section 4.3.2, the sites will be subject to an environmental assessment. Detailed environmental surveys (*e.g.,* soils, vegetation and wildlife) will be conducted, where warranted, to determine any potential environmental issues associated with these sites.

The evaluation of mainline block valve locations will be conducted as far in advance of their intended use, as practical, in order to allow adequate time to identify and evaluate any alternate sites. In the event that specific mitigation is warranted for a specific site, the measures developed will be documented in the Environmental As-Built Report (see Volume 6A). General provisions will be included in the contract documents that commit contractors to site protection/restoration measures at sites identified, evaluated and used during the construction program. Mitigation measures to be used at mainline block valve sites will be as described in Section 7.0 of Volume 5A and Volume 6B (Pipeline EPP). All applicable approvals for the mainline block valves will be acquired prior to use of the site or area. The level of mitigation measures applied will ensure that any residual environmental effects are reduced to a level that is not significant.

4.5 Temporary Facility Site Selection

4.5.1 Introduction

New and/or expanded temporary facilities will be required during the construction of the Project. The temporary facilities associated with TMEP will include:

- staging and stockpile sites;
- equipment storage sites;
- construction office sites;

- construction work camps (likely one in Alberta and two in BC);
- trenchless crossing work areas;
- shoo-flies/temporary access roads;
- borrow pits; and
- log decks.

This subsection describes the site selection criteria and site selection process that will used by the Project team to select the sites where temporary facility sites will be located.

4.5.2 Temporary Facility Site Selection Criteria

The following site selection criteria will be used to evaluate and select temporary facility sites and workspace.

- Selection of an optimal location for construction needs.
- Locate the facility in the vicinity of similar existing facilities to reduce environmental and land use disturbances.
- Locate temporary facilities that require the use of utilities at sites already serviced by roads and utilities.
- Avoidance, to the extent practical, of areas of native vegetation by maximizing the use of previously cleared or broken lands, or lands currently under industrial land use.
- Preferential selection of grassed areas over bush or wooded areas when temporary workspace is necessary on lands supporting native vegetation.
- Avoidance, to the extent practical, of known locations that provide site-specific habitat for wildlife species of concern or apply special mitigation (refer to Section 7.0 of Volume 5A).
- Avoidance, to the extent practical, of known sites that support vascular plant species of concern or apply special mitigation (refer to Section 7.0 of Volume 5A).
- Avoidance, to the extent practical, of steep slopes, organic soils and poorly-drained areas.
- Avoidance, to the extent practical, of known areas with heritage resource sites or apply special mitigation (refer to Section 7.0 of Volume 5B).
- Avoidance of locations adjacent to a conflicting land use where potential noise, dust or visual concerns could not be readily mitigated.
- Avoidance of parks and protected areas.
- Abide by requests of Aboriginal communities, landowners and regulatory authorities, to the extent feasible.

4.5.3 Temporary Facility Site Selection

The need for and the respective general location of these sites are the responsibility of the pipeline or facilities construction contractor. However, all temporary workspace and temporary facility site locations will require the approval of the Inspector(s) or qualified designate.

Once the location of temporary workspace or a temporary facility for use during construction has been identified, the sites will be assessed and, where appropriate, approved by the Inspector(s) or qualified designate. Detailed environmental surveys (*e.g.,* soils, vegetation and wildlife) will be conducted, where warranted, to determine any potential environmental issues.

The evaluation of potential temporary facility sites/workspace will be conducted as far in advance of its intended use, as practical, in order to allow an adequate time to chose and evaluate any alternate sites. In the event that specific mitigation is warranted for the site, the measures developed will be documented in the Environmental As-built Report (see Volume 6A). General provisions will be included in the contract documents that commit contractors to site protection/restoration measures at sites identified, evaluated and used during the construction program. Mitigation measures to be used at temporary facility sites and temporary work areas are described in Section 7.0 of Volume 5A and Volume 6B (Pipeline EPP). All applicable approvals for the temporary facility site or workspace will be acquired prior to use of the site or area. The level of mitigation applied will ensure that any residual environmental effects are reduced to a level that is not significant.

5.0 ENVIRONMENTAL SETTING FOR THE PIPELINE

Prior to European contact, numerous Aboriginal communities settled both the plains and woodlands of Alberta. European settlement and influence began in the late 1700s with the advent of the fur trade. When the Hudson's Bay Company relinquished control of the land in 1870s, the region was opened for settlement, resulting in expansive colonization and transformation of the land for agricultural development, which became the dominant economic activity in Alberta until the discovery of oil in the Leduc field in 1947 (Government of Alberta 2012).

Prior to European contact, BC's productive coastal region was likely one of the areas most densely inhabited by First Nations in North America. European settlement began along the south coastal regions in the late 1700s, expanding rapidly inland with the discovery of gold in the Fraser River and the Cariboo Region in the 1860s. Bustling cities, roads, railways and steamships were constructed to accommodate the influx of prospectors and merchants. By the mid-1900s, major transportation developments were undertaken to accommodate growing industries such as hydro-electric power, mining and forestry, and to connect regions and communities throughout BC (Province of BC 2012). Further information on past development of the Project area is provided in Section 8.1.

The following subsections present a summary of the environmental setting of the proposed pipeline corridor for the following elements from the NEB *Filing Manual* (NEB 2013): physical and meteorological environment; soil and soil productivity; water quality and quantity; air emissions; greenhouse gas (GHG) emissions; acoustic environment; fish and fish habitat; wetlands; vegetation; wildlife and wildlife habitat; and species at risk. The environmental setting was compiled based on the following sources.

- Geotechnical, soil, groundwater, air quality, GHG, acoustic, fish, wetland, vegetation and wildlife field studies conducted for the Project (Volumes 4A and 5C).
- Existing published literature including topographic maps, aerial photography, scientific papers and reference books, as well as municipal, provincial and federal government maps, reports, interactive websites, guides, information letters, fact sheets and databases.
- Consultation and engagement with Aboriginal communities (including Aboriginal Traditional Knowledge [ATK] and Traditional Ecological Knowledge [TEK], landowners, regulatory authorities, stakeholders and the general public).

ATK is defined as knowledge that is held by, and unique to, Aboriginal peoples. TEK is a subset of ATK that is primarily concerned with the environment. ATK and TEK have been integrated into the setting in the following subsections, where applicable, from information gathered by the Aboriginal engagement team. The inclusion of ATK and TEK is essential in understanding the overall setting of the environment.

Resource material was obtained by searching libraries, internet searches and documents from regulatory authorities. References used in the preparation of the environmental setting are cited in Section 5.14. Detailed methodology for the collection of information on existing conditions, including field studies, is provided in the applicable supporting studies in Volume 5C, with the exception of the following BGC Engineering Inc. reports, which are provided in Volume 4A: Route Physiography and Hydrology; Terrain Mapping and Geohazard Inventory; Seismic Assessment Desktop Study; and Volume 5C: Acid Rock Drainage and Metal Leaching Potential Technical Report.

This section is divided into the setting for the pipeline segments (Sections 5.1 through 5.11), proposed line facilities (Section 5.12) and the existing pipeline segments to be reactivated (Section 5.13). The potential Project-related effects and mitigation are presented in Section 7.0.

The settings for each element (a technical discipline or discrete component of the biophysical or human environment identified in the NEB *Filing Manual* [NEB 2013]) discuss existing conditions within defined spatial boundaries. Element-specific spatial boundaries are described in the subsections below.

The settings for each element discuss the existing conditions for each indicator or set of indicators selected for the element. An indicator (sometimes called Valued Ecosystem Components [VECs]) is defined as a biophysical, social or economic property or variable that society considers to be important and is assessed to predict Project-related changes and focus the impact assessment on key issues. One or more indicators are selected to describe the present and predicted future condition of an element. Societal views are understood by the assessment team through published information such as management plans and engagement with regulators, the public, Aboriginal communities and other interested groups. A summary of the indicators selected for each element is provided in Table 5.0-1. The rationales for the selection of indicators are provided in Section 7.0.

TABLE 5.0-1

SELECTED INDICATORS FOR BIOPHYSICAL ELEMENTS

Element	Indicators
Physical and Meteorological Environment	• Terrain instability. • Topographic change. • Acid generating rock.
Soil and Soil Productivity	• Soil productivity. • Soil degradation. • Bedrock and stone disposal. • Soil contamination.
Water Quality and Quantity	• Surface water quality. • Surface water quantity. • Groundwater quality. • Groundwater quantity.
Air Emissions	• Primary emissions of criteria air contaminants (CACs) (particulate matter [PM], carbon monoxide [CO], nitrous oxide [N_2O] and sulphur dioxide [SO_2]) and volatile organic compounds (VOCs) (benzene, toluene, ethylbenzene and xylene [BTEX]). • Secondary smog-related products like ozone and $PM_{2.5}$. • Hydrogen sulphide (H_2S) and mercaptans emissions (odour potential). • Fugitive emissions from pump stations (discussed in Section 6.0).
GHG Emissions	• Common GHGs such as methane (CH_4), carbon dioxide (CO_2), N_2O and sulphur hexafluoride (SF_6). • Effect of Project on climate change.
Acoustic Environment	• Sound levels. • Vibrations.
Fish and Fish Habitat	• Riparian habitat. • Instream habitat. • Fish mortality or injury. • Indicator species include: – Alberta: Arctic grayling; Athabasca rainbow trout; northern pike; bull trout; burbot; and walleye; and – BC: bull trout/Dolly Varden; Chinook salmon; coho salmon; cutthroat trout; and rainbow trout/steelhead.
Wetland Loss or Alteration	• Wetland function.
Vegetation	• Vegetation communities of concern. • Plant and lichen species of concern. • Presence of infestations of provincial weed species and other invasive non-native species identified as a concern.
Wildlife and Wildlife Habitat	• Mammals: grizzly bear; moose; woodland caribou; forest furbearers; coastal riparian small mammals; and bats. • Birds: grassland/shrub-steppe birds; mature/old forest birds; early seral forest birds; riparian and wetland birds; wood warblers; short-eared owl; rusty blackbird; flammulated owl; Lewis's woodpecker; Williamson's sapsucker; western screech-owl; great blue heron; spotted owl; bald eagle; common nighthawk; northern goshawk; and olive-sided flycatcher. • Reptiles: arid habitat snakes. • Amphibians: lentic (pond-dwelling) amphibians; and lotic (stream-dwelling) amphibians.
Species at Risk	• Fish species at risk (*i.e.*, bull trout and coho salmon). • Vegetation species at risk. • Wildlife species at risk (*i.e.*, grizzly bear, woodland caribou, short-eared owl, rusty blackbird, flammulated owl, Lewis's woodpecker, Williamson's sapsucker, western screech-owl, great blue heron [*fannini* ssp.], spotted owl, common nighthawk, northern goshawk [*laingi* ssp.] and olive-sided flycatcher).

5.1 Physical and Meteorological Environment

This subsection presents a summary of the physical and meteorological environmental setting found in the Physical Environment LSA and, where appropriate, along the proposed pipeline segments. It describes the physical, geologic and meteorological conditions documented in the Physical Environment LSA and beyond to include the nearest meteorological stations. It further describes areas of geotechnical concern identified in the Physical Environment LSA. The indicators selected for this element discussed below include terrain instability, topographic change and acid generating and metal leaching rock. The rationale for the selection of indicators is provided in Section 7.2.1. In addition, the existing climate along the proposed corridor is provided. Detailed information related to the physical environment is provided in the following reports prepared by BGC Engineering Inc.: Route Physiography and Hydrology, Terrain Mapping and Geohazard Inventory, and Seismic Assessment Desktop Study of Volume 4A; and the Acid Rock Drainage and Metal Leaching Potential Technical Report and the Soils Technical Report of Volume 5C. Furthermore, the potential Project-related effects and mitigation pertaining to physical environment are discussed in Section 7.0. Issues related to meteorological environment are discussed under Changes to the Project Caused by the Environment in Section 7.10.

The Physical Environment LSA is considered the zone of influence (ZOI) likely to be affected by terrain instability during construction and operations, consisting of a 1 km wide band generally extending from the centre of the proposed pipeline corridor and facilities (*e.g.*, 500 m on both sides of the proposed pipeline corridor centre).

5.1.1 Terrain and Topography

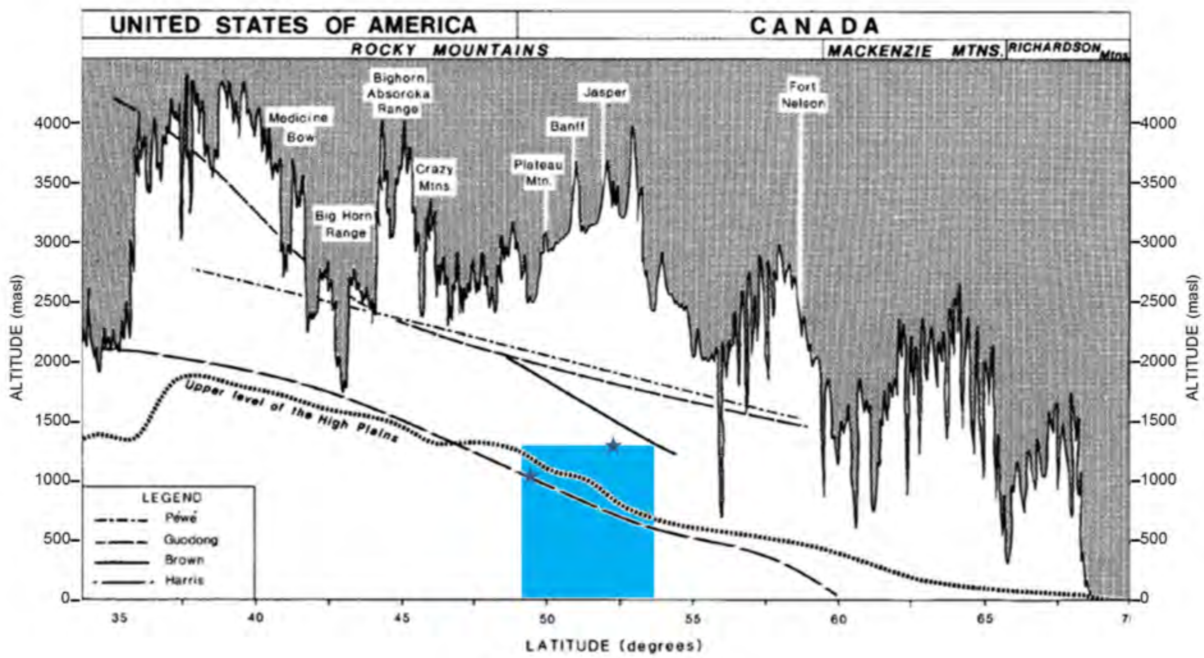
This subsection provides a summary of terrain and topographic conditions along the proposed pipeline corridor and within the Physical Environment LSA for each pipeline segment, such as physiography, bedrock, surficial geology, terrain stability (mass wasting) and wind and water erosion. In addition, a discussion of permafrost potential along the proposed pipeline corridor is provided below.

<u>Permafrost</u>

The presence or absence of permafrost is primarily temperature dependent. As such, the two primary constraints are a site's latitude and elevation. The latitude of the proposed pipeline corridor varies from 49° N near the City of Abbotsford and 53.4° N between Edson and Edmonton. Within these latitudes, the proposed pipeline corridor crosses two major mountain ranges where permafrost is known to occur at higher elevations: the Coastal Mountains; and the Rocky Mountain ranges (Harris 1986). Within these ranges, the maximum elevation of the proposed pipeline corridor is approximately 1,300 m above sea level (asl) in the Coastal Mountain range (49.6° N) and approximately 1,110 m asl in the Rocky Mountains (52.3° N).

In the 1980s, Harris summarized the distribution of permafrost based on elevation and latitude along the west coast of North America, as well as sources from other regions, as shown in Figure 5.1-1. The general trend from this figure is that at increasing latitude, the elevation boundary for permafrost presence decreases. In Figure 5.1-1, the proposed pipeline corridor is bounded within the blue box for latitude and elevation. This bounding box is located below all three lower elevation boundaries for the presence of permafrost identified for the Northern American Cordillera. Only the limits presented by Guodong (1984) fall below the elevation range of the proposed pipeline corridor; however, this data is based primarily on data from Asia and is most applicable to that geographic region.

Figure 5.1-1 Comparison of the Variation in Lower Permafrost Boundaries with Latitude for the Northern American Cordillera (Péwé, Brown and Harris) and for the Northern Hemisphere (Guodong)



Source: Harris 1986

More recently, a global permafrost distribution model was presented (Gruber 2012) that uses relationships between air temperature and the occurrence of permafrost. The model is run with high-resolution (~1 km) global elevation data and air temperatures based on the National Centre for Atmospheric Research, the National Centre for Environmental Prediction reanalysis and Climate Research Unit time series 2.0 thermal dataset for global air temperature. This data is freely available and was used within a GIS framework to determine the proximity of the proposed pipeline corridor to any potential permafrost occurrence. Based on this information, no permafrost is expected to be encountered along the proposed pipeline corridor.

Furthermore, air photos and satellite images were assessed to confirm the results from the Gruber spatial permafrost distribution model. Once more, no features were identified that would indicate the existence of permafrost along the proposed pipeline corridor.

5.1.1.1 Edmonton to Hinton Segment

The following subsections describe the physiography, bedrock, surficial geology, terrain stability (mass wasting) and wind and water erosion along the Edmonton to Hinton Segment.

<u>Physiography</u>

From east to west, the proposed pipeline corridor along the Edmonton to Hinton Segment crosses the following physiographic regions: Eastern Alberta Plains; Western Alberta Plains; Southern Alberta Uplands; and Rocky Mountains (Pettapiece 1986).

The Eastern Alberta Plains Physiographic Region (RK 0.0 to RK 128.3) is characterized by undulating plains, hummocky terrain, steep valley walls, active fluvial channels and glaciofluvial deltas (Natural Regions Committee 2006a, Pettapiece 1986). Physiographic sections crossed by the proposed pipeline corridor within this region are the Edmonton Plain (RK 0.0 to RK 5.0, RK 17.1 to RK 32.9 and RK 37.9 to RK 72.2), Cooking Lake Uplands (RK 5.0 to RK 17.1), Lac la Biche Plain – North Saskatchewan Valley

(RK 32.9 to RK 37.9) and Cherhill Uplands (RK 72.2 to RK 128.3) (Pettapiece 1986). Elevation generally rises to the west from approximately 670-800 m. Relief is generally low and arises from river incision and topographic irregularities. This area is extensively cultivated and populated to the extent that natural features may be disturbed or obscured (BGC Engineering Inc. 2013a).

The Western Alberta Plains Physiographic Region (RK 128.3 to RK 262.4) is characterized by undulating plains, less abundant hummocky terrain and incised river valleys (Natural Regions Committee 2006a, Pettapiece 1986). Within this region, the proposed pipeline corridor crosses the Drayton Plain Physiographic Section (RK 128.3 to RK 262.4) (Pettapiece 1986). Elevation increases to the west from approximately 730-980 m. Relief is low and arises from incised river valley depressions and hummocky uplands. Agricultural land use and resource exploration sites are widespread to the extent that natural features may be modified (BGC Engineering Inc. 2013a).

The Southern Alberta Uplands (RK 262.4 to RK 339.4) is characterized by hummocky terrain, rolling uplands, gently undulating terraces and incised river valleys (Natural Regions Committee 2006a, Pettapiece 1986). Within this region, the proposed pipeline corridor crosses the Western Benchlands Physiographic Section (RK 262.4 to RK 287.7) and Grande Cache Benchlands Physiographic Section (RK 287.7 to RK 339.4) (Pettapiece 1986). Elevation and relief arise from bedrock-controlled rolling to ridged hills and foothills. Elevation ranges from approximately 960-1,185 m, generally increasing to the west. Forestry and resource exploration is common in this area to the extent that natural features may be obscured (BGC Engineering Inc. 2013a).

Additional physiographic descriptions for this segment of the proposed pipeline corridor along the Edmonton to Hinton Segment are summarized by natural subregion in Table 5.1-1.

TABLE 5.1-1

PHYSIOGRAPHY OF NATURAL SUBREGIONS CROSSED BY THE EDMONTON TO HINTON SEGMENT

Natural Region	Natural Subregion	Approximate RK	Landform
Parkland	Central Parkland	RK 0 to RK 68.8	Undulating plains and hummocky uplands composed mainly of glacial till with lacustrine, fluvial and eolian inclusions.
Boreal	Dry Mixedwood	RK 68.8 to RK 145.6 RK 145.8 to RK 147.2 RK 150.7 to RK 152.1	Undulating plains and hummocky uplands composed mainly of till and considerable lacustrine deposits.
	Central Mixedwood	RK 145.6 to RK 145.8 RK 147.2 to RK 150.7 RK 152.1 to RK 169.9	Undulating plains and some hummocky uplands composed of equal proportions of till, lacustrine and fluvial deposits.
Foothills	Lower Foothills	RK 169.9 to RK 308.9 RK 311.8 to RK 319.6	Dissected plateaus and rolling uplands composed of till and considerable fluvial deposits.
Rocky Mountain	Montane	RK 308.9 to RK 311.8 RK 319.6 to RK 339.4	Valleys and foothills composed of till and considerable fluvial deposits.

Source: Natural Regions Committee 2006a

The topography along the proposed pipeline corridor is undulating to hummocky with gentle to moderate slopes. However, moderate to steep slopes may be encountered at deeply incised, major watercourse crossings, including those listed below under the terrain stability heading.

Bedrock Geology

The Eastern Alberta Plains Physiographic Region is underlain by the Horseshoe Canyon Formation and the Scollard Formation. The Horseshoe Canyon Formation (RK 0 to RK 90.6) is characterized as interbedded non-marine sandstone, siltstone, shale and numerous coal and bentonite beds (Hamblin 1998). Sandstones are soft, light-grey to greenish grey, poorly sorted and very fine to medium-grained (Hamblin 1998). Mudstones are grey-green or brown, argillaceous and bentonitic, and also carbonaceous. Units usually contain wood fragments, thin coal streaks, ironstone concretions and beds with plant and dinosaur fossils (Hamblin 1998). The Scollard Formation (RK 90.6 to RK 128.8) in the Eastern Alberta Plains consists of two units: the lower “barren” member; and the upper coal-bearing member. The lower member is characterized as thick greenish-grey shales and thin sandstones. The upper member is characterized as dark grey, bentonitic mudstones with coals (Hamblin 2010).

The Western Alberta Plains Physiographic Region is underlain by members of the Scollard and Paskapoo Formations. The Scollard Formation continues from the Eastern Alberta Plains Physiographic Region (RK 128.8 to RK 135.8) as described above. The Paskpoo Formation (RK 135.8 to RK 262.4) is a thick sequence of Palaeocene sand and siltstones. It consists of buff, medium-grained sandstone overlain by interbedded light grey soft sandy siltstone and mudstones (Dawson *et al.* 1994, Hamblin 2004). Coal seams are common in the Upper Dalehurst Member of the Paskapoo (Hamblin 2004).

The Southern Alberta Uplands Physiographic Region is underlain by the Paskapoo Formation (RK 262.4 to RK 315.5), as described above, and members of the Coalspur Formation, Brazeau Formation and Alberta Group. The Coalspur Formation (RK 315.5 to RK 322.2) of the foothills is approximately equivalent to the Scollard Formation as described above for the Eastern Alberta Plains Physiographic Region. This formation consists of the “barren” Lower Member and the coal-bearing Upper Member (Hamblin 2010). The Brazeau Formation (RK 326.1 to RK 329.9 and RK 333.1 to RK 335.9) contains interbedded greenish-grey mudstones, siltstones and fine-grained grey to greenish grey sandstone, with lesser but prominent coarser grained sandstone layers (Glass 1990). Thin coal beds, coaly shale and numerous thick bentonites occur in the upper part of the formation (Hamblin 1998). The Alberta Group (RK 329.9 to RK 339.4) is composed of dominantly dark grey, silty mudstones and a prominent middle sandstone sequence (Glass 1990).

Soil investigations and mapping along this segment were conducted in September 2006, July 2013 and from September to October 2013. Bedrock within trench depth may be encountered in shallow Bremay, shallow Dekalta, shallow Hubalta and Modeste soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

Surficial Geology

The dominant surficial materials in the Eastern Alberta Plains Physiographic Region are thick glaciolacustrine and till sediments with lesser glaciofluvial, fluvial, colluvium, eolian and bedrock outcrops (Shetsen 1990). Glaciolacustrine and till deposits overlie discontinuous pre-glacial Saskatchewan sands and gravels as well as sedimentary bedrock (Edwards *et al.* 2006). Glaciolacustrine deposits are characterized as dark sands, silts and clays with ice-rafted stones (Shetsen 1990). Wind modification of the dried glacial lake bed produced silt and sand dunes within the Edmonton area (Edwards *et al.* 2006). Glaciofluvial deposits, both pre-glacial and post-glacial, contain gravels, sands and silts. Tills are medium to moderately fine-textured and moderately calcareous (Natural Regions Committee 2006a). Localized ice-thrust moraines near Lake Wabamun comprise deformed tills and bedrock (Edwards *et al.* 2006, Shetsen 1990). Valley slopes at water crossings are variable and may consist of exposed glaciolacustrine, till, bedrock and colluvial deposits (Shetsen 1990).

Surficial material in the Western Alberta Plains Physiographic Region are till and glaciolacustrine sediments with lesser active fluvial, glaciofluvial, deltaic, eolian and ice-thrust moraine deposits (Natural Regions Committee 2006a, Roed 1975, Shetsen 1990). Glaciolacustrine units are more common in low valleys and to the west of the physiographic region. Overburden depth is variable, but generally thins to the west and on steep slopes. Tills are variable in texture depending on the ice sheet source. The Laurentide-sourced Edson Till contains few clasts and has a silty-clay matrix with very low carbonate content (Natural Regions Committee 2006a, Roed 1970, 1975). The Cordilleran-sourced Malboro Till contains a moderate amount of clasts and has a silty, sandy-clay matrix with moderate carbonate content (Roed 1970, 1975). Glaciolacustrine deposits are characterized by laminated clays, silts and sands. Inactive eolian deposits are characterized as fine-grained sand. Glaciofluvial deltas are typically cross-bedded pebbly sands with thin clays and silt beds. Active fluvial deposits include sands and gravels with minor silts. Localized ice-thrust moraines contain deformed mixes of till and bedrock.

The dominant surficial materials in the Southern Alberta Uplands Physiographic Region are tills and peat deposits, with minor glaciofluvial, active fluvial, glaciolacustrine and bedrock outcrops (Roed 1970, 1975). Surficial material thickness is variable and is influenced by topography, but generally thins to the west. Deposits are thickest along valley bottoms and thinnest along steep slopes. Colluvial deposits may be common along incised river channels and at the base of slopes. Tills are primarily classified as Obed Till, which is characterized as being very stony with a sandy clay matrix and high carbonate content (Roed 1970). Clasts within the Obed Till can be larger than 1 m in size. Lesser amounts of Edson Till, as described above, may be encountered near the proposed pipeline corridor. Meltwater channel deposits near the Athabasca River valley are characterized as well-rounded gravels and cobbles. Glaciolacustrine sediments are laminated clays, silts and sands. Active fluvial deposits comprise sands and gravels.

A description of surficial material within each physiographic region crossed by the proposed pipeline corridor is provided in Table 5.1-2. The Soils Technical Report of Volume 5C provides additional information on surface (parent) material associated with soil units identified along the proposed pipeline corridor. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

TABLE 5.1-2

SUMMARY OF SURFICIAL MATERIAL CROSSED BY THE PROPOSED PIPELINE CORRIDOR BY PHYSIOGRAPHIC REGION

Surficial Material	Intersected Length (km) by Physiographic Region		
	Eastern Alberta Plains	Western Alberta Plains	Southern Alberta Uplands
Anthropogenic	1.4	--	--
Colluvium	0.2	--	1.9
Fluvial	1.9	2.8	0.9
Glaciofluvial	10.6	15.6	9.1
Glaciolacustrine	74.8	44.1	--
Lacustrine	0.7	61.7	--
Till	37.7	11.8	61.9
Organic	2.8	--	4.0
Total	130	136	77.8

Source: BGC Engineering Inc. 2013b

Terrain Stability

The earthquake ground shaking hazard is low on lands crossed by the proposed pipeline corridor. Peak ground acceleration (PGA) at a 1:2475 annual probability of exceedance (APE) is 0.1 g or less (BGC Engineering Inc. 2013c) Several minor earthquakes (magnitude 4 or less) have been documented along the western portion of the segment (NRCan 2013a).

Debris avalanches, rock fall and slumping may occur along incised watercourses crossed by the proposed pipeline corridor, including:

- Blackmud Creek at RK 24.2;
- Whitemud Creek at RK 28.1;
- North Saskatchewan River at RK 33.5;
- Pembina River at RK 135.0;
- Wolf Creek at RK 220.6;
- McLeod River at RK 223.9;
- Little Sundance River at RK 245.2; and
- Sundance Creek at RK 248.

No recent rock avalanches were mapped along the Edmonton to Hinton Segment (BGC Engineering Inc. 2013b). Refer to the Terrain Mapping and Geohazard Inventory of Volume 4A for more detailed and site-specific information on terrain and natural hazards along the Edmonton to Hinton Segment.

Wind and Water Erosion

Soil erosion risk is a measurement of vulnerability of the soil to erosion combined with the intensity of cultivation (Alberta Agriculture and Rural Development [AARD] 2005a). AARD generally considers soil erosion risk for the agricultural areas along the segment as low, with isolated areas of low to moderate risk (AARD 2005a). Wind erosion risk, which assesses the risk of soil degradation by wind on bare, unprotected mineral soil, is generally considered negligible to low (AARD 2005b), while water erosion risk, which assesses the risk of soil degradation by water on bare, unprotected mineral soil, ranges from low to severe (AARD 2005c).

NRCan evaluates the risk of wind erosion based on the nature of local climate and vegetation. Areas with dryer, warmer climates and with sparse vegetation cover are more vulnerable to wind erosion. NRCan considers unprotected soils along the segment near Edmonton to have high wind erosion risk with high climatic sensitivity, while wind erosion risk declines further west along the segment to low wind erosion risk with low climatic sensitivity and eventually to low or negligible risk with no climatic sensitivity (NRCan 2010a).

Soil investigations along this segment identified specific soil units highly susceptible to wind or water erosion. Soil units identified as highly susceptible to wind erosion include Carvel, Elk Point, gleyed Gabriel, Hoadley, Peace Hills, Primula, Rochester, peaty Rochester, shallow Rochester, Sundace and Winterbum. Soil units identified as highly susceptible to water erosion include Angus Ridge, Carvel, Cooking Lake, Hubalta, Malmo, Modeste, Primula and Winterburn. Refer to the Soils Technical Report of Volume 5C for additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.1.1.2 Hargreaves to Darfield Segment

The following subsections describe the physiography, bedrock, surficial geology, terrain stability (mass wasting) and wind and water erosion along the Hargreaves to Darfield Segment.

Physiography

From north to south, the proposed pipeline corridor along the Hargreaves to Darfield Segment crosses the following physiographic regions: Rocky Mountains; Rocky Mountain Trench; Columbia Mountains; and Interior Plateau (Holland 1976).

The Rocky Mountains Physiographic Region (RK 489.6 to RK 502.3) is characterized by structurally-controlled, moderately wide valleys surrounded by rugged, alpine mountains featuring relict glacial landforms. Mountainsides are dissected by tributary valleys and gullies (Holland 1976). Elevation generally rises along the proposed pipeline corridor from approximately 850-1,000 m. Relief is high, as the valley floor is more than 1,500 m below adjacent mountain peaks (BGC Engineering Inc. 2013a).

The Rocky Mountain Trench Physiographic Region (RK 502.3 to RK 523.7) is characterized by flat plains, active dunes, steep slopes on the margins of the trench and hummocky to undulating terrain (Holland 1976). Elevation ranges from over 1,000 m near the proposed pipeline corridor southwest of Rearguard Falls to approximately 780 m along the trench floor. Relief is nearly 2,000 m from the peaks of the mountain ranges along the trench walls to the trench floor. The trench valley is approximately 8 km wide along the proposed pipeline corridor (BGC Engineering Inc. 2013a).

The Columbia Mountains Physiographic Region (RK 523.7 to RK 612.1) is characterized by wide U-shaped main valleys, narrow hanging steeply incised tributary valleys, rugged alpine ranges, fluvial terraces, fan and relict glacial landforms. The typical north to northwestern strike of the mountain ranges and trellis-patterned drainage systems are due to the structure of the underlying metasedimentary bedrock (Demarchi 2011, Holland 1976). The proposed pipeline corridor generally parallels Highway 5 along the valley floor. Valley floor elevation generally increases from 780 m within the Rocky Mountain Trench to 880 m near the Albreda Pump Station. From the Albreda Pump Station to the Blue River Pump

Station, the valley floor elevation decreases to 670 m. The proposed pipeline corridor at times is more than 150 m above the valley floor. Relief from valley floors to adjacent peaks ranges from 1,200-1,800 m (BGC Engineering Inc. 2013a).

The Interior Plateau Physiographic Region (RK 612.1 to RK 993.8) is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans and cones (Demarchi 2011, Holland 1976). Elevation generally decreases along the North Thompson River from 670 m to 350 m near the City of Kamloops. Local relief can be considerable in the Interior Plateau due to valley incision by large rivers, although the relief on the upper plateau itself is low (BGC Engineering Inc. 2013a).

Physiographic regions and subregions encountered by the proposed pipeline corridor along the Hargreaves to Darfield Segment are listed in Table 5.1-3.

TABLE 5.1-3

PHYSIOGRAPHIC REGIONS AND SUBREGIONS CROSSED BY THE HARGREAVES TO DARFIELD SEGMENT

Region	Subregion	Approximate RK	Landform
Rocky Mountains	Park Ranges	RK 489.6 to RK 502.3	Thick cliff-forming limestone and quartzite formations of Cambrian age form many of the mountains. Topography is extremely rugged. Mature dissection of the region has reduced inter-stream areas to narrow knife-like ridges.
Rocky Mountain Trench	Rocky Mountain Trench	RK 502.3 to RK 523.7	Along the southern half, the Rocky Mountain Trench forms a continuous, somewhat sinuous valley lying between the Columbia Mountains to the west and the Rocky Mountains to the east. This valley is occupied by the southward-flowing Canoe River and northward-flowing Fraser River. The divides between the headwaters of these rivers are low.
Columbia Mountains	Caribou Mountains	RK 523.7 to RK 542.4 RK 580 to RK 612.1	The Caribou Mountains comprise a number of longitudinal ranges trending to the northwest parallel to the strike of the underlying sedimentary rocks. Individual mountains and mountain ranges rise to high serrate peaks of heights to 3,600 m that are glacially sculptured and are separated by steep-walled glaciated valleys commonly forming a trellis pattern controlled by the underlying bedrock.
	Caribou Mountains/Monashee Mountains	RK 542.4 to RK 612.1	The high mountains of the Monashees, especially those in the northern ranges, are mostly massive and bold sharp peaks separated by deep, steep-sided valleys. Peaks above 2,400 m projected through the Pleistocene ice-sheet and were subjected to intense cirque glaciations. Lower summits were covered by ice at one stage and subsequently have been sculptured by cirque and valley glaciers to sharp peaks and sawtooth ridges. Along southern ranges at elevations below 2,100 m rounded or only moderately pointed summits prevail.
Interior Plateau	Shuswap Highland	RK 612.1 to RK 769	The Shuswap Highland consists of gentle or moderate sloping plateau areas rising from 1,500 m over 2,100 m, dissected by the Clearwater and North Thompson rivers and their tributaries into large polygonal upland tracts. The valley sides are commonly steep due to glacial erosion and the total relief is considerable while local relief in the uplands is moderate.
	Thompson Plateau	RK 736.9 to RK 769.0	The Thompson Plateau has a gently rolling upland of low relief, for the most part lying between 1,200 m and 1,500 m, but with prominences of more resistant rock rising higher. The area was occupied by Pleistocene ice and a thick mantle of drift covers bedrock over large portions. Movement of the ice over the plateau produced drumlin-like formations oriented to the south and southeast.

Source: Holland 1976

The topography along the proposed pipeline corridor ranges from gentle to moderate along valley bottoms to moderate to steep along lower slopes of incised valleys of the Fraser and North Thompson rivers and many of their tributaries.

Bedrock Geology

Bedrock lithology within the Rocky Mountain Physiographic Region is composed of the Middle Member of the Miette Group (Journeay *et al.* 2000a, Murphy 2007). This unit is composed of massive to graded, thick-bedded, feldspathic, turbitic sandstones and conglomeratic sandstones (Glass 1990).

Bedrock lithology along the eastern wall of the Rocky Mountain Trench Physiographic Region primarily consists of members of the Miette Group (Journeay *et al.* 2000a, Murphy 2007). The Upper Middle member consists of metamorphic sandstones, granule and pebble-conglomerate, siltstone and phyllite. Beneath extensive valley floor deposits, the bedrock is a mixture of: unnamed carbonates; coloured shale and dolomite; and minor quartzite (BGC Engineering Inc. 2013a).

The proposed pipeline corridor in the Columbia Mountains Physiographic Region lies within a fault-controlled valley separating the Caribou Mountains to the west and north, and the Monashee Mountains to the east and south. The dominant rock types to the west are tilted, folded and faulted sediments and metamorphic sediments of the Miette, Kaza and Horsethief Creek groups (Journeay *et al.* 2000a, Murphy 2007) and of the Shuswap Metamorphic Complex. To the east, the dominant rock types are gneisses of the Malton Gneiss Complex and metamorphic rocks of the Mica Creek Succession (Journeay *et al.* 2000a, Murphy 2007). The Miette, Kaza and Horsethief Creek groups lie within the Upper Proterozoic Windermere Supergroup. Rocks of this supergroup are dominantly coarse-grained, conglomerates and pebbly sandstones, and less common carbonates (Hein and McMechan 1994). The Miette, Kaza and Horsethief groups are composed of coarse-grained, feldspathic, pebbly sandstones and conglomerate alternating with thick argillites (clay) (Hein and McMechan 1994). The Horsethief Creek Group along the northern ridges of Mount Saint Anne predominantly contains marble (BGC Engineering Inc. 2013a).

The Shuswap Highlands Physiographic Subregion (RK 612.1 to RK 736.9) of the Interior Plateau Physiographic Region contains bedrock of the Shuswap Assemblage, Eagle Bay Assemblage and Fennel Assemblage (Journeay *et al.* 2000b,c). The Shuswap Assemblage contains gneiss and schist, with lesser amounts of amphibolite, quartzites, marbles, skarns and pegmatites. The Eagle Bay Assemblage consists predominantly of Lower Cambrian to Mississippian green schist facies, metamorphic sediments and metamorphic volcanic rocks. Within the proposed pipeline corridor, the assemblage is characterized by fine-grained sedimentary rocks, quartzite, phyllite, schist, shale, volcanic rocks, greenstone and fine-grained limestone to dolostone. The Fennel Assemblage includes the marine and sedimentary rocks of the Lower Structural Division, and the pillowed to massive metamorphic basalts of the Upper Structural Division (Journeay *et al.* 2000b).

The Thompson Plateau Physiographic Subregion (RK 736.9 to RK 769.0) of the Interior Plateau Physiographic Region is characterized predominantly by the rocks of the Quesnellia Terranne (Journeay *et al.* 2000c). The dominant bedrock units are the Kamloops Group, Harper Ranch Group, Nicola Group, unnamed olivine basalts near Brigade Hill, Ashcroft Formation, Princeton Group and Spences Bridge Group. The Kamloops Group consists of basalt and andesite breccias, tuffs and sandstones (Monger and McMillan 1989). The Harper Ranch Group consists of phyllite, volcanic sandstone, igneous rock and schist with minor carbonates. The Nicola Group consists primarily of volcanic and metamorphic sedimentary units. North of Kamloops, the Nicola Group consists of argillites, sandstones and volcaniclastic deposits (Monger and McMillan 1989). South of Kamloops, the rocks are primarily of the Eastern Volcanic Facies, which consists of alkaline breccias and tuff (Monger and McMillian 1989). West of Nicola Lake, a small portion of the Central Volcanic Facies contains intermediate pyroclastics and volcanic flows. The Ashcroft Formation consists of fine to medium-grained metamorphic sediments with minor carbonates (Monger and McMillan 1989). South of Merritt, the Nicola Group western volcanic facies consists of pyroclastics, argillites and sandstones. The Spences Bridge Group comprises undifferentiated volcanic flows and tuffs (BGC Engineering Inc. 2013a).

Soil investigations and mapping along this segment were conducted from July to August 2006 and from May to June 2013. Bedrock within trench depth may be encountered in Fox, shallow Allie, shallow Lucerne, shallow Roserim, shallow, bouldery Stukemapten and shallow Snookwa soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

Surficial Geology

Surficial geology of the Rocky Mountain Physiographic Region includes active and inactive fluvial, colluvial, till and bedrock units. Overburden depth is variable and depends on slope angle and active geomorphic processes. Generally, the surficial material is thickest in the valley bottom and thinnest along steep bedrock slopes. No publications are available regarding the texture of the surficial materials in this section of the Rocky Mountains (BGC Engineering Inc. 2013a). Generally, tills are expected to have a sandy to silty matrix with variable clast content. Fluvial sediment is expected to contain gravel, sand and boulders. Colluvium is expected to be poorly-sorted and contain sand, gravel, blocks and some silts or clays (BGC Engineering Inc. 2013a).

The dominant surficial deposits in the Rocky Mountain Trench Physiographic Region are fluvial and glaciofluvial sediments, till, colluvium and organic material. Surficial deposits on the valley floor are very thick, whereas deposits along the valley walls may be thin. Meandering rivers rework valley deposits and poorly-drained oxbow lakes, surface depressions and wetlands are scattered across the valley floor. Glaciofluvial deposits are characterized as sandy loam to gravelly, often in rolling forms. Eolian erosion of the glaciofluvial deposits has created the active sand dunes of Jackman Flats Provincial Park. Fluvial overbank deposits are characterized as fine sandy loam to silt. Tills are characterized as sandy loam matrix with variable clast content. Organic materials may contain mossy-peat, woody-peat and silts (EBA Engineering Consultants Ltd. 2003).

The dominant surficial deposits in Columbia Mountains Physiographic Region are colluvium, till, glaciofluvial, active and inactive fluvial, organic and bedrock outcrops. Valley bottoms contain glaciofluvial and active flood plain deposits. Borehole drilling at bridge crossing locations indicates the fluvial and glaciofluvial deposits may be greater than 50 m thick south of the Albreda River confluence (Seeman and Blyth 2000). Cones and fans of tributary streams and gullies are common where they intersect larger dominant valleys. Glaciolacustrine units are common in the tributary valleys of the Thompson River valley, but are not found in the main Thompson River valley south of the confluence with the Albreda River (Seemann and Blyth 2000). Glaciofluvial terraces and fans typically lie above the active flood plain. Steep bedrock slopes along valley walls are commonly mantled by till and colluvial deposits (BGC Engineering Inc. 2013a).

The dominant surficial deposits in the Shuswap Highlands Physiographic Subregion of the Interior Plateau Physiographic Region are till, active and inactive fluvial, glaciofluvial, colluvium, bedrock outcrops and glaciolacustrine (Bednarski 2009, Fulton 1984). Till deposits mantle and blanket valley walls and upland surfaces. Colluvial deposits are common along valley slopes and in fans and cones. Fluvial plains and terraces are composed of active fluvial, glaciofluvial and glaciolacustrine deposits. Overburden thickness may be thin along steep slopes and bedrock ridges, and thickest in valley bottoms (BGC Engineering Inc. 2013a). The dominant surficial deposits of the Thompson Plateau Physiographic Subregion of the Interior Plateau Physiographic Region are active and inactive fluvial, glaciofluvial, colluvium, till, bedrock and glaciolacustrine (Bednarski 2009, Fulton 1974a,b, Tipper 1971). Similar to the Shuswap Highlands Physiographic Subregion, till deposits mantle and blanket valley walls and upland surfaces, and colluvial deposits are common along valley slopes and in fans and cones. Plains and terraces are composed of active fluvial, glaciofluvial and glaciolacustrine deposits. Overburden thickness may be thin along high valley walls and ridge tops, and thickest in valley bottoms (BGC Engineering Inc. 2013a).

A description of surficial material within each physiographic region crossed by the proposed pipeline corridor is provided in Table 5.1-4. The Soils Technical Report of Volume 5C provides additional information on surface (parent) material associated with soil units identified along the proposed pipeline corridor. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

TABLE 5.1-4

Terrain Stability

The earthquake ground shaking hazard is low on lands crossed by the proposed pipeline corridor. PGA is between 0.1 g and 0.2 g at a 1:2475 Annual Probability of Exceedance (APE) (BGC Engineering Inc. 2013c). The proposed pipeline corridor crosses zone of suspected post-glacial fault activity within the Rocky Mountain trench, where the historical earthquake record shows clusters of small to moderate magnitude (up to magnitude 6) earthquakes. The largest of these include a 6 magnitude earthquake near Valemount in 1918 and a 5.6 magnitude earthquake near Prince George in 1986 (Halchuk 2009, Lamontagne *et al.* 2007). The Seismic Assessment Desktop Study of Volume 4A provides additional information along the Hargreaves to Darfield Segment, including: surface fault rupture potential; ground-motion predictions; liquefaction potential; and seismically-induced landslide potential.

Within the Rocky Mountain Trench Physiographic Region, rock fall and debris avalanches are present on upper slopes; however, none are likely to affect the proposed pipeline corridor in the valley (BGC Engineering Inc. 2013b).

Glaciofluvial materials from approximately RK 567.0 to RK 576.0 in the Columbia Mountains Physiographic Region are dominantly composed of highly erodible medium sand with silt layers. Surface erosion and shallow debris slides are common in this area. Debris flow, debris flood and/or channel erosion hazard exists on many fans. Rock fall and debris avalanche hazards are present on many steep rock and colluvium-covered slopes throughout the region, and valley fill deposits are commonly undercut by the North Thompson River, creating unstable slopes. Several large rock avalanche and slump headscarps are present on mid to upper slopes in the region, although none are thought to be currently active. The lower slopes on the west side of the North Thompson River from RK 576.0 to RK 578.0 appear to have been actively deforming in the recent past (BGC Engineering Inc. 2013b).

Within the Interior Plateau Physiographic Region, several debris avalanches are present on steep slopes near the valley bottom of the North Thompson River. Debris flows and debris floods occur on several fans along the proposed pipeline corridor. There is potential river erosion and flooding where the proposed pipeline corridor is located on the flood plain of the North Thompson River. No recent rock avalanches were mapped along the Hargreaves to Darfield Segment (BGC Engineering Inc. 2013b).

The Terrain Mapping and Geohazard Inventory of Volume 4A provides more detailed and site-specific information on terrain and natural hazards along the Hargreaves to Darfield Segment.

Wind and Water Erosion

NRCan considers unprotected soils along the northern portion of this segment as negligible and unrated, while wind erosion risk along the southern portion of this segment has low wind erosion risk with low climatic sensitivity (NRCan 2010a).

Soil investigations along this segment identified specific soil units highly susceptible to wind or water erosion. Soil units identified as highly susceptible to wind erosion include Albreta 1, bouldery Albreta 1, Albreta 2, gleyed Albreta 2, Albreta 2 overlying gravel, Alluvium, gleyed Alluvium, Blackpool, Cayenne, disturbed Cayenne, Cranberry, Fitzwilliam, Jackman, shallow Jackman, Kwikoit 1, bouldery Kwikoit 1, disturbed Kwikoit 1, Kwikoit 2, Kwikoit 2 overlying gravel, Kwikoit 3, McNomee, Roserim, bouldery Roserim, disturbed Roserim, shallow Roserim, stony Roserim, Struthers 1, bouldery Struthers 1, disturbed Struthers 1, Struthers 2, Struthers 2 overlying gravel, Stukemapten, bouldery Stukemapten, shallow bouldery Stukemapten, Snookwa, shallow Snookwa, disturbed Snookwa, Woodley and stony Woodley. Soil units identified as highly susceptible to water erosion include Albreta 1, Allie, shallow Allie, disturbed Cayenne, Exiou, Fox, Fitzwilliam, Jackman, Kwikoit 1, Kwikoit 2, Kwikoit 2 overlying gravel, Lucerne, shallow Lucerne, stony Lucerne, Stukemapten, shallow boulder Stukemapten, Snookwa, disturbed Snookwa, shallow Snookwa, Woodley and stony Woodley. Refer to the Soils Technical Report of Volume 5C for additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.1.1.3 Black Pines to Hope Segment

The following subsections describe the physiography, bedrock, surficial geology, terrain stability (mass wasting) and wind and water erosion along the Black Pines to Hope Segment.

Physiography

From north to south, the proposed pipeline corridor along the Black Pines to Hope Segment crosses the Interior Plateau and Cascade Mountains physiographic regions (Holland 1976).

The Interior Plateau Physiographic Region (RK 811.8 to RK 993.8) is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans and cones (Demarchi 2011, Holland 1976). South of Kamloops, elevation increases from 350-1,230 m before decreasing to approximately 600 m near the City of Merritt. Elevation gradually increases to 1,170 m near Coquihalla Lakes (BGC Engineering Inc. 2013a).

The Cascade Mountains Physiographic Region (RK 993.8 to RK 1043.7) is characterized by rugged mountain ranges, steeply incised tributary valleys, wide U-shaped main valleys, relict glacial landforms, terraces, fans, cones, steep slopes, fluvial plains and small basins (Demarchi 2011, Holland 1976). Elevation generally decreases from approximately 1,350 m near the Coquihalla Highway Summit to 40 m around the District of Hope. Relief in the mountainous areas of this region is high, ranging from 1,200 m near Needle Peak to nearly 1,800 m near Hope (BGC Engineering Inc. 2013a).

Physiographic regions and subregions encountered by the proposed pipeline corridor along the Black Pines to Hope Segment are listed in Table 5.1-5.

TABLE 5.1-5

PHYSIOGRAPHIC REGIONS AND SUBREGIONS CROSSED BY THE BLACK PINES TO HOPE SEGMENT

Region	Subregion	Approximate RK	Landform
Interior Plateau	Thompson Plateau	RK 811.8 to RK 993.8	The Thompson Plateau has a gently rolling upland of low relief, for the most part lying between 1,200 m and 1,500 m, but with prominences of more resistant rock rising higher. The area was occupied by Pleistocene ice and a thick mantle of drift covers bedrock over large portions. Movement of the ice over the plateau produced drumlin-like formations oriented southeasterly and southerly.
Cascade Mountains	Cascade Mountains	RK 993.8 to RK 1022.5 RK 1026.2 to RK 1043.7	The peaks and high ridges of the Cascade Mountains are serrate and exhibit the effects of intense alpine glaciation. Cirque basins are particularly noticeable on north and northeast slopes of peaks and ridges. At lower elevations between 1,800 m and 2,100 m there are rounded ridges and dome-shaped mountains which were overridden by ice at the maximum of the Cordilleran ice-sheet.
	Hozameen Range	RK 1022.5 to RK 1026.2	

Source: Holland 1976

Topography along the proposed pipeline corridor is moderate to steep as it climbs south out of the Thompson River valley onto the predominantly rolling upland terrain of the Interior Plateau Physiographic Region. South of Merritt, moderate slopes are commonly encountered along lower slopes of the Coldwater River valley and its tributaries, while steep slopes are commonly encountered along the narrow and steep Coquihalla River valley and its tributaries.

Bedrock Geology

Bedrock geology for the Interior Plateau Physiographic Region is described in Section 5.1.1.2.

The Cascade Mountains Physiographic Region is composed of folded and metamorphosed Palaeozoic and Mesozoic sedimentary and volcanic rocks intruded by granitic batholiths (Journeay *et al.* 2000c, Monger 1989). Bedrock within the Cascade Mountain Physiographic Subregion is comprised of a variety of rock types including: coarse clastics; felsic, ultramafic and mafic volcanics; mudstones, siltstones and shales; cherts; and diorite near the Coquihalla Highway Summit and Hope (BGC Engineering Inc. 2013a).

Soil investigations and mapping along this segment were conducted from late July to early September 2013. Bedrock within trench depth may be encountered in shallow Chasm, shallow Courtney, shallow Minnie, shallow Timber, shallow Tunkwa, shallow Tullee, shallow Tranquille and shallow Trapp Lake soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

Surficial Geology

Surficial geology for the Interior Plateau Physiographic Region is described in Section 5.1.1.2.

Dominant surficial deposits within valleys of the Cascade Mountains Physiographic Region are colluvium, till, active and inactive fluvial, glaciofluvial, lacustrine, organic, anthropogenic and bedrock outcrops. Overburden thickness is variable, but is generally thickest along valley floors and thinnest along steep valley walls. Fluvial and glaciofluvial deposits generally overlie eroded till and glaciolacustrine sediments along valley floors (BGC Engineering Inc. 2013a).

A description of surficial material within each physiographic region crossed by the proposed pipeline corridor is provided in Table 5.1-1. Intersected length of surficial material for the Interior Plateau Physiographic Region is provided in Table 5.1-6. The Soils Technical Report of Volume 5C provides additional information on surface (parent) material associated with soil units identified along the proposed pipeline corridor. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

TABLE 5.1-6

SUMMARY OF SURFICIAL MATERIAL CROSSED BY THE PROPOSED PIPELINE CORRIDOR BY PHYSIOGRAPHIC REGION

Surficial Material	Intersected Length (km) by Physiographic Region
	Cascade Mountains
Anthropogenic	1.0
Colluvium	46.3
Fluvial	30.6
Glaciofluvial	6.7
Till	11.3
Organic	2.8
Bedrock	0.4
Total	99.1

Source: BGC Engineering Inc. 2013b

Terrain Stability

Earthquake ground shaking hazards increase from northeast to southwest along the Black Pines to Hope Segment. PGA at a 1:2475 APE ranges from less than 0.2 g around the City of Kamloops and the City of Merritt to almost 0.3 g at the District of Hope (BGC Engineering Inc. 2013c). This segment crosses the Fraser River-Straight Creek fault zones near Hope. The Straight Creek section, south of Hope, has some evidence for Quaternary fault activity, but no such evidence is known for the Fraser River section, and no historical seismicity is associated with either section (BGC Engineering Inc. 2013c). The earthquake record contains events with magnitudes up to 7.4 in the Coast Mountains and Cascade Ranges across northwestern Washington and southwestern BC (Halchuk 2009). The Seismic Assessment Desktop Study of Volume 4A provides additional information along the Black Pines to Hope Segment, including: surface fault rupture potential; ground-motion predictions; liquefaction potential; and seismically induced landslide potential.

Within the Interior Plateau Physiographic Region, several debris avalanches are present on steep slopes near the valley bottom of the North Thompson River. Debris flows and debris floods occur on several fans along the proposed pipeline corridor. There is potential river erosion and flooding where the proposed pipeline corridor is located on the flood plain of the North Thompson River. Between the cities of Kamloops and Merritt, the proposed pipeline corridor is located on relatively stable, rolling upland terrain. South of Merrit, the proposed pipeline corridor encounters pockets of fine-textured glaciofluvial and glaciolacustrine materials that are highly erodible and subject to gully and surface erosion, as well as shallow debris slides and slumps. Steep slopes subject to shallow debris avalanches are present where down-cutting has occurred adjacent to watercourses (BGC Engineering Inc. 2013b).

Within the Cascade Mountains Physiographic Region, snow avalanches are common along the proposed pipeline corridor through the narrow and steep Coquihalla River valley. Debris flows occur on many of the fans that infill the rounded valley floor and in steeply incised watercourses. No recent rock avalanches were mapped along the Black Pines to Hope Segment (BGC Engineering Inc. 2013b).

The Terrain Mapping and Geohazard Inventory of Volume 4A provides more detailed and site-specific information on terrain and natural hazards along the Black Pines to Hope Segment.

Wind and Water Erosion

NRCan considers unprotected soils along the northern portion of this segment around the cities of Kamloops and Merritt as having low wind erosion risk with low climatic sensitivity, while soils at other areas along this segment are considered negligible and unrated (NRCan 2010a).

Soil investigations along this segment identified specific soil units highly susceptible to wind or water erosion. Soil units identified as highly susceptible to wind erosion include Andrew, Andrew 1, Cavanaugh, shallow Courtney, Glossey 1, stony Glossey 1, Glossey 2, Glossey 2 overlying gravel, Glimpse 1, Glimpse 2, Minnie, bouldery Minnie, shallow Minnie and stony Minnie. Soil units identified as highly susceptible to water erosion include Andrew, Andrew 1, Cavanaugh, Chasm, shallow Chasm, Commonage, shallow Courtney, Glossey 1, Glossey 2, Lundbom, Minnie, bouldery Minnie, shallow Minnie, stony Minnie, McQueen, stony McQueen, Mossy, Timber, shallow Timber, stony Timber, Tunkwa, shallow Tunkwa, Tullee, shallow Tullee, Tranquille, shallow Tranquille, Trapp Lake and shallow Trapp Lake. Refer to the Soils Technical Report of Volume 5C for additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.1.1.4 Hope to Burnaby and Burnaby to Westridge Segments

The following subsections describe the physiography, bedrock, surficial geology, terrain stability (mass wasting) and wind and water erosion along the Hope to Burnaby Segment.

Physiography

From east to west, the proposed pipeline corridor along the Hope to Burnaby and Burnaby to Westridge segments crosses the Cascade Mountains and Georgia Depression physiographic regions (Holland 1976).

Physiography of the Cascade Mountains Physiographic Region (RK 1043.7 to RK 1091.8) is described in Section 5.1.3.1.

The Georgia Depression Physiographic Region (RK 1091.8 to RK 1179.8 and RK 0 to RK 3.6 [Burnaby to Westridge Segment]) is characterized by a flat valley floor 10-15 km wide, steep valley walls, gently rolling uplands and ridges, gently rolling to flat lowlands of terraces and plains, and deltas (Armstrong 1984, Holland 1976). Elevation along the Fraser River valley floor generally falls from 12 m near Chilliwack to sea level at its outlet to the Pacific Ocean. However, the proposed alignment diverts from the valley floor in several places and rises over prominent topographic ridges within the Lower Mainland, including Sumas Mountain (approximately 200 m) and onto the southern side of Burnaby Mountain (approximately

150 m). Relief is variable and is controlled by the distance from the alignment to the closest valley wall (BGC Engineering Inc. 2013a).

Physiographic regions and subregions encountered by the proposed pipeline corridor along the Hope to Burnaby Segment and Burnaby to Westridge Segment are listed in Table 5.1-7.

TABLE 5.1-7

PHYSIOGRAPHIC REGIONS AND SUBREGIONS CROSSED BY THE HOPE TO BURNABY AND BURNABY TO WESTRIDGE SEGMENTS

Region	Subregion	Approximate RK	Landform
Cascade Mountains	Skagit Range	RK 1043.7 to RK 1091.8	The peaks and high ridges of the Cascade Mountains are serrate and exhibit the effects of intense alpine glaciation. Cirque basins are particularly noticeable on north and northeast slopes of peaks and ridges. At lower elevations between 1,800 m and 2,100 m there are rounded ridges and dome-shaped mountains which were overridden by ice at the maximum of the Cordilleran ice-sheet.
Georgia Depression	Fraser Lowland	RK 1091.8 to RK 1179.8 RK 0 to RK 3.6 (Burnaby to Westridge Segment)	The Fraser Lowland includes the delta area of the Fraser River, an area subject to sedimentary deposition since the late Cretaceous.

Source: Holland 1976

Topography along the proposed pipeline corridor is predominantly flat as the proposed pipeline corridor extends across the Fraser River flood plain to gentle to moderately sloping east of Chilliwack and along rolling upland areas (*e.g.*, Sumas and Burnaby mountains).

Bedrock Geology

The Cascade Mountains Physiographic Region is composed of folded and metamorphosed Paleozoic and Mesozoic sedimentary and volcanic rocks intruded by granitic batholiths (Journeay *et al.* 2000c, Monger 1989). Within the Skagit Range Physiographic Subregion, bedrock is from the Bridge River, Harrison and Chilliwack terrains. These units include: orthogneiss of the Custer Gneiss; coarse clastic units of the Princeton Group; unnamed Mesozoic quartz diorite west of Hope; medium grade schist and amphibolite of Settler Schist and Broken Formation; greenshist mafic to intermediate volcanics, phyllites, and conglomerates of the Slollicum Schist; Cenozoic granodiorite of the Mount Barr Batholith; and pelites, sandstone, conglomerates and volcanics of the Chilliwack Group (BGC Engineering Inc. 2013a).

Bedrock within the Fraser Lowland Physiographic Subregion of the Georgia Depression Physiographic Region is composed primarily of Eocene clastic rocks and units of the Harrison, Bridge River and Chilliwack terranes (Journeay *et al.* 2000c). These units include: coarse-grained clastics and volcanics of the Chilliwack Group; amphibolite and gneisses of the Vedder metamorphic complex; intermediate to felsic volcanics and volcaniclastics of the Harrison Lake formation; and extensive coarse-grained clastics and rare volcanic units of the Kitsilano Formation (BGC Engineering Inc. 2013a).

During the Surrey ESA Workshop, a participant noted the possible presence of karst in the area of the proposed pipeline corridor. However, the only area where karst lands have been documented in the Lower Mainland is in the mountains southeast of the City of Chilliwack, well outside of the Physical Environment LSA (Pike *et al.* 2010).

Soil investigations and mapping along this segment were conducted from March to April 2013. Bedrock within trench depth may be encountered in shallow Cheam and shallow Cheam 1 soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

Surficial Geology

Surficial geology for the Cascade Mountains Physiographic Region is described in Section 5.1.1.3.

The dominant surficial deposits of the Fraser Lowland Physiographic Subregion are inactive and active fluvial, lacustrine, glaciofluvial, glaciomarine, glaciolacustrine and colluvium with localized bedrock outcrops and variable anthropogenic fill. Typically, the fluvial and lacustrine deposits overlie the glaciolacustrine, glaciomarine, glaciofluvial and till deposits but these sediments may be exposed at the surface. Surficial deposits depths are variable and range from 10-300 m (Armstrong 1984).

A description of surficial material within each physiographic region crossed by the proposed pipeline corridor is provided in Table 5.1-1. Intersected length of surficial material for the Cascade Mountains Physiographic Region is provided in Table 5.1-8. The Soils Technical Report of Volume 5C provides additional information on surface (parent) material associated with soil units identified along the proposed pipeline corridor. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

TABLE 5.1-8

SUMMARY OF SURFICIAL MATERIAL CROSSED BY THE PROPOSED PIPELINE CORRIDOR BY PHYSIOGRAPHIC REGION

Surficial Material	Intersected Length (km) by Physiographic Region
	Georgia Depression
Colluvium	1.1
Fluvial	31.5
Glaciofluvial	10.2
Glaciolacustrine	0.7
Lacustrine	7.2
Till	13.6
Organic	7.9
Glaciomarine	19.4
Total	91.6

Terrain Stability

Earthquake ground shaking hazard is moderate to high within the Hope to Burnaby and Burnaby to Westridge segments. PGA at a 1:2475 APE ranges from around 0.3 g near the District of Hope to 0.5 g near the Township of Langley and the City of Surrey. The Hope to Burnaby Segment either crosses or approaches two faults with suspected post-glacial activity: the Sumas and Vedder Mountain faults, both near the City of Abbotsford. Several other faults with known or suspected post-glacial activity have been documented around the Puget Sound and Georgia Basin regions, but none approach the proposed pipeline corridor (BGC Engineering Inc. 2013c). The Seismic Assessment Desktop Study of Volume 4A provides additional information along the Hope to Burnaby and Burnaby to Westridge segments, including: surface fault rupture potential; ground-motion predictions; liquefaction potential; and seismically induced landslide potential.

West of Hope to Chilliwack, the proposed pipeline corridor is bounded between steep, rocky slopes to the south and the Fraser River to the north. Debris flows occur in many of the steep watercourses along this section and could affect the proposed pipeline corridor where it crosses the fans (BGC Engineering Inc. 2013b). From RK 1078.5 to RK 1081, the proposed pipeline corridor crosses the deposit of the Cheam Rock Avalanche, a very large catastrophic landslide which occurred approximately 5,000 years ago (Orwin *et al.* 2004).

West of the City of Chilliwack, where creeks cut down through the uplands, steep ravines are formed that are subject to shallow debris avalanches. No recent rock avalanches were mapped along the Hope to Burnaby Segment and Burnaby to Westridge Segment (BGC Engineering Inc. 2013b).

The Terrain Mapping and Geohazard Inventory of Volume 4A provides more detailed and site-specific information on terrain and natural hazards along the Hope to Burnaby and Burnaby to Westridge Segments.

Wind and Water Erosion

NRCan considers unprotected soils along the eastern portion of the Hope to Burnaby Segment as negligible and unrated, while wind erosion risk along the western portion of the segment around the cities of Chilliwack and Abbotsford is considered to have moderate wind erosion risk with low climatic sensitivity (NRCan 2010a).

Soil investigations along this segment identified specific soil units highly susceptible to wind or water erosion. Soil units identified as highly susceptible to wind erosion include Cheam, shallow Cheam, Cheam 1, bouldery Cheam 1, shallow Cheam 1, Harrison, Harrison 1, Isar, Laidlaw, Sumas, Sardis and Sunshine. Soil units identified as highly susceptible to water erosion include Cheam, shallow Cheam, Cheam 1, bouldery Cheam 1, shallow Cheam 1, Harrison 1, bouldery Kenworthy, Lonzo Creek, Ryder and Whatcom. Refer to the Soils Technical Report of Volume 5C for additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.1.2 Acid Generating and Metal Leaching Rock

BGC Engineering Inc. investigated and characterized the potential for acid rock drainage and metal leaching along the proposed pipeline corridor. The purpose of the acid rock drainage and metal leaching assessment was to identify areas with minerals that may be harmful to the environment when exposed during pipeline construction. These minerals include those that generate acid as a result of the oxidation of iron-bearing sulphur minerals such as pyrite (FeS_2), pyrrhotite (FeS) and chalcopyrite ($CuFeS_2$), and those that can leach harmful metals to the environment. Of the sites investigated during the field program, nine were considered to contain potentially acid generating material. Of these nine sites, three were classified as potentially acid generating along the proposed pipeline corridor in the Physical Environment LSA.

Site 004 is located along the Edmonton to Hinton Segment at RK 14 and consists of a poorly sorted till with rounded sandstone clasts, coal (5-10%) and shale fragments. Orange staining of coal rich layers is pervasive. No previous documentation was found with respect to acid rock drainage, metal leaching or coal deposits for this site. The extent of the coal seams is unknown and could extend for several kilometres. The acid rock drainage potential at this site is considered to be high considering the modest sulphide-S content associated with the coal fragments within the till. There is very little neutralization potential available within the till to neutralize any acid that may be generated from the coal seams.

Site 019 is located along the Hargreaves to Darfield Segment at RK 669.5. The geology of the outcrop consists of a gossanous contact zone between chlorite schist and metasediments. This outcrop is approximately 20 m high by 50 m wide. Approximately 50% of the outcrop material is metasedimentary and only 20% is gossanous. The acid rock drainage potential at this site is considered to be high considering the high sulphide-S content. Given the low neutralization potential of the surrounding material, it is uncertain if the non-potentially acid generating rock will have the potential to neutralize all of the acid generated from the potentially acid generating material.

Site 042 is located along the Black Pines to Hope Segment at RK 987.8 and consists of a very fine-grained shale/argillite. It is 100 m wide by 4 m high. The fresh surface is black/dark grey and the weathered surface is rusty brown with drusy yellow and white secondary sulphide mineralization. Sulphides observed include disseminated pyrite and pyrite stringers (5%). This site had the highest total sulphur content of all the samples, but measured sulphide content was low, as was the leachable sulphate content. Consequently, acid rock drainage potential at this site is considered to be moderate since total sulphur is dominated by non-extractable sulphur and is not likely a concern (*i.e.*, the risk of acid rock drainage is minimal).

The Acid Rock Drainage and Metal Leaching Potential Technical Report of Volume 5C provides additional information pertaining to acid rock drainage.

5.1.3 Climate

This subsection provides a summary of regional and local climate as well as climatic and atmospheric hazards along the proposed pipeline corridor for each pipeline segment. Additional meteorological data obtained from Environment Canada stations along the proposed pipeline corridor are provided in the Air Quality and Greenhouse Gas Technical Report of Volume 5C.

5.1.3.1 Edmonton to Hinton Segment

The following subsections describe regional and local climate as well as climatic and atmospheric hazards along the Edmonton to Hinton Segment.

Regional Climate

The proposed pipeline corridor crosses the Central Parkland, Dry Mixedwood and Central Mixedwood Natural Subregions to the east and the Lower Foothills and Montane Natural Subregions to the west in the Edmonton to Hinton Segment.

The average annual temperature of the Central Parkland Natural Subregion is 2.3°C. The Dry Mixedwood Natural Subregion has the warmest summers of any of the Boreal Natural Regions with an average annual temperature of 1.1°C, while the average annual temperature of the Central Mixedwood Natural Subregion is 0.2°C. The number of frost-free days per year in the Central Parkland, Dry Mixedwood and Central Mixedwood Natural Subregions averages 102, 98 and 97 days, respectively (Natural Regions Committee 2006a).

Average annual temperature of the Lower Foothills Natural Subregion is 1.8°C, while the average annual temperature of the Montane Natural Subregion is 2.3°C. The number of frost-free days per year in the Lower Foothills and Montane Natural Subregions averages 94 and 64 days, respectively (Natural Regions Committee 2006a).

As indicated in Table 5.1-9, monthly precipitation for the five natural subregions crossed by the proposed pipeline corridor generally peaks during summer months and is lowest during late fall, winter and early spring. The Lower Foothills and Montane Natural Subregions experience similar annual monthly averages of 47 mm, with the Central Parkland, Dry Mixedwood and Central Mixedwood Natural Subregions experiencing 36 mm, 37 mm and 38 mm, respectively.

TABLE 5.1-9

AVERAGE MONTHLY PRECIPITATION (MM)

Natural Subregion	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Mean Monthly
Central Parkland	21.8	15.5	19.1	21.1	44.9	78.6	83.0	60.0	42.6	16.7	1.6	21.5	36
Dry Mixedwood	25.8	19.8	20.5	20.5	41.9	75.0	80.4	63.7	42.8	23.1	4.2	24.1	37
Central Mixedwood	24.3	18.2	21.6	21.9	42.2	74.9	85.2	65.1	46.9	27.5	3.6	25.0	38
Lower Foothills	30.7	22.4	25.7	26.9	57.9	99.3	107.8	80.5	57.3	26.8	4.2	28.0	47
Montane	37.5	31.0	36.6	49.8	67.7	82.1	64.7	63.1	54.9	33.0	13.2	35.1	47

Local Climate

The meteorological data summarized in Table 5.1-10 was obtained from three Environment Canada stations along the Edmonton to Hinton Segment: the Edmonton City Centre Airport Station, located approximately 10 km northwest of RK 0.0; the Hamlet of Entwistle Station, located approximately 1.5 km north of RK 133; and the Town of Edson Station, located approximately 1.3 km south of RK 234 (Environment Canada 2013a).

11 Data collected from 1981 to 1992-1994.
12 Data collected from 1970/1971 to 1993/1994 and 1998/1999.
13 Data collected from 1970/1971 to 1991/1992.

Climate and Atmospheric Hazards

One major tornado was recorded in the Edmonton area on July 31, 1987. It caused 27 deaths, 600 injuries, 1,700 evacuations and $300 million in damage (NRCan 2010b). Two major hailstorms were recorded in close proximity to the Edmonton Terminal: one in 1988 that caused $48 million in damage; and one in 1901 that produced 8 cm diameter hailstones (NRCan 2010c).

5.1.3.2 Hargreaves to Darfield Segment

The following subsections describe regional and local climate as well as climatic and atmospheric hazards along the Hargreaves to Darfield Segment.

Regional Climate

The proposed pipeline corridor crosses the Interior Cedar-Hemlock (ICH) and Sub-Boreal Spruce (SBS) Biogeoclimatic (BGC) zones to the north and centre and the Interior Douglas-Fir (IDF) BGC Zone to the south along the Hargreaves to Darfield Segment.

The ICH BGC Zone has an interior, continental climate dominated by easterly moving air masses that produce cool wet winters and warm dry summers. The zone is one of the wettest in the BC interior, with a mean annual precipitation of 500-1,200 mm, 25-50% of which falls as snow. Periodic dry, high-pressure, continental air masses occasionally result in very cold winter days and very hot summer days. Mean annual temperature ranges from 2°C to 8.7°C, a range that reflects the wide latitudinal extent of the ICH. The temperature averages below 0°C for 2 to 5 months and above 10°C for 3 to 5 months of the year (Meidinger and Pojar 1991).

The SBS BGC Zone has a continental climate characterized by seasonal extremes of temperature; severe, snowy winters; relatively warm, moist and short summers; and moderate annual precipitation. In contrast to boreal climates, the sub-boreal climate is slightly less continental and, therefore, slightly warmer in January and cooler in July. Winters are shorter and the growing season is slightly longer. Mean annual temperature ranges from 1.7°C to 5°C. Average temperature is below 0°C for 4-5 months of the year, and above 10°C for 2 to 5 months. Short-term data indicate that mean annual precipitation can range from 415-1,650 mm, while data from long-term stations ranges from 440-900 mm, of which 25-50% is snow (Meidinger and Pojar 1991).

The IDF BGC Zone has a continental climate characterized by warm, dry summers, a relatively long growing season and cool winters. The main influence controlling the climate is the orographic effect created in the lee of coastal mountain ranges to the prevailing easterly flowing air. Mean annual precipitation ranges from 300-750 mm, with the exception of wetter areas where precipitation exceeds 1,000 mm. Approximately 20-50% of the precipitation falls as snow. Mean annual temperature ranges from 1.6°C to 9.5°C. The average temperature is below 0°C for 2 to 5 months and above 10°C for 3 to 5 months. Substantial moisture deficits during the growing season are common and frosts can occur at any time (Meidinger and Pojar 1991).

Local Climate

The meteorological data summarized in Table 5.1-11 was obtained from two Environment Canada stations along the Hargreaves to Darfield Segment: the Blue River Airport Station, located within 100 m of RK 612.2; and the Darfield Station, located approximately 1.8 km south of RK 769 (Environment Canada 2013a).

TABLE 5.1-11

ENVIRONMENT CANADA TEMPERATURE AND WIND DATA ALONG THE HARGREAVES TO DARFIELD SEGMENT

Measurement Parameter		Community of Blue River Airport (Station 1160899)	Darfield (Station 1162265)
Average Annual Precipitation	Rainfall (mm)	719.7[1]	372.5[1]
	Snowfall (cm)	404.4[1]	112.6[1]
Highest Average Monthly Precipitation	Rainfall (mm)	107.3 (July)[1]	54.1 (June)[1]
	Snowfall (cm)	113.5 (January)[1]	37.5 (January)[1]
Highest Recorded Daily Precipitation	Rainfall (mm)	47.4 (October 16, 2003)[2]	53.3 (August 4, 1956)[5]
	Snowfall (cm)	56.1 (January 21, 1972)[2]	33 (January 7, 1982)[5]

Climate and Atmospheric Hazards

No major tornadoes or hailstorms have been recorded in the vicinity of the Hargreaves to Darfield Segment (NRCan 2010b,c).

5.1.3.3 Black Pines to Hope Segment

The following subsections describe regional and local climate as well as climatic and atmospheric hazards along the Black Pines to Hope Segment.

Regional Climate

The proposed pipeline corridor crosses the Ponderosa Pine (PP), Bunchgrass (BG) and IDF BGC zones to the north and centre and the Montane Spruce (MS), Engelmann Spruce-Subalpine Fir (ESSF), Mountain Hemlock (MH) and Coastal Western Hemlock (CWH) BGC zones to the south along the Black Pines to Hope Segment.

The climate of the PP BGC Zone is the driest and in summer, the warmest of the forested zones in BC, influenced strongly by a pronounced rainshadow effect of coastal mountain ranges. Mean annual precipitation ranges from 280-500 mm, with 15-40% falling as snowfall. Mean annual temperature ranges from 4.8°C to 10°C. Mean monthly temperature is above 10°C for 5 to 6 months and below 0°C for 2 to 5 months. Summers are very warm, with mean July temperatures of 17°C to 22°C, while winters are typically cool with light snow cover. The hot, dry summers result in considerable moisture deficits during the growing season (Meidinger and Pojar 1991).

Similar to the PP BGC Zone, the climate of the BG BGC Zone is characterized by warm to hot, arid summers and moderately cold winters with relatively little snowfall. Severe drought in this zone restricts tree establishment and grasslands dominate. The degree of aridity corresponds to the intensity of the rainshadow effect, which is most intense in the deep, incised valleys whereby temperature tends to increase with decreasing elevation. Typically, December and January are the wettest months, while a second precipitation peak occurs in June. The driest months are usually March and April (Meidinger and Pojar 1991).

The MS BGC Zone experiences a cool, continental climate characterized by cold winters and moderately short, warm summers. Mean annual temperature is 0.5°C to 4.7°C. The average temperature is below 0°C for 5 months of the year and above 10°C for 2 to 4 months. Mean annual precipitation ranges from 380-900 mm. The growing season is sufficiently warm and dry that moisture deficits can occur, particularly in the drier subzones (Meidinger and Pojar 1991).

The ESSF BGC Zone experiences a relatively cold, moist and snowy continental climate. Growing seasons are cool and short, while winters are long and cold. According to available data mostly from southeastern BC, mean annual temperatures range from -2°C to +2°C. Mean monthly temperatures are below 0°C for 5 to 7 months and above 10°C for 2 months or less. Mean annual precipitation is highly variable within the zone, with relatively dry areas of the zone receiving 400-500 mm of precipitation and wetter areas receiving up to 2,200 mm. Most (50-70%) precipitation falls as snow and maximum snowpack ranges from 1-4 m (Meidinger and Pojar 1991).

The coastal subalpine climate of the MH BGC Zone is characterized by short, cool summers and long, cool, wet winters, with heavy snow cover for several months. Mean annual temperature ranges from 0°C to 5°C. Average monthly temperature remains below 0°C for 1 to 5 months and above 10°C for 1 to 3 months. Mean annual precipitation ranges from 1,700-5,000 mm, of which 20-70% falls as snow. The deep winter snowpack is slow to withdraw, resulting in a short growing season. Spring and summer are often relatively dry, whereas fall and winter are typically very wet (Meidinger and Pojar 1991).

The CWH BGC Zone is, on average, the rainiest BGC zone in BC. The zone typically experiences cool summers (although hot dry spells can be frequent) and mild winters. Mean annual temperature ranges from 5.2°C to 10.5°C. The mean monthly temperature is above 10°C for 4 to 6 months of the year, with a mean temperature of 0.2°C in the coldest month. Mean annual precipitation ranges from 1,000-4,400 mm (and probably more in some areas), of which less than 15% falls as snow in the south portion of the zone (Meidinger and Pojar 1991).

Local Climate

The meteorological data summarized in Table 5.1-12 was obtained from two Environment Canada stations along the Black Pines to Hope Segment: the City of Kamloops Airport Station, located within 200 m of RK 846; and the District of Hope Airport Station, located approximately 400 m north of RK 1049.5 (Environment Canada 2013a).

TABLE 5.1-12

ENVIRONMENT CANADA TEMPERATURE AND WIND DATA ALONG THE BLACK PINES TO HOPE SEGMENT

Measurement Parameter		City of Kamloops Airport (Station 1163780)	District of Hope Airport (Station 1113540)
Average Annual Precipitation	Rainfall (mm)	224.3[1]	1,955.2[5]

Climate and Atmospheric Hazards

No major tornadoes or hailstorms have been recorded in the vicinity of the Black Pines to Hope Segment (NRCan 2010b,c).

5.1.3.4 Hope to Burnaby and Burnaby to Westridge Segments

The following subsections describe regional and local climate as well as climatic and atmospheric hazards along the Hope to Burnaby and Burnaby to Westridge segments.

Regional Climate

The entire length of the Hope to Burnaby and Burnaby to Westridge segments are located within the CWH BGC Zone discussed in Section 5.1.3.3.

Local Climate

The meteorological data summarized in Table 5.1-13 was obtained from two Environment Canada stations along the Hope to Burnaby and Burnaby to Westridge segments: the City of Chilliwack Station, located within 5 km north of RK 1095; and the City of Burnaby Simon Fraser University Station, located approximately 1 km northeast of RK 1180.2 (Environment Canada 2013a).

TABLE 5.1-13

ENVIRONMENT CANADA TEMPERATURE AND WIND DATA ALONG THE HOPE TO BURNABY AND BURNABY TO WESTRIDGE SEGMENTS

Measurement Parameter		City of Chilliwack (Station 1101530)	City of Burnaby Simon Fraser University (Station 1101158)
Average Annual Precipitation	Rainfall (mm)	1,582.2[1]	1,920.7[4]
	Snowfall (cm)	85.3[1]	89.3[4]
Highest Average Monthly Precipitation	Rainfall (mm)	272.7 (November)[1]	303.6 (November)[4]
	Snowfall (cm)	24.3 (December)[1]	29 (December)[4]
Highest Recorded Daily Precipitation	Rainfall (mm)	122.6 (December 13, 1979)[2]	171.5 (January 18, 1968)[5]
	Snowfall (cm)	66.8 (November 16, 1996)[2]	50 (December 21, 1996)[5]
Average Yearly Temperature (°C)		10.8[1]	9.6[6]
Average Warmest Month (°C)		18.8 (July)[1]	17.2 (August)[6]
Average Coolest Month (°C)		3.3 (January)[1]	2.9 (December)[6]
Highest Recorded Temperature (°C)		38 (July 21, 2006)[3]	34.5 (September 3, 1988)[5]
Lowest Recorded Temperature (°C)		-21.7 (December 29, 1968)[3]	-19.4 (December 29, 1968)[5]
Average Annual Hourly Wind Speed (km/h)		No data	No data
Highest Recorder Hourly Wind Speed (km/h)		No data	No data
Highest Recorded Wind Gusts (km/h)		No data	No data

2 Data collected from 1979/1980 to 2006/2007.
3 Data collected from 1881/1896 to 2006/2007.
4 Data collected from 1981 to 2005-2007.
5 Data collected from 1965/1966 to 2006/2007.
6 Data collected from 1981/1982 to 2006/2007.

Climate and Atmospheric Hazards

No major tornadoes or hailstorms have been recorded in the vicinity of the Hope to Burnaby and Burnaby to Westridge segments (NRCan 2010b,c).

5.2 Soil and Soil Productivity

This subsection presents a summary of the soil landscapes and characteristics encountered along the proposed pipeline corridor and in the Soil LSA. The indicators selected for this element discussed below include soil productivity, soil degradation, bedrock and stone disposal, and soil contamination. The rationale for the selection of indicators is provided in Section 7.2.2. Locations of soil types encountered along the proposed pipeline corridor are identified on the Environmental Alignment Sheets (Volume 6E).

Mentiga Pedology Consultants Ltd. (Mentiga) was commissioned by TERA on behalf of Trans Mountain to conduct soil surveys within the proposed pipeline corridor where new buried pipeline is proposed. Much of the proposed pipeline corridor had been previously surveyed for Trans Mountain by Mentiga in 2006. Soil investigations in those surveys were to a depth of 1.7-2.1 m. Pertinent soils information from the previous soil surveys was utilized in this study. Additional soil investigations were conducted by Mentiga from March to October 2013. Detailed information on the known soils encountered by the proposed pipeline corridor is provided in the Soils Technical Report of Volume 5C. The potential Project-related effects and mitigation pertaining to soil and soil productivity are discussed in Section 7.2.2.

The Soil LSA is considered the ZOI likely to be affected by direct disturbance generally consisting of a 1 km wide band from the centre of the proposed pipeline corridor and facilities (*e.g.*, 500 m on both sides of the proposed pipeline corridor centre).

5.2.1 Soil Productivity

5.2.1.1 General Soil Characteristics

<u>Edmonton to Hinton Segment</u>

This segment of the proposed pipeline corridor is located in an agricultural area and primarily encounters previously disturbed soils. Chernozems and Luvisols are the dominant soil orders encountered along this segment of the proposed pipeline corridor (Natural Regions Committee 2006a).

Orthic Black Chernozems are typically associated with grasslands and open woodlands in the Central Parkland Natural Subregion. Solonetzic soils occupy approximately 15% of the central low-relief plain, in this natural subregion, with a further 20-30% of soils having Solonetzic properties. Forested areas commonly have Orthic Dark Gray Chernozem and Dark Gray Luvisolic soils. Humic and Orthic Gleysols are the most common soil types associated with wetlands (Natural Regions Committee 2006a).

Typical soils in the Dry Mixedwood Natural Subregion are Orthic Gray Luvisols under moderately well-drained aspen forests. Dark Gray Luvisols dominate in cultivated areas. Brunisols and weakly developed Gray Luvisols occur on sandy glaciofluvial or eolian deposits. Organic soils underlying wetlands are usually Terric Mesisols, while Fibric Mesisols are associated with poor fens and bogs. Peaty and Orthic Gleysols are also common wetland soils (Natural Regions Committee 2006a).

The Central Mixedwood Natural Subregion is dominated by Gray Luvisols, and Dystric and Eutric Brunisols are associated with coarse-textured sands that occupy approximately 10% of the area. Mesisols are the dominant Organic soils occurring under fens and bogs, with Terric subgroups commonly occurring. Fibric Mesisols, Fibrisols and sometimes Cryosols are associated with bogs (Natural Regions Committee 2006a).

Orthic Gray Luvisolic soils dominate the Lower Foothills Natural Subregion on the medium and fine-textured materials of the uplands. They are accompanied by Brunisolic subgroups, particularly at higher elevations. Brunisolic Gray Luvisols and Dystric Brunisols are typical of sandy terrain, and Eutric Brunisols and Regosols are often associated with calcareous, recently deposited eolian and fluvial materials. The wetland organic deposits associated with poor to rich fens are mainly Mesisols. Orthic and Peaty Gleysols often occur adjacent to wetlands and are more common in the gently undulating areas (Natural Regions Committee 2006a).

Orthic Black Chernozems are typical in the Montane Natural Subregion under grasslands with Orthic Dark Gray Chernozems becoming dominant in wooded areas. On more moist northern slopes and at higher elevations, Gray Luvisols are prevalent. Eutric Brunisols are the dominant soil in valleys on fluvial and glaciofluvial deposits. Gleysols and Organic soils are typically associated with fens (Natural Regions Committee 2006a).

<u>Hargreaves to Darfield, Black Pines to Hope, Hope to Burnaby and Burnaby to Westridge Segments</u>

The proposed pipeline corridor in BC encounters mountainous, rural, urban and agricultural areas. Luvisols and Podzols are the dominant soil orders encountered along the segments of the proposed pipeline corridor in BC (Valentine *et al.* 1978).

The Hargreaves to Darfield Segment is dominated by Lithic, Eutric Brunisolic, Humo-Ferric Podzolic and Gray Luvisolic soils. The Black Pines to Hope Segment encounters primarily Gray Luvisolic, Brown Chernozemic, Eutric Brunisolic and Humo-Ferric Podzolic soils. The Hope to Burnaby Segment is dominated by Humo-Ferric Podzolic and Humic Gleysolic soils. The Burnaby to Westridge Segment mainly consists of Humic Gleysolic soils (Valentine *et al.* 1978).

Brunisolic soils are formed under forest and generally have a brownish-coloured Bm horizon (*i.e.*, middle mineral horizon slightly altered by hydrolysis, oxidation or solution, or all three to give a change in colour or structure, or both). A Bm horizon may develop in materials of any colour, which vary in texture from gravel to clay. Brunisolic soils include some that are calcareous to the surface and very slightly weathered, and others that are strongly acid and apparently weathered. Most Brunisolic soils are well to imperfectly-drained. They occur in a wide range of climatic and vegetative environments, including Boreal Forest, mixed forest, shrubs and grass (Agriculture and Agri-Food Canada 1998).

Soils of the Podzolic order have B horizons (*i.e.*, middle mineral horizons) in which the dominant accumulated product is amorphous material composed mainly of humified organic matter. Podzolic soils typically occur in coarse to medium-textured, acid parent materials, under forest or heath vegetation in cool to very cold humid to perhumid climates. However, minor areas of Podzolic soils also occur in wet, sandy sites in areas of sub-humid climate. Other Podzolic soils have formed in parent materials that were once calcareous (Agriculture and Agri-Food Canada 1998).

Luvisolic soils generally have light-coloured, eluvial horizons and have illuvial B horizons in which silicate clay has accumulated. These soils develop characteristically in well to imperfectly-drained sites, in sandy loam to clay, base-saturated parent materials under forest vegetation in subhumid to humid, mild to very cold climates. Some Luvisolic soils also occur in acid parent materials and in forest-grassland transition zones (Agriculture and Agri-Food Canada 1998).

Chernozemic soils are typically well to imperfectly-drained and have surface horizons darkened by the accumulation of organic matter from the decomposition of serophytic or mesophytic grasses and forbs representative of grassland communities or of grassland-forest communities with associated shrubs and forbs (Agriculture and Agri-Food Canada 1998).

Soils of the Gleysolic order are defined on the basis of colour and mottling. These soils have a horizon or sub-horizon at least 10 cm thick, the upper boundary of which occurs within 50 cm of the mineral surface. Gleysolic soils have properties that indicate prolonged periods of intermittent or continuous saturation with water and reducint conditions during their genesis. In areas of subhumid climate, Gleysolic soils occur more commonly in shallow depressions and on level lowlands that are saturated with water every spring. In more humid areas, they may also occur on slopes and on undulating terrain (Agriculture and Agri-Food Canada 1998).

5.2.1.2 Specific Soil Characteristics

<u>Edmonton to Hinton Segment</u>

Soil investigations and mapping in this segment were conducted in September 2006, July 2013 and from September to October 2013. The soil investigation covers the White Area of Alberta from the Edmonton Terminal at RK 0.0 to the Edson Pump Station at RK 247.3. The area from the Edson Pump Station west to RK 339.4 was not investigated in the field (Green Area).

The following provides detailed descriptions of dominant and less common soil sub-groups encountered along this segment of the proposed pipeline corridor. In total, 31 soil units were described and mapped along the Edmonton to Hinton Segment. Further details on the results of the soil investigation are provided in the Soils Technical Report of Volume 5C.

Gray Luvisolic soils with little or no topsoil in forested areas and 10-25 cm of topsoil in cleared and developed fields are the dominant soils in imperfectly to well-drained upland positions of the landscape in the western and west central portions of the Edmonton to Hinton Segment. Orthic and Gleyed Gray Luvisols developed on till, glaciolacustrine and glaciofluvial materials occupy approximately 38% of the proposed pipeline corridor investigated in this segment. Colour differentiation between topsoils and subsoils in these soils is usually fair.

Dark Gray Luvisols and Gleyed Dark Gray Luvisols are the dominant soils in the central and east central portion of this segment and occupy approximately 15% of the proposed pipeline corridor investigated. These soils are generally moderately well to imperfectly-drained and developed on glaciofluvial veneers overlying till, loam to clay loam-textured till or clay-textured glaciolacustrine material. Topsoil thickness varies from 10-35 cm in cleared and developed fields and topsoils are easily distinguished from subsoils by colour.

Orthic Dark Gray Chernozems with 15-70 cm of topsoil and developed on pitted deltaic material occupy approximately 9% of the proposed pipeline corridor investigated in this segment and occur mainly west of the City of Edmonton towards the Town of Stony Plain. Topsoils are easily distinguished from subsoils by colour in these soils.

Orthic and Eluviated Black Chernozems with 14-54 cm of topsoil and developed on stone-free glaciolacustrine materials, slightly to moderately stony till as well as glaciofluvial sands occupy approximately 11% of the proposed pipeline corridor investigated in this segment and occur mainly in the City of Edmonton. Colour differentiation between topsoils and subsoils is excellent in these soils.

Substantial areas of poorly-drained Gleysolic soils occur along the proposed pipeline corridor in the White Area. A variety of Gleysolic soils developed on a variety of materials have been identified. Orthic Luvic Gleysols and Orthic Gleysols with little or no topsoil and developed on till or glaciolacustrine clays, as well as Orthic Humic Gleysols, Rego Humic Gleysols and Humic Luvic Gleysols with 10-50 cm of topsoil and developed on till, glaciolacustrine clays and loams or glaciofluvial sands are prominent throughout this segment. Some of the Gleysolic soils have a peaty surface (20-50 cm of surface peat). Very poorly-drained level to depressional areas are characterized by Terric Mesisols or Typic Mesisols developed on moss peat that exceeds a depth of 50 cm or 100 cm, respectively. These soils do not have a topsoil horizon, but occasionally they have been drained and cleared for agricultural purposes and have a surface horizon which should be considered topsoil and salvaged. Notable areas of Organic soils (Terric and Typic Mesisols) occur in the western and central portions of this segment. Most of the Organic soils have not been developed for agricultural purposes and remain in their native vegetation of black spruce and larch. Poorly-drained Gleysolic and Organic soils occupy approximately 18% of the proposed pipeline corridor in the White Area (10% Organic soils and 6% Gleysolic soils).

The soils along approximately 7% of the proposed pipeline were not investigated due to access restrictions. The classification of those soils is unknown at this time. These areas will be investigated in the field at a later date (see Section 9.0).

Land use along this segment of the proposed pipeline corridor investigated consists of: treed land (31.2%); hay (27.0%); cultivated land (16.6%); tame pasture (15.0%); treed-pasture (4.2%); hay-poor sod (0.8%); cleared, but not broken land (0.6%); and tame pasture-poor sod (0.4%). Other land uses of minor extent include disturbed land (usually industrial or residential land and includes a ball park in the Town of Edson), open water, major rivers and tree farms. Present land use is unknown on approximately 1.6% of the proposed pipeline corridor due to access restrictions. Present land use is shown on the Environmental Alignment Sheets (Volume 6E).

A search of the Geographic Land Information Management Planning System (GLIMPS) did not identify any soil-related Crown dispositions crossed by the Edmonton to Hinton Segment (Alberta Energy 2013).

Participants of the Wabamun and Hinton Community Workshops indicated local information on soils in the area including sandy soils in the Wabamun areas and eolian soils in the Hinton area.

Hargreaves to Darfield Segment

Soil investigations and mapping in this segment were conducted from July to August 2006 and from May to June 2013. The soil investigation covers the segment from Hargreaves (RK 489.6) to the Darfield Pump Station at RK 769.0.

The following provides detailed descriptions of dominant and less common soil sub-groups encountered along this segment of the proposed pipeline corridor. In total, 32 soil units were described and mapped along the Hargreaves to Darfield Segment. Further details on the results of the soil investigation are provided in the Soils Technical Report of Volume 5C.

Dystric and Eutric Brunisolic soils with little or no topsoil in forested areas and 10-25 cm of topsoil in cleared and developed fields are the dominant soils in imperfectly to rapidly-drained areas throughout this segment of the proposed pipeline corridor. The Dystric Brunisols (Orthic and Eluviated Dystric Brunisols) tend to dominate the northern and central portions while the Eutric Brunisols (Orthic and Eluviated Eutric Brunisols) occur mainly in the southern portion where dryer climatic conditions occur. The Dystric Brunisols occupy approximately 49% while the Eutric Brunisols make up approximately 29% of the proposed pipeline corridor in this segment. These soils are developed on till, colluvium, glaciolacustrine silts, eolian sands as well as the glaciofluvial sands and gravels.

Well to imperfectly-drained Orthic and Brunisolic Gray Luvisols with little or no topsoil in forested areas and 10-25 cm of topsoil in cleared and developed fields occupy approximately 12% of the proposed pipeline corridor in this segment. These soils have developed on some of the finer textured till deposits as well as some of the glaciolacustrine silt deposits. These soils are used much more frequently for agricultural production than the Brunisolic soils.

Land use along this segment of the proposed pipeline corridor investigated consists of: treed land (85.9%); tame pasture (6.6%); hay (4.7%); treed-pasture (1.0%); and cultivated land (0.2%). Disturbed land occupies approximately 1% of the proposed pipeline corridor, while major rivers and open water occupy approximately 0.3% and 0.2%, respectively. Present land use is shown on the Environmental Alignment Sheets (Volume 6E).

A search of the BC Integrated Land and Resource Registry (BC ILRR) did not identify any Crown dispositions that may be related to soil in the Hargreaves to Darfield Segment (BC Integrated Land Management Bureau [BC ILMB] 2013a).

Participants of the Valemount, Blue River and Clearwater Community Workshops provided the following local information on soils in the area: sand soils in the Valemount area; wet or very rocky soils in the Blue River area; and rocky/sandy soils around the Blackpool area.

Black Pines to Hope Segment

Soil investigations and mapping in this segment were conducted from late July to early September 2013. The soil investigation in this segment covers the area that has agricultural potential, namely the area between the proposed Black Pines Pump Station at RK 811.8 to the Coldwater River at RK 971. The area from the Coldwater River (RK 971) to the Hope Pump Station (RK 1044.1) mainly parallels Highway 5 and was not investigated in the field.

The following provides detailed descriptions of dominant and less common soil sub-groups encountered along this segment of the proposed pipeline corridor. In total, 26 soil units were described and mapped along the Black Pines to Hope Segment. Further details on the results of the soil investigation are provided in the Soils Technical Report of Volume 5C.

Eutric Brunisolic soils with little or no topsoil in forested areas and 10-25 cm of topsoil in cleared and developed fields are the dominant soils in imperfectly to rapidly-drained areas throughout the proposed pipeline corridor investigated in this segment. The Eutric Brunisols (Orthic and Eluviated Eutric Brunisols) tend to dominate areas where the coarser textured materials occur. The Eutric Brunisols occupy approximately 28% of the segment investigated and are developed on till or colluvial material as well as glaciofluvial sands and gravels. The Eutric Brunisols are rarely used for agricultural production.

Well to moderately-well drained Orthic Gray Luvisols with little or no topsoil (Ah or Ahe horizon) in forested areas and 10-15 cm of topsoil (Ap horizon) in cleared and developed fields occupy approximately 14% of the segment investigated. These soils are developed on loam to clay loam textured till deposits. The Luvisolic soils are rarely used for agricultural production.

Chernozemic soils with 8-38 cm of topsoil and developed on till, colluvial fans, glaciofluvial sands and gravel, glaciolacustrine material and recent fluvial sediments occupy approximately 36% of the segment investigated. The Dark Brown Chernozems have the greatest areal extent occupying approximately 19%, while the Brown Chernozems make up approximately 9% of the segment investigated. The remaining 8% consists of Black Chernozemic soils. Colour differentiation between topsoils and subsoils is poor to fair in the Brown Chernozemic soils, fair to good in the Dark Brown Chernozemic soils, and good in the Black Chernozemic soils. Many of the Chernozemic soils, especially those on grasslands, are used for agricultural production (mainly tame pasture, hay fields and grazing on native prairie).

Approximately 15% of the soils were not field investigated due to access restrictions and the classification of those soils is unknown at this time. No soil investigations were carried out in the Lac du Bois Grasslands Protected Area near the City of Kamloops which occupies approximately 9.4% of the proposed pipeline corridor between the proposed Black Pines Pump Station and the Coldwater River. Soils are anticipated to consist mainly of Brown or Dark Brown Chernozem soils in the Lac du Bois Grasslands Protected Area.

Land use along this segment of the proposed pipeline corridor consists of: treed land (52.8%); native prairie (19.6%); tame pasture (15.6%); treed-pasture (3.1%); hay (3.0%); and cultivated land (0.4%). Disturbed land makes up approximately 3% and major rivers make up approximately 0.4%. The present land use is unknown on approximately 2% of the proposed pipeline corridor in this segment. Present land use is shown on the Environmental Alignment Sheets (Volume 6E).

A search of the BC ILRR did not identify any Crown disposition that may be related to soil in the Black Pines to Hope Segment (BC ILMB 2013a).

Participants of the Kamloops Community Workshop noted that there is high erosion potential in the area from Whispering Pines to Darfield.

Hope to Burnaby Segment

Soil investigations and mapping in this segment were conducted from March to April 2013. The soil investigation in this segment covers the area between the Hope Pump Station located at RK 1044.1 in the District of Hope to the Village of Walnut Grove in southwestern BC located at RK 1151.5. The area from Walnut Grove (RK 1151.5) to Burnaby (RK 1180) consists mainly of residential and industrial lands with little or no agricultural potential and was not investigated in the field.

The following provides detailed descriptions of dominant and less common soil sub-groups encountered along this segment of the proposed pipeline corridor. In total, 30 soil units were described and mapped along the Hope to Burnaby Segment. Further details on the results of the soil investigation are provided in the Soils Technical Report of Volume 5C.

Poorly and very poorly drained Gleysols are the dominant soils occupying approximately 26% of the proposed pipeline pipeline corridor investigated in this segment. Topsoil thickness varies from 8-70 cm but most soil profiles have 20-35 cm of topsoil. Topsoils are easily distinguished from subsoils by colour in these soils. Rego Humic Gleysols are the dominant Gleysolic soils identified, but Orthic Humic Gleysols, Cumulic Humic Gleysols, Rego Gleysols and Orthic Gleysols were also identified. These soils are prominent on the Fraser River Lowlands where they are developed on recent fluvial and lacustrine deposits. These poorly drained soils are highly susceptible to soil compaction and rutting and a high water table can be expected during the winter months and after periods of prolonged, heavy precipitation.

Moderately well to rapidly drained uplands consist mainly of Orthic and Eluviated Dystric Brunisols, Orthic Humo-Ferric Podzols, and in the western portion, Luvic Humo-Ferric Podzols developed on colluvial material, colluvial-fluvial fan deposits, eolian veneers, till deposits and glaciomarine sediments. These soils have little or no topsoil in forested areas but may have up to 35 cm of topsoil in cleared and developed fields. The Dystric Brunisols and Podzols occupy approximately 22% of the proposed pipeline corridor investigated in this segment and seldom are used for agricultural production in the eastern portion but are used occasionally in the western portion for tame pasture and hay production.

Well to rapidly drained Orthic Sombric Brunisols along with minor amounts of Orthic Humo-Ferric Podzols, with 8-40 cm of desirable material, and developed on steeply sloping colluvial and colluvial-fluvial fan deposits occupy approximately 14% of the segment investigated and are confined to the eastern portion between Hope and Bridal Falls. Although the surface material is frequently very to exceedingly stony, it has a considerable higher organic matter content than the underlying subsoil. These soils are rarely used for agricultural production because of steep slopes and stony conditions.

Approximately 14% of the proposed pipeline corridor in this segment was not field investigated due to access restrictions. Soil classification in these areas is unknown at this time.

Land use along this segment of the proposed pipeline corridor consists of: treed land (38.8%); cultivated land (19.3%); tame pasture (13.7%); hay (12.1%); and treed pasture (2.5%). Disturbed land makes up approximately 10% The proposed pipeline corridor also crosses major rivers (0.1%) as well as golf courses and tree farms. The present land use is unknown on approximately 1% of the proposed pipeline corridor in this segment. Present land use is shown on the Environmental Alignment Sheets (Volume 6E).

A search of the BC ILRR did not identify any soil-related Crown dispositions crossed by the Hope to Burnaby Segment (BC ILMB 2013a).

Participants of the Chilliwack, Abbotsford, Coquitlam and Burnaby Community Workshops provided the following local information on soils in the area: naturally occurring asbestos is known to occur in soils in the Chilliwack and Abbotsford areas (particularly in the former Sumas Lake bed); and peaty soils are known to occur in the Coquitlam area.

Asbestos containing sediment is found in the Sumas River originating from a landslide in the 1930s on the Swift Creek tributary in Washington State. The landslide is composed of serpentinite rock which is rich in asbestos and heavy metals. The portion of the Sumas River flowing through the Abbotsford area has been contained within its channel by a diking system built in the 1920s and there has been no overbanking in any areas near the existing TMPL right-of-way. The risk of disturbing asbestos-rich soils in the Abbotsford area is extremely low since no sediment from the Sumas River has been deposited on farmland since the time of the landslide. The Sumas River was dredged in the early 1980s and sediments containing asbestos are stored on the river bank and capped to prevent any exposure. Any dredged sediments from recent dredging have been deposited in a secure landfill, eliminating risk of exposure to asbestos (McTavish pers. comm.).

Burnaby to Westridge Segment

Soil investigations were not conducted along this proposed pipeline segment due to the level of existing development.

A search of the BC ILRR did not identify any soil-related Crown dispositions crossed by the Hope to Burnaby Segment (BC ILMB 2013a).

5.2.1.3 Soil Capability for Agriculture

The current state of agricultural land use along the proposed pipeline corridor is discussed in detail in Section 5.4 of Volume 5B. In addition, an agricultural assessment was conducted for the Project (see the Agricultural Assessment Technical Report of Volume 5D). This subsection provides a brief summary of agriculture along the proposed pipeline corridor.

Types of agricultural operations found within in the vicinity of the proposed pipeline corridor include: livestock (in both Alberta and BC); poultry farms (located only in BC); vegetables (mainly in BC); grains and oilseeds (mainly in Alberta); nursery and floriculture operations (found only in BC); and fruits, berries and nuts (found mainly in BC).

The proposed pipeline corridor crosses several landscapes and climate zones with the following regional agricultural land use characteristics.

- Prairie climate in the City of Edmonton and surroundings with hot summers and cold winters, consisting of dry land agriculture.
- Towards the eastern Rocky Mountains, prevalence of pasture, grazing and beef production.
- In the North Thompson River Valley, forestry and some forest grazing.
- Near the City of Kamloops and towards the City of Merritt, arid conditions with upland forest and rangeland grazing. Typical agriculture is beef production, with irrigated forage production near water and intensive crop production in the valley bottom of the North Thompson River.
- In the Fraser Valley, a moderate climate favouring high density, irrigated field production and supporting intensive livestock operations.

Participants of the Abbotsford ESA Workshop raised concerns regarding soil disturbance issues and how the construction process would disturb crop growth. Further details on the Abbotsford ESA Workshop are provided in Volume 3A.

5.2.1.4 Soil Diseases

Clubroot Disease

Clubroot is a soil-borne disease caused by the plant pathogen *Plasmodiophora brassicae*, which affects canola, mustard and cole crops in the cabbage (*Brassicaceae*) family. It is considered a pest under the Alberta *Agricultural Pests Act* and was first detected in Alberta in a canola field near Edmonton in 2003 and is known to sporadically affect cole crops in the Lower Mainland of BC. Clubroot disease is spread through resting spores in the soil which can survive for up to 20 years. Symptoms will vary depending on the growth stage of the crop when infection occurs. Infection at the seedling stage can result in wilting, stunting and yellowing of plants. In later stages, infected plants will ripen prematurely and seeds will shrivel, reducing yield and quality of crop. A common physical feature and identifier of clubroot is gall formation on the roots of affected plants (AARD 2010).

Parkland and Yellowhead counties in Alberta and Fraser-Fort George, Thompson-Nicola, Fraser Valley and the Greater Vancouver Regional District (GVRD) in BC, which are traversed by the proposed pipeline corridor, were contacted to gather information on clubroot occurrences as well as to discuss any concerns or information the county/municipal/regional district representatives may have with regard to clubroot disease.

Table C2.1-1 in Appendix C of the Pipeline EPP (Volume 6B) summarizes known occurrences of clubroot in Alberta and BC. In Alberta, clubroot disease has been identified at 149 locations in Parkland County (Leskiw pers. comm.) and 3 locations in Yellowhead County (Pichette pers. comm.). In BC, clubroot disease has been found in cole crops in the Fraser Valley (Joshi pers. comm.). Generally, the risk of clubroot disease is higher along the eastern (Parkland County, Alberta) end of the proposed pipeline corridor, where there are many confirmed cases of clubroot, and in lower western BC (GVRD, BC).

Potato Cyst Nematode

Potato cyst nematodes are small invertebrate roundworms that attach themselves to the roots of host crops of the nightshade (*Solanaceae*) family (*i.e.*, potatoes, tomatoes and eggplant). They can inhibit the development of host plants, causing substantial growth retardation and, under severe outbreaks, damage to the roots and early senescence of the plants. The two common species of potato cyst nematodes found in Canada are golden nematode (*Globodera rostochiensis*) and pale potato cyst nematode (*Globodera pallida*). These soil-borne pests are primarily spread through the movement of cyst-infested soils. A potato cyst nematode infection does not result in obvious or unique symptoms. However, secondary symptoms such as reduced root system growth due to nutrient deficiencies and water stress, wilting, yellowing and reduced plant size are common indicators of what may be a cyst infection. If a severe potato cyst nematode infection is present in the crop, extensive plant death leading to yield loss can occur (Canadian Food Inspection Agency [CFIA] 2012).

Potato cyst nematodes are considered pests under Alberta's *Pest and Nuisance Control Regulation* and regulated by the CFIA under the *Plant Protection Act*. Currently, there is no legislation in place restricting access to potentially infected fields. However, if potato cyst nematode is confirmed at a given location, the CFIA may put the field under regulation. Potato cyst nematode regulated fields are monitored for access and equipment/vehicle sanitation. Furthermore, any equipment moving off a CFIA-regulated field needs a CFIA Movement Certificate.

Through landowner consultation, Trans Mountain has identified one cultivated field near the City of Spruce Grove, Alberta that may be potentially contaminated with potato cyst nematode (Worobec pers. comm.). The risk of spreading potato cyst nematode is low since the contamination is not yet confirmed and limited to a single location.

5.2.2 Soil Degradation

5.2.2.1 Edmonton to Hinton Segment

According to Coote and Pettapiece (1989), wind is not considered a major erosion agent along the proposed pipeline corridor between Edmonton (RK 0.0) and the Edson Pump Station (RK 247.3). Most of this area is mapped as having a negligible or low wind erosion risk. Water (spring snow melt and summer rainfall storm intensities and duration) is also considered an erosion agent. However, due to the relatively flat terrain over much of the proposed pipeline corridor along this segment, water is not considered a serious erosion agent either.

All sandy-textured soils are rated as having a high wind erosion hazard. This includes Elk Point, gleyed Gabriel, Hoadley, Peace Hills, Primula, Rochester, peaty Rochester, shallow Rochester and Sundance soils. Carvel and Winterburn soils vary in texture from sandy loam to silty clay loam and are rated as having a moderate-high wind erosion hazard. Soils rated as having a moderate-high or high wind erosion hazard occupy less than 17% of the proposed pipeline corridor from RK 0.0 to RK 247.3.

All soils occurring on less than 10% slopes are rated as having a slight water erosion hazard while those occurring on 10-15% slopes are rated as having a moderate water erosion hazard. Since the topography along the proposed pipeline corridor in this segment is seldom steeper than moderately rolling (> 15% slopes), water erosion of soil particles should not be of great concern. The steep slopes along the Rough Broken land unit are a concern and are rated as having a high water erosion hazard when the vegetation is disturbed. Some of the Angus Ridge, Cooking Lake, Carvel, Hubalta, Modeste, Malmo Primula and Winterburn soils also occur on strongly rolling topography and are rated as having a high water erosion hazard when the vegetation is disturbed. However, these areas are of minor extent.

Poorly-drained Haight, Kerensky, MacKay, Onoway, Rochester, Raven and Wildwood soils, as well as their peaty phases, are highly susceptible to soil compaction and rutting because these soils are generally wet most of the year. Fine-textured Bremay, shallow Bremay, Macola, Malmo and Maywood soils, although better drained than the Gleysolic soils, are also susceptible to soil compaction and rutting due to their silty clay loam surface texture. In addition, there are areas of gleyed soils (gleyed phase) which are also susceptible to soil compaction and rutting, especially when moist conditions prevail. The peat material of Devon soils is also susceptible to soil compaction. The compacted peat material may restrict future drainage through the organic material. Approximately 37% of the soils along the proposed pipeline corridor along this segment that were investigated are susceptible to soil compaction and rutting.

Due to the relatively flat terrain and the occurrence of many poorly-drained or imperfectly-drained soils along portions of the proposed pipeline corridor in this segment, soil compaction and rutting may be a concern, especially if construction occurs under moist conditions.

5.2.2.2 Hargreaves to Darfield Segment

Since many of the soils are sandy textured, many of the soils are rated as having a high or moderate to high wind erosion hazard when the protective vegetation is disturbed. The finer textured Allie, gleyed Allie, shallow Allie, gleyed Blackpool, Blackpool overlying gravel, Blue River, Cottonwood, gleyed Cottonwood, shallow Cottonwood, Exious, Fox, Lichen, Lucerne, shallow Lucerne, stony Lucerne, Mosquito, Rego Humic Gleysol, Struthers 3, Vermillion Lakes, Valemount and gleyed Valemount soils are rated as having a moderate wind erosion hazard. Soils rated as having a high or moderate to high wind erosion hazard occupy approximately 68% of the proposed pipeline corridor investigated in this segment.

Soils occurring on greater than 15% slopes are rated as having a high water erosion hazard. Slopes frequently exceed 15% in upland areas along the proposed pipeline corridor investigated in this segment; therefore, water erosion of soil particles may be a concern, especially in the northern portion where a greater amount of precipitation occurs. The Rough Broken land unit adjacent to deeply incised creeks or rivers are highly susceptible to soil erosion and slumping when the protective vegetation is removed.

Poorly and very poorly-drained soils as well as some of the imperfectly-drained soils are susceptible to compaction and rutting. Gleyed Allie, Blue River, peaty Blue River, gleyed Cottonwood, Ghita 1, Ghita 2, Mosquito, Rego Humic Gleysol, peaty Rego Humic Gleysol, Vermillion Lakes and peaty Vermillion Lakes soils are all susceptible to soil compaction and rutting. These soils occupy less than 7% of the proposed pipeline corridor investigated in this segment.

5.2.2.3 Black Pines to Hope Segment

Since many of the soils are sandy textured, many of the soils are rated as having a high or moderate to high wind erosion hazard when the protective vegetation is disturbed. The finer textured Chasm, shallow Chasm, Commonage, Flat Creek, saline Flat Creek, shallow Flat Creek, Frances, Gwenn, Lundbom,

Lundbom 1, Lac du Bois, McQueen, stony McQueen, Mossey, Timber, shallow Timber, stony Timber, Tunkwa, shallow Tunkwa, Tullee, shallow Tullee, Tranquille, shallow Tranquille, Trapp Lake, gleyed Trapp Lake and shallow Trapp Lake soils are rated as having a moderate wind erosion hazard. Soils rated as having a high or moderate to high wind erosion hazard occupy approximately 26% of the proposed pipeline corridor investigated in this segment.

Slopes frequently exceed 15% in upland areas along the proposed pipeline corridor in this segment; therefore, water erosion of soil particles may be a concern, especially in the southern portion where a greater amount of precipitation occurs. Water erosion protective measures may have to be initiated on slopes that exceed 15%. The Rough Broken land unit adjacent to deeply incised creeks or rivers are highly susceptible to soil erosion and slumping when the protective vegetation is removed.

Poorly and very poorly drained soils as well as some of the imperfectly drained soils are susceptible to soil compaction and rutting. Orthic Humic Gleysols, Typic Mesisols and gleyed Trapp Lake soils are identified as being highly susceptible to soil compaction and rutting. These soils occupy less than 1% of the proposed pipeline corridor investigated in this segment.

5.2.2.4 Hope to Burnaby Segment

Soils that have a sandy and/or gravelly surface texture are rated as having a high or moderate to high wind erosion hazard when the protective vegetation is disturbed. This includes Cheam, shallow Cheam, Cheam 1, bouldery Cheam, shallow Cheam 1, Harrison, Harrison 1, Isar, Laidlaw, Sumas, Sardis and Sunshine soils. These soils occupy approximately 30% of the proposed pipeline corridor investigated in this segment.

Slopes frequently exceed 15% in upland areas along the proposed corridor in this segment; therefore, water erosion of soil particles may be a concern, especially in the eastern portion where steeper slopes are common. Water erosion protective measures may have to be initiated on slopes that exceed 15%. The Rough Broken land unit adjacent to deeply incised creeks or rivers are highly susceptible to soil erosion and slumping when the protective vegetation is removed.

Poorly and very poorly drained soils as well as some of the imperfectly drained soils are highly susceptible to soil compaction and rutting. These soils occupy approximately 27% of the segment investigated. Due to the relatively flat terrain and the occurrence of many poorly drained soils on the Fraser River Lowlands where there is a high water table throughout the winter months, soil compaction and rutting will be a concern.

5.2.2.5 Burnaby to Westridge Segment

Soil investigations were not conducted along this proposed pipeline segment due to the level of existing development.

5.2.3 Bedrock and Stone Disposal

5.2.3.1 Edmonton to Hinton Segment

Stony Cooking Lake, shallow Rochester and shallow Rosevear soils are known to be stony at the surface. Bedrock within trench depth may be encountered in shallow Bremay, shallow Dekalta, shallow Hubalta and Modeste soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.2.3.2 Hargreaves to Darfield Segment

Bouldery Albreta 1, bouldery Kwikoit 1, bouldery Roserim, bouldery Struthers 1, bouldery Stukemapten, stony Lucerne, stony Roserim and stony Woodley soils are known to be stony at the surface. Bedrock within trench depth may be encountered in Fox, shallow Allie, shallow Lucerne, shallow Roserim, shallow, bouldery Stukemapten and shallow Snookwa soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.2.3.3 Black Pines to Hope Segment

Bouldery Minnie, shallow Flat Creek, stony Glossey 1, stony Minnie, stony McQueen and stony Timber soils are known to be stony at the surface. Bedrock within trench depth may be encountered in shallow Chasm, shallow Courtney, shallow Minnie, shallow Timber, shallow Tunkwa, shallow Tullee, shallow Tranquille and shallow Trapp Lake soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.2.3.4 Hope to Burnaby Segment

Cheam, Cheam 1, bouldery Cheam 1, Harrison, Harrison 1 and bouldery Kenworthy soils are known to be stony at the surface. Bedrock within trench depth may be encountered in shallow Cheam and shallow Cheam 1 soils. The Soils Technical Report of Volume 5C provides additional information on these soil units. The locations of these soil units along the proposed pipeline corridor are shown on the Environmental Alignment Sheets (Volume 6E).

5.2.3.5 Burnaby to Westridge Segment

Soil investigations were not conducted along this proposed pipeline segment due to the level of existing development.

5.2.4 Soil Contamination

This subsection describes known locations of contaminated soils in the Soil LSA, including sites identified by Trans Mountain. Project-related effects and mitigation pertaining to known contaminated sites are presented in Section 7.2.2. The potential effects and mitigation related to small spills during construction are discussed in Section 7.9.

A search of the company's historical records was conducted for the Project. To address the releases, various methods were employed to the standards of the time. There are five locations where historical spills occurred that may be crossed by the proposed pipeline corridor. Soil testing will occur prior to soil disturbance (*i.e.*, construction) to ensure soil is not contaminated. If results indicate some residual contamination, the Contamination Discovery Contingency Plan (Appendix B of the Pipeline EPP of Volume 6B) will be implemented.

The likelihood of encountering contaminated soils is considered to be higher adjacent to previously-disturbed lands (*e.g.*, existing mines and roads). Possible sources of future soil contamination are limited to spot spills and leaks during construction and maintenance activities, thereby indicating an overall low potential for soil contamination along the proposed pipeline corridor.

An inventory of potentially contaminated sites related to other land users was prepared. If evidence of contamination is noted during construction, the Contamination Discovery Contingency Plan (Appendix B of the Pipeline EPP of Volume 6B) will be implemented.

5.3 Water Quality and Quantity

This subsection presents a summary of existing information and findings related to water quality and quantity, and describe the hydrological resources within the Water Quality and Quantity LSA and Aquatics RSA. The indicators selected for this element discussed below include surface water quantity, surface water quality, groundwater quality and groundwater quantity. The rationale for the selection of indicators is provided in Section 7.2.3. Locations of watercourse crossings and groundwater-related concerns along the proposed pipeline corridor are identified on the Environmental Alignment Sheets (Volume 6E). The potential Project-related effects and mitigation pertaining to water quality and quantity are discussed in Section 7.2.3. Refer to the Groundwater Technical Report of Volume 5C for additional details on the existing conditions of groundwater quantity and quality.

This setting discusses water quality and quantity within the Water Quality and Quantity LSA and the Aquatics RSA. The Water Quality and Quantity LSA is the area generally extending 100 m upstream of the centre of the proposed pipeline corridor to a minimum of 300 m downstream of the centre of the proposed pipeline corridor, as well as within 300 m of the proposed pipeline corridor, facility or trenchless crossing entrance in potentially vulnerable aquifer areas in hydraulic connection with the Footprint and in consideration of surface water drainage patterns along the pipeline corridor. The Aquatics RSA includes all watersheds directly affected by the Project and applies to surface water. The spatial boundary of the Aquatics RSA is shown on Figures 5.3-1 and 5.3-2.

5.3.1 Surface Water Quality

Surface water quality varies naturally from site to site and from year to year. There are many natural and human influences that have the ability to affect surface water quality. Increased precipitation causes elevated surface runoff, which facilitates the transport of materials from land to water. In addition to increasing sediment and turbidity levels, elevated flows brought on by increased precipitation or spring melt events can lead to greater transport and release of potential contaminants, both naturally occurring or as a result of human activity, into the water column. Conversely, water quality may appear better during low flow periods of the year or during drier years, since dry conditions cause less surface runoff and fewer contaminants coming from the land to the watercourse.

In addition to precipitation flow volume, climate and precipitation, soil type, local geology and groundwater also influence surface water quality. However, most persistent trends can be linked to human influence. Any activity that alters water quantity or affects inputs from point sources (*e.g.*, sewage outfalls) or non-point sources (*e.g.*, agricultural runoff) has the potential to influence water quality.

Certain water quality parameters such as pH, dissolved oxygen, conductivity and turbidity were obtained for many watercourses crossed by the proposed pipeline corridor during field programs conducted during 2012 and 2013 as part of the aquatics assessments for the Project (Fisheries [Alberta] Technical Report and Fisheries [British Columbia] Technical Report of Volume 5C).

In 2012 and 2013, TEK was gathered and recorded pertaining to water quality and quantity concerns during the fisheries field program along the proposed pipeline corridor.

ALL LOCATIONS APPROXIMATE

5.3.1.1 Edmonton to Hinton Segment

The following subsections describe the planning and management of surface water, the state of surface water quality and surface water use along the Edmonton to Hinton Segment.

Planning and Management

The proposed pipeline corridor in Alberta lies within two of Alberta's Watershed Planning and Advisory Councils (WPAC[s]) – the North Saskatchewan Watershed Alliance (NSWA) and the Athabasca Watershed Council (AWC). Designated by the Government of Alberta, the main purpose of these independent, non-profit organizations is to assess the condition of each WPAC watershed and prepare plans and solutions to address watershed issues to protect and improve water quality and ecosystem function (Alberta Environment and Sustainable Resource Development [AESRD] 2013a).

An Integrated Watershed Management Plan for the North Saskatchewan River was prepared in June 2012 (NSWA 2012). The purpose of the plan is to provide recommendations and an approach to manage the North Saskatchewan River watershed, sustain water resources for the long-term and to meet the three strategic goals of Water for Life: Alberta's Strategy for Sustainability, which are:

- safe, secure drinking water;
- healthy aquatic ecosystems; and
- reliable, quality water supplies for a sustainable economy (AESRD 2013b).

To develop its Integrated Watershed Management Plan, the NSWA prepared a State of the North Saskatchewan Watershed Report in 2005. Since then, the NSWA has prepared many technical reports and public information documents concerning the assessment of water quality, water quantity (supply and instream flow needs), groundwater, cumulative effects, climate change, economics and water use. The NSWA also prepared a Discussion Paper that summarizes the planning process conducted, the issues raised in the engagement process, the legislative and policy context for watershed management in Alberta, and the results of research and technical studies (NSWA 2013).

An Integrated Watershed Management Plan for the Athabasca River watershed is currently under development by the AWC (2012). The AWC is currently working to identify environmental issues in the watershed by compiling, analyzing and interpreting scientific and technical information into a multi-phase Athabasca State of the Watershed Report. Recommended solutions to issues identified in the various phases of the report will be compiled into the Athabasca Integrated Watershed Management Plan (AWC 2012).

Parkland County has introduced an Environmental Advisory Committee (EAC), whose mandate is to assist Council in making sound decisions regarding the environment. One of the responsibilities of the EAC is to ensure water conservation and protection (Parkland County 2013a). Yellowhead County may require industrial developers to determine how the proposed Project will retain trees and environmental features such as watercourses and wetlands. Industrial developers may also be required to prove how water and sewer servicing will be safely and cost-effectively provided (Yellowhead County 2013). A policy of Yellowhead County is to work with the Province of Alberta to support a safe and secure drinking water supply for residents through ongoing record-keeping of water supply and quality from surface and groundwater sources throughout the county. Yellowhead County will also support healthy aquatic ecosystems by participating in relevant watershed planning processes that may be initiated in the future (Yellowhead County 2013).

State of Surface Water Quality

Surface water quality risk in the Aquatics RSA ranges from a rating of 0.0-1.00 (with 1 being the highest risk and 0 being the lowest risk) (AARD 2005d). Only the east half of the proposed pipeline corridor along this segment is rated, with the highest rating of 0.76-1.00 surrounding Edmonton, with the level of risk generally decreasing further west. The dominant land use surrounding the east half of the proposed pipeline corridor along this segment is agricultural. This attributes to the higher risk ratings, since the potential exists for non-point source discharges of sediment and chemicals used in pesticides and fertilizers into surrounding surface water. Potential contributing factors also include a rise in the volume of municipal wastewater effluent, runoff from domestic lawn care products and increased soil erosion.

The Alberta River Water Quality Index was developed specifically as a way to summarize physical, chemical and biological data into a simple descriptor of water quality. The index provides a simple snapshot of annual water quality conditions in major rivers of the province. The formula used to calculate the individual sub-indices is the same as that used for the Canadian Council of Ministers of the Environment (CCME) Water Quality Index. However, the method for compiling the overall Index is tailored to Alberta.

Using CCME guidelines, AESRD sampled surface water quality at specific stations and compared against CCME and other water quality guidelines to compile an index value for water quality. AESRD monitors surface water quality at many river and lake locations each year; however, only data collected as part of the province's Long-term River Network are currently used for the index. Index values are calculated annually for each site based on data collected monthly or quarterly from April to March. Index results are reported as a number between 0 and 100, where 100 represents the best quality. Index values are calculated for the four variable groups (metals, nutrients, bacteria and pesticides). These are then averaged to produce an overall River Water Quality Index (AESRD 2013c). Table 5.3-1 provides the water quality sub-index and overall index values at select locations. Sites are chosen to represent water quality conditions up and downstream of areas of substantial human activity.

TABLE 5.3-1

WATER QUALITY SUB-INDEX AND INDEX VALUES AT SELECT LOCATIONS ALONG THE EDMONTON TO HINTON SEGMENT (2009 TO 2010)

Sample Location	Sub-Index Values (0-100)				Overall Index (Average)
	Metals	Nutrients	Bacteria	Pesticides	
Athabasca River Upstream of Hinton	100	90	100	100	98
Athabasca River at Athabasca	97	89	100	96	96
North Saskatchewan River at Devon	100	100	100	96	99
North Saskatchewan River at Pakan	97	81	86	92	89

Source: Alberta Environment (AENV) 2011

AESRD and the City of Edmonton monitor and study the water quality of the North Saskatchewan River for bacteria, nutrient and heavy metal levels as well as the health of organisms living on the river bottom. Water quality close to Edmonton is monitored at two provincial long-term monitoring sites located upstream and downstream of Fort Saskatchewan (*i.e.*, at the towns of Devon and Pakan) (Table 5.3-1). Water quality conditions at the site downstream of the City of Edmonton (Pakan) reflect urban, industrial and other effects. Specifically, water quality declines in a downstream direction due to increased loading of contaminants from non-point source runoff and effluent discharges (AENV 2007).

The proposed pipeline corridor does not cross the Athabasca River; however, many tributaries, including the McLeod and Pembina rivers, enter the Athabasca River between the two stations in Table 5.3-1. A comparison of water quality between the two Athabasca stations indicate water quality in watersheds between the two stations is of a quality as to not substantially contribute to poorer water quality upstream at the Athabasca station. Input from tributaries coursing through agricultural areas is a possible cause for the slightly lower index resulting from increased nutrient loading and pesticides (AENV 2011). For example, although dated, a 1993-1994 fall-winter water quality study of the lower Pembina River observed moderately high levels of nutrients and organic material, likely attributed to natural and anthropogenic sources (Noton 1996). Furthermore, the upper and middle reaches of the Athabasca River receive continuous discharges from several pulp mills and wastewater treatment plants in Jasper, Hinton, Whitecourt and Athabasca, point sources contributing to nutrient enrichment and declined oxygen levels during late winter (AENV 2007). Nevertheless, an index value of 96-100 indicates excellent water quality, where guidelines are almost always met.

A basin-wide survey of the Athabasca River Basin reported no widespread contamination of sediments by contaminants including dioxins and furans, polychlorinated biphenyls (PCBs), resin acids and polycyclic aromatic hydrocarbons (PAHs). Locally higher levels of sediment contamination were recorded downstream of the Town of Hinton, attributed to pulp mill effluent discharges (AENV 2007). The McLeod River has a substantial influence on the Athabasca River, with water quality of the McLeod River rated as fair. The McLeod River discharges the largest volume of water to the middle Athabasca River and contributes the largest suspended sediment and associated nutrient loads due to forestry activities, mining, agriculture, forest fires, peatlands, wetlands and other natural sources.

Water quality at the Athabasca River (at Athabasca) and North Saskatchewan River (at Devon) improved from good to excellent from the 2008 to 2009 reporting period. The long-term station at Pakan shows water quality steadily improving from an index low of 74 (fair [*i.e.*, guidelines sometimes exceeded by moderate amounts; quality occasionally departs from desirable levels]) in 2003 to 2004 and 2004 to 2005 monitoring periods, to 89 (good [*i.e.*, guidelines occasionally exceeded, but usually by small amounts; threat to quality is minimal]) in the 2008 to 2009 and 2009 to 2010 monitoring periods. As in the case of several other provincial rivers, this may have been partly influenced by a decline in precipitation. This is evidenced by stream flows that were well below the historical average. Lower flows are frequently indicative of fewer non-point source inputs to the river, which may result in fewer guideline exceedances and higher Index ratings (AENV 2011).

The Village of Wabamun is sensitive about water issues due to the CN freight train derailment in 2005. Refer to Section 7.7 of the Socio-Economic Technical Report (Volume 5D) for additional details on this incident. Since the early 1980s, AENV has sampled Wabamun Lake monthly in open water periods (May to October) and at least once during the winter. Some aspects of the lake's water quality have changed over time. Total dissolved solids and most major ion concentrations in Wabamun Lake have increased over the last 20 years. There has been a further increase in total dissolved solids and sulphate in Wabamun Lake beginning in 1999 when the Wabamun Lake Water Treatment Plant started pumping large volumes of treated water into the lake. However, plankton communities showed no major change from the early 1990s to 2001 and Wabamun Lake remains nutrient-rich (AENV 2002).

The Edmonton Waterworks System generally reports no drinking water safety concerns. In January 2013, the total chlorine residual was found to be outside of the acceptable range. The Government of Alberta worked with the provider to ensure that the public was not at risk from the drinking water (AESRD 2013d).

During the fisheries field program, TEK participants reported that water quality has been declining steadily over the past 30 years at watercourses along the proposed Edmonton to Hinton Segment, while at watercourses nearer to the Rocky Mountains, the water is still clean. This steady decline is considered by TEK participants to be due to the cumulative effects of pollution and industrial development in the region. Additional TEK related to surface water quality along the proposed Edmonton to Hinton Segment is provided in the Fisheries (Alberta) Technical Report of Volume 5C.

During the 2012 and 2013 fisheries field surveys, sampling was conducted for certain water quality parameters (*e.g.*, temperature, dissolved oxygen, pH, conductivity) at watercourse crossings identified along the proposed pipeline corridor and are documented in the Fish-Bearing Atlas for Alberta (see Appendix C of the Fisheries [Alberta] Technical Report in Volume 5C).

Surface Water Use

Drinking water sources for communities along the proposed pipeline corridor along the Edmonton to Hinton Segment are provided in Table 5.3-2.

TABLE 5.3-2

MUNICIPAL DRINKING WATER SOURCES FOR COMMUNITIES LOCATED ALONG THE PROPOSED EDMONTON TO HINTON SEGMENT

Community	Source(s)	Location Relative to Proposed Pipeline Crossing
City of Edmonton	Two water treatment plants along the North Saskatchewan River supply water to the city (EPCOR Water Services Inc. 2010).	E.L. Smith Water Treatment Plant approximately 6 km upstream. Rossdale Water Treatment Plant approximately 10 km downstream.
City of Spruce Grove	Water is supplied to the City of Spruce Grove by a pipeline from the City of Edmonton.	N/A
Town of Stony Plain	Water is supplied to the Town of Stony Plain by a pipeline from the City of Edmonton. A 3,000,000 gallon (11,360 m^3) reservoir is situated in the town and water is pumped from this into the distribution system (Alberta Community Profiles 2013).	N/A
Village of Wabamun	Currently, water is from groundwater wells located approximately 1 km south of the proposed pipeline corridor. However, a water supply pipeline is under construction as of October 2013 from the Town of Stony Plain (During pers. comm.).	N/A
Hamlet of Entwistle	Entwistle primarily utilizes the sandstone aquifer of the Paskapoo formation for its water needs (Parkland County 2012).	N/A
Hamlet of Evansburg	Evansburg receives water supply from three wells located 4 km south of the water treatment plant at S1/2 13-53-8 W5M (Yellowhead County 2003).	N/A
Hamlet of Wildwood	Groundwater.	N/A
Town of Edson	Edson's potable water source is the groundwater resources in aquifers which lie beneath the town. As the town has grown, the aquifers have been slowly declining and have been exploring methods to augment the town's water supply either by artificially recharging the aquifers or building a water treatment plant that will draw from the McLeod River (Yellowhead County 2007).	N/A
Town of Hinton	Athabasca River (information from Hinton Community Workshop).	Approximately 2 km north.

To account for the variable downstream extent of the Water Quality and Quantity LSA, surface water licences were identified within a conservative downstream length of 5 km from pipeline crossings. Due to the large number of surface water licences in Alberta, providing details for every licence identified such as location, status and purpose, was considered impractical. Alternatively, for the purposes of this ESA, a descriptive approach of identifying surface water licences based on approximate observations of the available data is provided.

Based on examination of the AESRD surface water licence online database, there are several hundred approvals, licences, registrations, authorizations, permits and/or certificates issued under the *Water Act* and Alberta *Environmental Protection and Enhancement Act* within 5 km downstream of watercourses crossed by the proposed pipeline corridor along this segment (Government of Alberta 2013a). Many licences were for past temporary use and, consequently, are either expired or no longer active (*e.g.*, for hydrostatic testing). In the Edmonton area, presently active licences within 5 km were issued for public activities (*e.g.*, watermains), construction activities and industry operations. West of Edmonton, licences are issued for the aforementioned uses as well as for agricultural purposes (*e.g.*, irrigation); however, the frequency of water licences generally decreases heading further west of Edmonton. Surface water points of diversion within 5 km of pipeline crossings that are currently in use could not specifically be identified in Alberta for this ESA due to a lack of usable data and/or specific details.

5.3.1.2 Hargreaves to Darfield Segment

The following subsections describe the planning and management of surface water, the state of surface water quality and surface water use along the Hargreaves to Darfield Segment.

Planning and Management

The proposed pipeline corridor traverses the upper Fraser River Basin from RK 489.6 to RK 527.9 and RK 547.7 to RK 769. The Fraser Basin Council (FBC) is a collaboration of four orders of government (federal, provincial, local and Aboriginal communities), along with those from the private sector and the general public that are brought together to advance sustainability in the Fraser Basin. The FBC is available to assist public, private and non-profit organizations with their sustainability challenges. The FBC is facilitating several regional initiatives to improve the health of watersheds including helping advance a Collaborative Watershed Governance Initiative (CWGI) for the sustainable management of BC's watersheds (FBC 2013).

The proposed pipeline corridor traverses the Columbia River Basin from RK 527.9 to RK 547.7. The Columbia Basin Trust (CBT) was created in 1995 to support efforts by the people of the basin to create social, economic and environmental well-being in the Canadian portion of the Columbia River Basin. The CBT works with the people that live in the basin to develop and deliver programs and initiatives that respond to their needs and supports communities. The CBT has created an Environmental Strategic Plan that was developed in response to the concerns of the people of the basin. Objectives and goals in the Environmental Strategic Plan include providing resources to projects, programs and collaborative efforts, supporting positive environmental action within the basin and promoting an understanding of organizational activities which reduce environmental effects in the basin (CBT 2009).

The Hargreaves to Darfield Segment is located within the Thompson-Nicola Regional District (TNRD) which has in place a Regional Growth Strategy where one of its mandates is to protect and enhance the quality and quantity of the water of the region's lakes, rivers, streams and groundwater sources (TNRD 2013). One other principle identified in this strategy is to develop policies and legislation to identify, conserve and protect the natural environment, including mapping of sensitive ecosystems and designating development permit areas.

State of Surface Water Quality

In general, the Fraser River tends to be turbid at its headwaters due to glacial flour and insoluble silts and clays from bedrock dissolution. Water quality reports are available for the Fraser River at Red Pass (located below Moose Lake in the headwaters of the Fraser River) which is the first of five long-term monitoring stations on the Fraser River. These reports represent ambient conditions that can be compared with water quality at downstream sites. Water quality concerns include increases in total metals which appear to be a result of increasing turbidity due to natural erosion processes, as well as an increase in conductivity and hardness. However, levels have remained stable since 1992 and an increase in nickel concentrations has been reduced in recent years, remaining well below guideline levels for aquatic life. Overall, the water quality of the Fraser River at the Red Pass site is ranked as good to excellent (BC Ministry of Environment [MOE] 2007a).

BC developed a Water Quality Index in 1995 that uses CCME guidelines. Variables that were measured at selected sites across BC included physical characteristics, nutrients, metals, major ions and other compounds such as pesticides. From 2002 to 2004, the Fraser River at Red Pass sampling site was ranked as excellent – the highest ranking of the 31 sites (BC MOE 2007b). From 1985 to 2004, this site has showed improved water quality due to the removal of lead from gasoline; however, it has also showed increased levels of nickel and manganese due to natural erosion and surface runoff from highways, respectively (BC MOE 2007b).

The BC MOE's Thompson Region developed a watershed prioritization matrix to identify watersheds within the region at highest risk of anthropogenic effects on water quality and its designated users. Watershed attributes with potential to affect water quality conditions that were considered in the risk rankings included a number of natural watershed characteristics (*e.g.*, watershed slope and drainage density) and human land uses (*e.g.*, road density, forest harvesting and agriculture). Of the watersheds tested, the headwaters of the North Thompson River to Clearwater and from Clearwater to Barriere were the watershed units relevant to the proposed pipeline segment. Both of these watershed units were ranked within the top ten watershed units at high risk of anthropogenic effects on water quality and water users due to urbanization, agriculture, mining, and road and stream crossing densities compared to other watershed units within the Thompson Region (BC MOE 2011a).

During the fisheries field program, TEK participants reported that water quality is steadily declining due to increased agriculture and logging activities. Participants felt that water temperatures are rising, in general, due to climate change. Additional TEK related to surface water quality along the proposed Hargreaves to Darfield Segment is provided in the Fisheries (British Columbia) Technical Report of Volume 5C.

During the 2012 and 2013 fisheries field surveys, sampling was conducted for certain water quality parameters (*e.g.*, temperature, dissolved oxygen, pH, conductivity) at watercourse crossings identified along the proposed pipeline corridor and are documented in the Fish-Bearing Atlas for BC (see Appendix B of the Fisheries [British Columbia] Technical Report in Volume 5C).

Surface Water Use

The BC Ministry of Health is responsible for overseeing the implementation of the *Drinking Water Protection Act* and *Drinking Water Protection Regulation*. The Village of Valemount gets its drinking water from Swift Creek and is considering groundwater wells as a potential future supply option. During 2002/2003, Swift Creek drinking water quality was good overall with water soluble contaminants present at concentrations well below drinking water guidelines (BC MOE 2004).

The proposed pipeline corridor does not intersect any community watersheds and there are no community watersheds within 2 km downstream of any watercourse crossings. The Valemount Community Watershed is located approximately 2 km upstream from the proposed crossing of Swift Creek at RK 522.5, while the Avola Community Watershed is located approximately 500 m upstream of the proposed crossing of Avola Creek at RK 656.1 (BC MOE 2009a).

Table 5.3-3 identifies municipal drinking water sources for communities along the Hargreaves to Darfield Segment.

TABLE 5.3-3

MUNICIPAL DRINKING WATER SOURCES FOR COMMUNITIES LOCATED ALONG THE PROPOSED HARGREAVES TO DARFIELD SEGMENT

Community	Source(s)	Location Relative to Proposed Pipeline Crossing
Village of Valemount	Swift Creek (information from Valemount Community Workshop).	Approximately 2 km upstream of the proposed watercourse crossing.
Community of Blue River	Groundwater (information from Blue River Open House).	N/A (refer to Section 5.3.3.2 for additional information).
Community of Avola	Avola Creek.	Approximately 630 m upstream of the proposed watercourse crossing.
Community of Vavenby	North Thompson River.	Approximately 680 m south of the proposed pipeline corridor.
District of Clearwater	Both groundwater and surface water (Hascheak Creek).	Hascheak Creek source located approximately 1 km upstream from the North Thompson River on opposite side of proposed pipeline corridor.

There are approximately 143 registered surface water points of diversion identified within 5 km downstream of proposed pipeline crossings (BC Ministry of Forests, Lands and Natural Resource Operations [MFLNRO] 2010). The surface water licences are primarily for domestic and irrigation purposes, although other purposes include stockwatering, land improvement, conservation, watering, water works, fire protection, processing and work camps. A list of the water licences registered with BC MFLNRO within 5 km downstream of the watercourses crossed by the proposed pipeline corridor is provided in Appendix 5.1 (located at the end of Section 5.0).

5.3.1.3 Black Pines to Hope Segment

The following subsections describe the planning and management of surface water, the state of surface water quality and surface water use along the Black Pines to Hope Segment.

Planning and Management

The Black Pines to Hope Segment lies entirely within the Fraser River Basin. As mentioned above, the FBC is available to assist public, private and non-profit organizations with their sustainability challenges. The FBC is facilitating several regional initiatives to improve the health of watersheds including helping advance a CWGI for the sustainable management of BC's watersheds (FBC 2013). Within the Fraser River Basin, the proposed pipeline corridor is located within the Thompson Region and Fraser Valley. In the Thompson Region, the FBC supports projects to advance the social, economic and environmental health of the region.

State of Surface Water Quality

Water quality was monitored at the North Thompson River at North Kamloops by BC MOE from 1985 to 1995 (BC Ministry of Environment, Lands and Parks [MELP] 1997). The Clearwater Sewage Treatment Plant discharges to the ground near the North Thompson River. There are no known sources of metals and no active mines in the North Thompson watershed. However, agriculture, urbanization and forestry have impacted the watershed. Levels of aluminum, copper, iron and zinc exceeding guidelines for aquatic life or drinking water were observed in winter and fall, in association with low levels of non-filterable residue. Levels appeared to be naturally high in the North Thompson River, since higher values during low flows have occasionally occurred since monitoring began in 1987, and since there were no considerable industrial discharges into the river. Variables exceeding guidelines at times during spring freshet were aluminum, chromium, copper, iron, manganese and titanium. Overall, guidelines were consistently met for most of the sampled variables and no considerable environmental trends were found (BC MELP 1997).

The North Thompson River from Barriere to Kamloops was within the top three watershed units within the Thompson Region that are at a high risk of anthropogenic effects on water quality and its users due to high road density, stream crossing density, urban and agriculture scores (BC MOE 2011a). The Thompson and Nicola rivers ranked within the top ten watershed units at high risk of anthropogenic effects on water quality (BC MOE 2011a).

Water quality reports are available for the Fraser River at Hope, which is the monitoring station furthest downstream from the proposed pipeline corridor along this segment. Levels of most metals fluctuated with turbidity levels, which in turn corresponded to increased flows. High metal concentrations at those times that exceeded guidelines or site-specific water quality objectives would not be biologically available and, therefore, were of little concern. Other water quality values seemed to fluctuate through the year according to the specific conductivity of the water, but were below guideline values and had no other trends (BC MOE 2007c). The Fraser River at Hope Station showed good water quality from 2002 to 2004 according to the BC Water Quality Index (BC MOE 2007b). From 1979 to 2004, this station has also shown improved water quality due to improved waste abatement at pulp mills (BC MOE 2007b).

TEK related to surface water along the proposed Black Pines to Hope Segment is provided in the Fisheries (British Columbia) Technical Report of Volume 5C.

During the 2012 and 2013 fisheries field surveys, sampling was conducted for certain water quality parameters (*e.g.*, temperature, dissolved oxygen, pH, conductivity) at watercourse crossings identified along the proposed pipeline corridor and are documented in the Fish-Bearing Atlas for BC (see Appendix B of the Fisheries [British Columbia] Technical Report in Volume 5C).

Surface Water Use

The South Thompson River provides the main source of drinking water for the City of Kamloops. The intake is located approximately 8.5 km upstream from the proposed crossing of the Thompson River. The main source of drinking water for the City of Merritt and District of Hope is groundwater (refer to Section 5.3.3.3 for additional information).

The proposed pipeline corridor intersects three community watersheds. The proposed pipeline corridor crosses the Kwinshatin Community Watershed from RK 939.4 to RK 942.7 and the Skuagam Community Watershed from RK 942.7 to RK 943.8, both of which serve the Coldwater 1 Indian Reserve. The intake locations of the Kwinshatin and Skuagam community watersheds are located approximately 1.1 km and 800 m northwest of the proposed pipeline corridor at Kwinshatin and Skuagam creeks, respectively. Both watercourses are crossed by the proposed pipeline corridor. The proposed pipeline corridor east of Hope intersects the Kopp Creek Community Watershed from RK 1039.2 to RK 1039.8. The intake location of the Kopp Community Watershed is located approximately 400 m northwest of the proposed pipeline corridor at Kopp Creek, which is not crossed by the proposed pipeline corridor. The proposed pipeline corridor does not intersect any other community watersheds and there are no community watersheds within 2 km downstream of any watercourse crossings (BC MOE 2009a).

There are approximately 386 registered surface water points of diversion identified within 5 km downstream of proposed pipeline crossings (BC MFLNRO 2010). The surface water licences are primarily for domestic and irrigation purposes, although other purposes include stockwatering, waterworks, storage and conservation. A list of the water licences registered with BC MFLNRO within 5 km downstream of the watercourses crossed by the proposed pipeline corridor is provided in Appendix 5.1.

5.3.1.4 Hope to Burnaby Segment

The following subsections describe the planning and management of surface water, the state of surface water quality and surface water use along the Hope to Burnaby Segment.

Planning and Management

The Hope to Burnaby Segment is located within the Fraser River Basin. The lower Fraser River courses through the Fraser Valley Regional District (FVRD) and Metro Vancouver, and is central to supporting agriculture, recreation, tourism, forestry, fishing, transportation and natural ecosystems. The FBC is bringing together all orders of government, along with private and non-profit sector leaders, each with an interest in the Fraser River or a responsibility for some aspect of its management, to form the Lower Fraser Collaborative Initiative which will help plan a sustainable future for the lower Fraser River (FBC 2013).

The key objectives of Metro Vancouver's drinking water treatment facilities are: protecting the source (watersheds); treating water at the source and disinfecting at further points in the distribution system; cleaning and maintaining the distribution system; and monitoring water quality at all stages. Population growth will place demands not only on water supply, but also on water infrastructure if not carefully planned. Metro Vancouver developed the Drinking Water Management Plan to ensure the region's water needs are met sustainably. The goals of the Drinking Water Management Plan include providing clean, safe drinking water, ensuring the sustainable use of water resources and ensuring a sufficient supply of water (Metro Vancouver 2011a). Metro Vancouver is conducting ongoing projects on source watersheds and water distribution systems to maintain the quality of the region's drinking water as well as meet the needs of an expected population increase of 800,000 people leading up to 2025. The Seymour and Capilano watersheds supply up to 70% of the Lower Mainland's drinking water. Construction of new water supply and treatment facilities for these water sources is underway in the Lower Seymour Conservation Reserve and at Capilano River Regional Park (Metro Vancouver 2013a).

State of Surface Water Quality

Water quality data from 1979 to 1982 from the Sumas River, a tributary to the Chilliwack/Vedder River, showed that the Sumas River had good water quality except for phosphorus, fecal coliforms and asbestos (BC MOE 1985). Although phosphorus values in its lower reaches were typical of low productivity streams, higher phosphorus values and likely higher productivity existed in its upper reaches. In addition, fecal coliform values were generally high throughout the Sumas River, exceeding working water quality criteria for primary contact recreation. Naturally occurring asbestos values in the river were higher than found in most other water in North America. These high levels have been associated with high metal-levels, as well as toxicity problems to plants in flooded areas where sediments had been deposited.

Metro Vancouver's drinking water comes from reservoirs in three watersheds, namely Capilano, Seymour and Coquitlam. Metro Vancouver is committed to delivering and maintaining the best drinking water possible and protecting these three watersheds is crucial to ensuring high quality drinking water. Some of Metro Vancouver's water quality concerns include turbidity due to heavy rainfall, parasites from animals, bacteria growth due to chlorine depletes, acidity in the water causing corrosion of pipes and chlorination disinfection by-products.

Metro Vancouver's closed watershed policy provides a barrier against water contamination from human sources (Metro Vancouver 2013b). To ensure the safety of the water, Metro Vancouver conducts daily tests and takes precautions in anticipation of events that can cause high turbidity levels (Metro Vancouver 2013a). In addition, to ensure drinking water meets provincial legislation and federal guidelines, Metro Vancouver has developed a Drinking Water Treatment Program that includes primary and secondary disinfection. In 2012, the turbidity levels of the delivered water easily met the requirements of the *Guidelines for Canadian Drinking Water Quality* (Metro Vancouver 2012a). Bacteriological water quality was good in the member municipalities. Of approximately 21,000 municipal samples collected for testing in 2012, 99.9% were free of coliforms, a figure which was similar to 2011 (99.9%). In 2012, no *E.coli* was detected (Metro Vancouver 2012a).

TEK related to surface water quality along the Hope to Burnaby Segment is provided in the Fisheries (British Columbia) Technical Report of Volume 5C.

During the 2012 and 2013 fisheries field surveys, sampling was conducted for certain water quality parameters (*e.g.*, temperature, dissolved oxygen, pH, conductivity) at watercourse crossings identified along the proposed pipeline corridor and are documented in the Fish-Bearing Atlas for BC (see Appendix B of the Fisheries [British Columbia] Technical Report in Volume 5C).

Integrated Stormwater Management

In recognition of the increased pressures on local watersheds from existing land uses and expanding development, many municipalities in Metro Vancouver have prepared Integrated Stormwater Management Plans (ISMPs). The purpose of ISMPs is to examine the linkages between drainage servicing, land use planning and environmental protection in order to support the growth of a community in a way that maintains or ideally enhances the overall health of a watershed. There are many ISMPs in various stages of development; however, only three ISMPs have been identified that are crossed by the proposed pipeline corridor: Clayburn Creek in the City of Abbotsford; and Como and Nelson creeks in the City of Coquitlam.

Clayburn Creek (crossed by the proposed pipeline corridor at RK 1090.5 and RK 1091.5) is a relatively healthy watershed. However, sedimentation within the middle and upper reaches of Clayburn Creek is a major water quality concern, resulting predominantly from new development. Sampling conducted at Stony Creek and Poignant Creek (tributaries of Clayburn Creek) from 1997-2001 and in 2009 at Stoney Creek found elevated levels of fecal coliform likely attributed to hobby farms, failing septic fields in the Straiton community and at nearby cow pastures. Metal levels in sediment sampled from near the lowland-upland transition of the watershed were generally lower than at upper watershed sites; however, arsenic levels were slightly above BC MOE *Interim Sediment Quality Guidelines* (ISQGs) in Stoney Creek (near Stoney Creek Park) and nickel levels were above ISQGs in the lower part of Poignant Creek and at the Clayburn Creek lowland sampling site. Elevated arsenic levels are likely natural while the nickel levels, particularly at the lowland sampling site on Clayburn Creek, may represent contamination from human sources (Kerr Wood Leidal Associates Ltd. [Kerr Wood Leidal] 2012).

Benthic invertebrates (streambed insects) are useful indicators of stream condition and can be monitored over time to track changes instream or watershed health. As described in the Clayburn Creek ISMP, eight different sites in the watershed were sampled for invertebrates. Overall, the Clayburn Watershed had a health rating of fair (Kerr Wood Leidal 2012).

Como Creek is crossed by the proposed pipeline corridor at RK 1141.3. The main purpose of the Como Creek ISMP is to address drainage problems, particularly the chronic flooding in the lower reaches, which results in periodic property damage and road closures, as well as rapid watercourse erosion and instability. In addition, high flows and flooding tends to exacerbate existing influences on water quality resulting from pollutant runoff associated with high density development and waste discharge from industrial/commercial land uses. No specific sampling or monitoring information that may otherwise provide an indication of the state of water quality in the watershed is provided in the Como Creek ISMP (CH2M Hill Inc. 2002). Much has evolved since this ISMP was developed and updates to the plan are currently underway (City of Coquitlam 2013).

The watershed of Nelson Creek is crossed by the proposed pipeline corridor; however, Nelson Creek is not crossed. The watershed of Nelson Creek contains a high level of urban development with land uses ranging from residential in the upper reaches to commercial in the lower reaches. The health of the watershed is generally ranked poor, with water quality impacts resulting from elevated fecal coliforms, nutrients and some metals, as well as from total suspended solids (TSS) resulting from increased stream channel erosion. A water quality sampling program was conducted for the ISMP to assess baseline conditions. TSS levels and nitrogen concentrations were below provincial guidelines in all samples, while individual values for *E. coli* exceeded guidelines in all samples. Phosphorous concentrations generally decreased between upstream and downstream sampling sites, suggesting high concentrations in the upper watershed are diluted with other sources of water downstream and were higher in wet weather. Most metal parameters met BC water quality guidelines, with the exception of cadmium, copper and zinc (CH2M Hill Inc. 2010).

The City of Burnaby and AECOM are collaborating to develop an ISMP for the watershed of Eagle Creek in order to better manage land development and support environmental protection, preservation and enhancement of Eagle Creek and its tributaries. During an external stakeholder workshop for the Eagle Creek ISMP, recent studies conducted to provide an indication of the current state of water quality and quantity were summarized. Some key observations were the presence of low base flows in the late summer period, presence of iron oxide (likely naturally occurring) and downstream sedimentation, including at the Burnaby Lake inflow. The Eagle Creek ISMP will aim to address issues such as minimizing erosion and resulting problems with sedimentation in the lake, habitat enhancements, improving water quality in the stream and reducing pollution (Hill, Phang pers. comm.). The Eagle Creek ISMP is expected to be released in 2014.

Surface Water Use

The main sources of drinking water for municipalities in the Lower Mainland, including the Township of Langley and cities of Abbotsford, Surrey, Coquitlam and Burnaby, is provided by the Capilano, Seymour and Coquitlam mountain reservoirs operated by Metro Vancouver. Water is conveyed from these reservoirs by regional water mains to member municipalities for distribution to homes, businesses and industry. The Township of Langley also receives some drinking water from municipal wells. The City of Chilliwack receives most of its drinking water from municipal wells as well, specifically the Sardis Aquifer (refer to Section 5.3.3.4 for additional information).

The proposed pipeline corridor does not intersect any community watersheds along this segment and there are no community watersheds within 2 km downstream of any watercourse crossings. The Nevin Community Watershed is located approximately 1.3 km upstream from the proposed crossing of Nevin Creek at RK 1083.4, while the Dunville Community Watershed is located approximately 1.2 km upstream of the proposed crossing of Dunville Creek at RK 1083.9 (BC MOE 2009a).

There are approximately 220 registered surface water points of diversion identified within 5 km downstream of proposed pipeline crossings (BC MFLNRO 2010). The surface water licences are primarily for domestic and irrigation purposes, although other purposes include stockwatering, conservation, land improvement and sewage disposal. A list of the water licences registered with BC MFLNRO within 5 km downstream of the watercourses crossed by the proposed pipeline corridor is provided in Appendix 5.1.

5.3.1.5 Burnaby to Westridge Segment

The following subsections describe the planning and management of surface water, the state of surface water quality and surface water use along the Burnaby to Westridge Segment.

Planning and Management

The Burnaby to Westridge Segment is located within the Greater Vancouver Sea to Sky Region within the Fraser River Basin. Refer to Section 5.3.4.2 for additional information.

State of Surface Water Quality

Refer to Section 5.3.4.2 for information on the state of surface water quality in Metro Vancouver.

Surface Water Use

The City of Burnaby obtains most of its drinking water from the Capilano and Seymour reservoirs, which are operated by Metro Vancouver. The proposed pipeline corridor does not intersect any community watersheds and there are no community watersheds within 2 km downstream of any watercourse crossings (BC MOE 2009a). No registered surface water points of diversion were identified within 5 km downstream of proposed pipeline crossings (BC MFLNRO 2010).

5.3.2 Surface Water Quantity

Drainage basins, watersheds and watercourses crossed by the proposed pipeline corridor were identified and characterized through a combination of desktop analysis and field programs conducted during 2012 and 2013 as part of the aquatics assessments for the Project (Fisheries [Alberta] Technical Report and Fisheries [British Columbia] Technical Report of Volume 5C).

Surface water quantity also varies naturally from site to site and from year to year depending on, among other factors, precipitation levels and patterns, temperature and land use. To understand the range of flows at major watercourse crossings, historical data was obtained from Environment Canada hydrometric monitoring stations, which provide a long-term record of stream flow information of watercourses at specific locations. Additional streamflow data for small and large watercourses crossed by the proposed pipeline corridor, including seasonal and peak flow estimates and average monthly runoff depth, are provided in the Route Physiography and Hydrology Report prepared by BGC Engineering Inc. (Volume 4A).

5.3.2.1 Edmonton to Hinton Segment

The proposed pipeline corridor along the Edmonton to Hinton Segment crosses the Lower, Middle and Upper North Saskatchewan River watersheds and the Sturgeon River watershed, comprising the area from the City of Edmonton to the Hamlet of Evansburg, and form part of the North Saskatchewan River basin. The proposed pipeline corridor then crosses the Pembina River, Upper and Lower McLeod River and the Athabasca River watersheds to the west from the Hamlet of Evansburg to the interprovincial border near the Town of Hinton, which form part of the Athabasca River basin (AESRD 2013e). There are approximately 202 potential watercourse crossings identified along the proposed pipeline corridor along this segment. Larger watercourses crossed by the proposed pipeline corridor include the North Saskatchewan River (RK 33.5), Pembina River (RK 135.0) and McLeod River (RK 223.9), the latter two of which are tributaries of the Athabasca River. A summary of watercourse crossings in the North Saskatchewan River basin and Athabasca River basin along the proposed pipeline corridor for the Edmonton to Hinton Segment is provided in Section 5.7 Fish and Fish Habitat.

The North Saskatchewan River originates in Banff National Park of Alberta and flows east 1,287 km to join the South Saskatchewan River, forming the Saskatchewan River, which eventually drains into Hudson Bay via the Nelson River. Both the Pembina and McLeod rivers originate in the foothills of the Rocky Mountains of Alberta east of Jasper National Park, flowing for several hundred kilometres before entering the Athabasca River in central Alberta, which ultimately discharges into the Arctic Ocean via the Mackenzie River.

The proposed pipeline corridor crosses an Environmentally Significant Area (690) of national importance for riparian areas at SW 3 and NW 3-52-25 W4M and NE 4-52-25 W4M (RK 32.5 to RK 34.9). This Environmentally Significant Area extends the length of the North Saskatchewan River to the Saskatchewan border (Alberta Tourism, Parks and Recreation [ATPR] 2009). ATPR defines Environmentally Significant Areas as being important to the long-term maintenance of biological diversity, soil, water or other natural processes, at multiple spatial scales and/or areas that contain rare or unique elements or that include elements that may require special management consideration due to their conservation needs. However, ATPR also states that Environmentally Significant Areas do not represent government policy and do not necessarily require legal protection. They are intended to be an information tool to help inform land use planning and policy at local, regional and provincial scales.

No designated or nominated Canadian Heritage Rivers are crossed by the proposed pipeline corridor along this segment (Canadian Heritage Rivers System 2011a). The proposed pipeline corridor does not cross any of the 13 designated irrigation districts in Alberta (AARD 2011).

The North Saskatchewan River Basin has 20-30% of its natural flow that may be diverted under terms of licenced allocation, while only 2-5% of natural flow may be diverted from the Athabasca River Basin (AENV 2010). Flow averages from 2003 to 2012 were recorded at the Pembina River near the Hamlet of Entwistle and the North Saskatchewan River in the City of Edmonton. Flow averages for the Pembina River are documented as being Normal in all months, while the North Saskatchewan River is Below Normal from May to September and Above Normal from October to April (AESRD 2012a).

Hydrostatic test water for the Edmonton to Hinton Segment is expected to be withdrawn from the North Saskatchewan River, Pembina River and McLeod River. An estimated 81,000 m^3 of water will be needed to conduct hydrostatic testing of the proposed pipeline along this segment. Water used for hydrostatic testing will be released within the same drainage basin from where it was withdrawn.

<u>Historical Streamflow</u>

The Water Survey of Canada maintains a hydrometric station on the North Saskatchewan River at Edmonton, Alberta (Station No. 05DF001) (Environment Canada 2013b). This station is approximately 20 km downstream of the proposed crossing at RK 33.5. Discharge at this station has been recorded every year since 1911. The annual high flow event typically occurs from May to July and flows gradually decline through late summer and fall. Figure 5.3-3 shows that mean monthly flows are lowest in February at 68.7 m^3/s and mean flows are highest during the late spring freshet with a peak in July at 483 m^3/s (Environment Canada 2013b). Data for this watercourse are presented in Figure 5.3-3 and Table 5.3-4 and includes maximum, minimum and mean monthly discharges. Since this station records flow information downstream of the proposed crossing, discharge at the time of construction may be slightly less than the recorded mean discharge resulting from small tributaries (*e.g.*, Whitemud Creek) located between the station and the proposed watercourse crossing.

Figure 5.3-3 Historical Mean Monthly Streamflow (m^3/s) Summary for the North Saskatchewan River at Edmonton, Alberta (Station 05DF001)

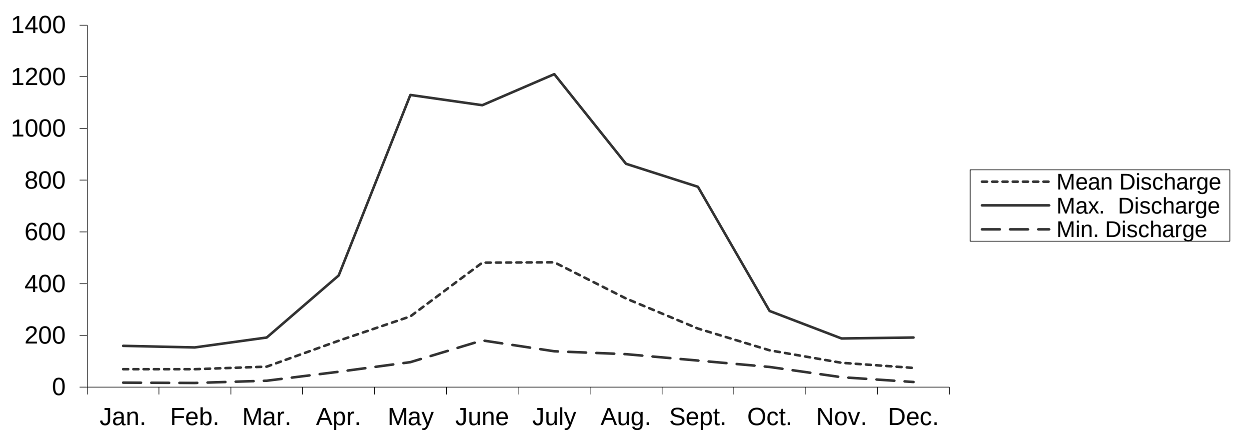

TABLE 5.3-4

HISTORICAL MEAN MONTHLY STREAMFLOW (m^3/s) SUMMARY FOR THE NORTH SASKATCHEWAN RIVER AT EDMONTON, ALBERTA (STATION 05DF001)

Discharge	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.
Mean Discharge	69.4	68.7	79.0	179.0	273.0	481.0	483.0	342.0	226.0	142.0	93.6	73.9
Max. Discharge	160.0	153.0	192.0	432.0	1,130.0	1,090.0	1,210.0	864.0	774.0	294.0	188.0	192.0

Years of Streamflow Record:	1911 to 2010											
Maximum Daily Discharge:	4,640 m^3/s on June 29, 1915											
Minimum Daily Discharge:	6.23 m^3/s on January 1, 1940											
Effective Drainage Area:	27,100 km^2											

Source: Environment Canada 2013b

The Water Survey of Canada maintains a hydrometric station on the Pembina River near Entwistle, Alberta (Station No. 07BB002) (Environment Canada 2013c). This station is approximately 2 km downstream of the proposed crossing at RK 135.0. Discharge at this station has been recorded for approximately 66 years between 1914 and 2010. The annual high flow event typically occurs from May to July and flows gradually decline through late summer and fall. Figure 5.3-4 shows that mean monthly flows are lowest in February at 2.31 m³/s and mean flows are highest during the spring freshet with a peak in May at 48.9 m³/s (Environment Canada 2013c). Data for this watercourse are presented in Figure 5.3-4 and Table 5.3-5 and includes maximum, minimum and mean monthly discharges. Since no tributaries of considerable volume are located between this station and the proposed crossing located upstream, discharge at the time of construction should be similar to the recorded mean discharge at the station.

Years of Streamflow Record:	1914 to 1923 and 1954 to 2010											
Maximum Daily Discharge:	1,180 m³/s on July 20, 1986											
Minimum Daily Discharge:	0.000 m³/s on February 13, 1922 and January 16, 1923											
Effective Drainage Area:	4,330 km²											

Source: Environment Canada 2013c

The Water Survey of Canada maintains a hydrometric station on the McLeod River near Rosevear, Alberta (Station No. 07AG007) (Environment Canada 2013d). This station is approximately 24 km downstream of the proposed crossing at RK 223.9. Discharge at this station has been recorded every year since 1984. The annual high flow event typically occurs from May to July and flows gradually decline through late summer and fall. Figure 5.3-5 shows that mean monthly flows are lowest in February at 6.29 m³/s and mean flows are highest during the spring freshet with a peak in June at 96.4 m³/s (Environment Canada 2013d). Data for this watercourse are presented in Figure 5.3-5 and Table 5.3-6 and includes maximum, minimum and mean monthly discharges. Since this station records flow information downstream of the proposed crossing, discharge at the time of construction may be slightly less than the recorded mean discharge resulting from smaller tributaries (*e.g.*, Edson River) located between the station and the proposed watercourse crossing.

5.3.2.2 Hargreaves to Darfield Segment

From north to south, the proposed pipeline corridor crosses the Upper Fraser River, Canoe Reach, Upper North Thompson River, Clearwater River and Lower North Thompson River watersheds. The Canoe Reach watershed is part of the Columbia River Basin, while the remaining watersheds form part of the Fraser River Basin (BC ILMB 2013b). There are approximately 349 potential watercourse crossings identified along the proposed pipeline corridor along this segment. Larger watercourses crossed include the upper Fraser River (RK 499.7), Canoe River (RK 531.3), North Thompson River (RK 581.2, RK 619.9 and RK 651.7), Blue River (RK 613.8), Raft River (RK 717.7) and Clearwater River (RK 725.5). A summary of watercourse crossings in the Fraser River Basin and Columbia River Basin along the proposed pipeline corridor for the Hargreaves to Darfield Segment is provided in Section 5.7 Fish and Fish Habitat.

The Fraser River originates in Mount Robson Provincial Park of BC, flowing northwest to Prince George before bending south to the Lower Mainland where it enters the Pacific Ocean after 1,370 km. The Canoe River originates from the Caribou Mountains southwest of the Village of Valemount, BC, and is the only major watercourse crossing within the Columbia River Basin. The Canoe River drains into Kinbasket Lake, a narrow reservoir approximately 190 km long created by the Mica Dam.

The proposed pipeline corridor follows the valley bottom of the North Thompson River for most of its length, crossing the watercourse at three locations. The North Thompson River originates in the Caribou Mountains just outside the east boundary of Wells Gray Provincial Park. The river flows east toward Highway 5, where it bends south, paralleled by the highway and existing TMPL right-of-way for most of its length, until converging with the South Thompson River at the City of Kamloops, BC. The headwaters of the Blue, Raft and Clearwater rivers in the Caribou Mountains are tributaries of the North Thompson River.

The entire length of the Fraser River, from its origins in Mount Robson Provincial Park, to its outflow into the Pacific Ocean at Vancouver, is designated both as a Canadian Heritage River by the Canadian Heritage Rivers System and a BC Heritage River by the BC MOE (BC MOE 2011b, Canadian Heritage Rivers System 2011a). No other designated or nominated Canadian or BC Heritage Rivers are crossed by this segment (BC MOE 2011c, Canadian Heritage Rivers System 2011a).

Surface water allocation in the Province of BC is calculated as overall volume of water for various consumptive and non-consumptive purposes within the entire province (BC MOE 2013a). Although water allocation plans were prepared for specific watercourses in the southern interior and Vancouver Island, no such plans were available for watercourses crossed by the proposed pipeline corridor (BC MOE 2013b).

Hydrostatic test water for the proposed pipeline segment is expected to be withdrawn from the Fraser River, Canoe River and North Thompson River. An estimated 90,000 m^3 of water will be needed to conduct hydrostatic testing of the proposed pipeline along the Hargreaves to Darfield Segment. Water used for hydrostatic testing will be released within the same drainage basin from where it was withdrawn.

Historical Streamflow

The Water Survey of Canada maintains a hydrometric station on the Fraser River at Red Pass, BC (Station No. 08KA007) (Environment Canada 2013e). This station is approximately 27 km upstream of the proposed crossing at RK 499.7. Discharge at this station has been recorded every year since 1955. The annual high flow event typically occurs from June to August and flows gradually decline through late summer and fall. Figure 5.3-6 shows that mean monthly flows are lowest in March at 5.32 m^3/s and mean flows are highest during the spring freshet with a peak in June at 152 m^3/s (Environment Canada 2013e). Data for this watercourse are presented in Figure 5.3-6 and Table 5.3-7 and includes maximum, minimum and mean monthly discharges. Since this station records flow information upstream of the proposed crossing, discharge at the time of construction may be more than the recorded mean discharge resulting from smaller tributaries (*e.g.*, Robson River, Swift Current Creek) located between the station and the proposed watercourse crossing.

Source: Environment Canada 2013e

The Water Survey of Canada maintains a hydrometric station on the Clearwater River near Clearwater Station, BC (Station No. 08LA001) (Environment Canada 2013f). This station is located approximately 2 km upstream of the proposed crossing at RK 725.5. Discharge at this station has been recorded for approximately 73 years between 1914 and 2010. The annual high flow event typically occurs from June to August and flows gradually decline through late summer and fall. Figure 5.3-7 shows that mean monthly flows are lowest in February at 45.3 m^3/s and mean flows are highest during the spring freshet with a peak in June at 714 m^3/s (Environment Canada 2013f). Data for this watercourse are presented in Figure 5.3-7 and Table 5.3-8 and includes maximum, minimum and mean monthly discharges. Although this station records flow information upstream of the proposed crossing, discharge at the time of construction should be similar as the recorded mean discharge since there are only minor tributaries (*e.g.*, Brookfield Creek) located between the station and the proposed watercourse crossing.

The Water Survey of Canada maintains a hydrometric station on the North Thompson River at Birch Island, BC (Station No. 08LB047) (Environment Canada 2013g). This station is located approximately 65 km downstream of the southern-most proposed crossing of the North Thompson River at RK 651.7. Discharge at this station has been recorded every year since 1960. The annual high flow event typically occurs from May to July and flows gradually decline through late summer and fall. Figure 5.3-8 shows that mean monthly flows are lowest in February at 28.1 m^3/s and mean flows are highest during the spring freshet with a peak in June at 444 m^3/s (Environment Canada 2013g). Data for this watercourse are presented in Figure 5.3-8 and Table 5.3-9 and includes maximum, minimum and mean monthly discharges. Since this station records flow information well downstream of the proposed crossing, discharge at the time of construction may be less than the recorded mean discharge as a result of numerous smaller tributaries (*e.g.*, Mad River, Chuck Creek, Montana Creek, Hornet Creek, Cornet Creek, Otter Creek, Ivy Creek, Avola Creek) located between the station and the proposed watercourse crossing.

5.3.2.3 Black Pines to Hope Segment

Located entirely within the Fraser River Basin, from north to south, the proposed pipeline corridor crosses the Lower North Thompson River, Thompson River, South Thompson River, Thompson River, Lower Nicola River and Fraser Canyon watersheds. There are approximately 318 potential watercourse crossings identified along the proposed pipeline corridor for this segment. Larger watercourses crossed include the Thompson River (RK 846.8), Nicola River (RK 928), Coldwater River (RK 957.9, RK 970.3, RK 980 and RK 990) and Coquihalla River (RK 1021.8, RK 1026.5, RK 1028.6, RK 1032.6 and RK 1043.2). A summary of watercourse crossings in the Fraser River Basin along the proposed pipeline corridor for the Black Pines to Hope Segment is provided in Section 5.7 Fish and Fish Habitat.

The Thompson River forms at the confluence of the North and South Thompson rivers at Kamloops, BC. The Thompson River flows into Kamloops Lake approximately 5 km downstream of the proposed crossing, continuing on until joining the Fraser River at the Village of Lytton, BC. The headwaters of the Nicola River originate from the Thompson Plateau west of Kelowna, BC, flowing west through the City of Merritt, at the proposed crossing, before heading northwest until its confluence with the Thompson River at the Community of Spences Bridge. The Coldwater River is a major tributary of the Nicola River, converging several kilometres downstream of the proposed crossing of the Nicola River. Coldwater River generally flows in a northerly direction, originating from the Coquihalla Pass in the Coast Mountains. The proposed pipeline corridor crosses the river at four locations as it winds up the valley, until it reaches the summit of the pass and begins descending down the valley of the Coquihalla River, crossing at five locations before its confluence with the Fraser River near Hope.

No designated or nominated Canadian or BC Heritage Rivers are crossed by the proposed pipeline corridor along this segment (BC MOE 2011c, Canadian Heritage Rivers System 2011a).

Hydrostatic test water for the Black Pines to Hope Segment is expected to be withdrawn from the Thompson River, Coldwater River and Coquihalla River. An estimated 95,000 m^3 of water will be needed to conduct hydrostatic testing of the proposed pipeline along this segment. Water used for hydrostatic testing will be released within the same drainage basin from where it was withdrawn.

<u>Historical Streamflow</u>

The Water Survey of Canada maintains a hydrometric station on the Thompson River at Kamloops, BC (Station No. 08LF023) (Environment Canada 2013h). This station is located approximately 5 km upstream of the proposed crossing at RK 846.8. Water level at this station has been recorded for most months of every year since 1911. Unlike other hydrometric data presented within this subsection that records volume, this station measures water level in metres. The annual high flow event typically occurs from May to July and water levels gradually decline through late summer and fall. Figure 5.3-9 shows that mean monthly water levels are lowest in March at 3.4 m and mean water levels are highest during the spring freshet with a peak in June at 7.1 m (Environment Canada 2013h). Data for this watercourse are presented in Figure 5.3-9 and Table 5.3-10 and includes maximum, minimum and mean monthly water levels. Since no tributaries of considerable volume are located between this station and the proposed crossing located downstream, water level at the time of construction should be similar to the recorded mean water level at the station.

Source: Environment Canada 2013h

The Water Survey of Canada maintains a hydrometric station on the Coquihalla River near Hope, BC (Station No. 08MF003) (Environment Canada 2013i). This station is located within 1 km of the proposed crossing at RK 1043.2. Discharge at this station has been recorded for approximately 36 years sporadically between 1911 and 1983. The annual high flow event typically occurs during May and June and flows abruptly decline during summer, increase during fall and early winter and decline slightly in late winter. Figure 5.3-10 that mean monthly flows are lowest in August at 12 m^3/s and mean flows are highest during the spring freshet with a peak in June at 78.5 m^3/s (Environment Canada 2013i). Data for this watercourse are presented in Figure 5.3-10 and Table 5.3-11 and includes maximum, minimum and mean monthly discharges. Since no tributaries of considerable volume are located between this station and the proposed crossing located downstream, discharge at the time of construction should be similar to the recorded mean discharge at the station.

5.3.2.4 Hope to Burnaby Segment

Located entirely within the Fraser River Basin, from east to west, the proposed pipeline corridor crosses the Fraser Canyon, Harrison River, Chilliwack River and Lower Fraser watersheds. There are approximately 131 potential watercourse crossings identified along the proposed pipeline corridor for this segment. Larger watercourses crossed include the Chilliwack River (RK 1102.3), Sumas River (RK 1114.6), Salmon River (RK 1147.4) and lower Fraser River (RK 1168.9). A summary of watercourse crossings in the Fraser River Basin along the proposed pipeline corridor for the Hope to Burnaby Segment is provided in Section 5.7 Fish and Fish Habitat.

Both the Chilliwack and Sumas rivers originate in Washington State. Flowing northwest across the Canada/US border, the Vedder River joins the Sumas River approximately 8 km downstream of the proposed crossing. The Sumas River continues from the confluence for approximately 3 km before converging with the lower Fraser River. The lower Fraser River is the largest watercourse crossing along the entire length of the proposed pipeline corridor. The Fraser River drains into the Strait of Georgia approximately 30 km downstream of the proposed crossing.

The entire length of the Fraser River, from its origins in Mount Robson Provincial Park, to its outflow into the Pacific Ocean at Vancouver, is designated both as a Canadian Heritage River by the Canadian Heritage Rivers System and a BC Heritage River by the BC MOE (BC MOE 2011b, Canadian Heritage

Rivers System 2011a). No other designated or nominated Canadian or BC Heritage Rivers are crossed by this proposed pipeline segment (BC MOE 2011c, Canadian Heritage Rivers System 2011a).

Hydrostatic test water for the Hope to Burnaby Segment is expected to be withdrawn from the Coquihalla River, Sumas River and Fraser River. An estimated 50,000 m^3 of water will be needed to conduct hydrostatic testing of the proposed pipeline along this segment. Water used for hydrostatic testing will be released within the same drainage basin from where it was withdrawn.

Historical Streamflow

The Water Survey of Canada maintains a hydrometric station on the lower Fraser River at Mission, BC (Station No. 08MH024) (Environment Canada 2013j). This station is located approximately 47 km upstream of the proposed crossing at RK 1168.9. Discharge at this station has been recorded for 32 years since 1965; however, continuous monitoring has only been recorded from 1965 to 1992. The annual high flow event typically occurs from May to July and flows gradually decline through late summer and fall. Figure 5.3-11 shows that mean monthly flows are lowest in February at 1,400 m^3/s and mean flows are highest during the spring freshet with a peak in June at 8,110 m^3/s (Environment Canada 2013j). Data for this watercourse are presented in Figure 5.3-11 and Table 5.3-12 and includes maximum, minimum and mean monthly discharges. Since this station records flow information well upstream of the proposed crossing, discharge at the time of construction will be more than the recorded mean discharge as a result of numerous smaller tributaries (*e.g.*, Pitt River, Stave River) located between the station and the proposed watercourse crossing.

Figure 5.3-11 Historical Mean Monthly Streamflow (m^3/s) Summary for the Lower Fraser River at Mission, BC (Station 08MH024)

5.3.2.5 Burnaby to Westridge Segment

The proposed Segment crosses the Lower Fraser River Watershed within the Fraser River Basin. There is one potential watercourse crossing identified along the proposed pipeline corridor for the Burnaby to Westridge Segment at RK 1182.5.

Historical Streamflow

No hydrometric monitoring stations are identified at watercourses crossed by the Burnaby to Westridge Segment.

5.3.3 Groundwater Quality and Quantity

Groundwater Quality

Groundwater quality depends on the source of the water and the material through which it flows (*e.g.*, sulphate containing clay till, clean sand and gravel), as well as whether the groundwater encounters contamination. Both natural and human influences can affect groundwater quality. Surface water that recharges into the ground can affect groundwater quality; as conversely, groundwater may affect surface water quality. The effects to groundwater quality may be point-source such as a spill or may be much broader in scale such as glacial tills, the time scales over which the effect to groundwater quality varies.

Groundwater Quantity

The flow of groundwater is controlled by gravity and the physical characteristics of the materials through which it flows. Groundwater flow patterns can be affected as a result of natural (*e.g.*, surface water flooding) or human influences (*e.g.*, dewatering, construction of reservoirs).

In the following subsections describing the BC pipeline segments, the term vulnerability in describing aquifers is based on the definition provided by Berardinucci and Ronneseth (2002). They defined the vulnerability of an aquifer as the potential for an aquifer to be degraded. The vulnerability was determined based on:

- depth to the water table – the shallower the water table the greater the vulnerability;
- permeability of materials above the aquifer – the more permeable the sediments the higher the vulnerability; and
- thickness and extent of confining sediments – the less areally extensive and the thinner the confining sediments, the greater the vulnerability.

Tables describing the potential groundwater issues noted for each of the segments are included in the following subsections. A description of the types of potential groundwater issues and why they are a concern is provided in Table 5.3-13.

TABLE 5.3-13

DESCRIPTION OF POTENTIAL GROUNDWATER-RELATED ISSUES ALONG THE PROPOSED PIPELINE CORRIDOR

Potential Type of Groundwater Issue	Description
Creek crossings/deeply incised creek crossings	Related to the increased potential for a trenchless crossing or open cut to compromise the integrity of a confining unit that isolates an underlying productive aquifer (especially in valley bottom). A breach of the confining unit during pipeline construction activities may result in uncontrollable artesian flow at the entry or exit point of the trenchless crossing, or along the alignment in the open cut. This condition may lead to the development of saturated surface conditions and permanent wet conditions in the discharge areas. In addition, loss of circulation that could occur during trenchless crossing may result in drilling fluids entering the creek bed or discharging to surface along the valley slope.
River proximity or crossing/fluvial materials/colluvium in stream	The proposed pipeline corridor lies within alluvial deposits located in proximity to a surface water body. Possible direct hydraulic connection to the surface water body through saturated, coarse-grained alluvial deposits. The saturated alluvial deposits become a direct pathway for pipeline releases to enter the surface water body.

TABLE 5.3-13 Cont'd

Potential Type of Groundwater Issue	Description
Shallow groundwater	Related to the increased potential to experience groundwater discharge in the open excavations by intersecting the water table or comprising the integrity of a shallow confining unit. Groundwater discharging to the pipeline ditch may then be redirected through the higher permeability backfill material, discharging as a new spring at lower elevations.
Shallow well	Related to the increased potential to alter groundwater flow by open excavations, trenchless crossings that intersect the water table or comprising the integrity of a shallow confining unit. Shallow wells completed in this environment may be compromised by the change in the flow system caused by the pipeline construction activity. Shallow wells may be more vulnerable to groundwater impacts caused by pipeline spills.
Spring	Flowing (artesian) conditions indicate increased potential to experience groundwater discharge in the open excavations by intersecting the water table or comprising the integrity of a shallow confining unit. A change in the natural flow system caused by pipeline construction activities may affect natural spring flow.
Unconfined aquifer	Related to the increased potential to alter groundwater flow by open excavations below the water table. A change in the natural flow system caused by pipeline construction activities may affect natural spring flow and shallow wells completed in this environment.
Contaminated shallow aquifer	Existing contamination of unknown extent. Increased potential to alter groundwater flow by open excavations below the water table, leading to redistribution of existing subsurface contamination.

5.3.3.1 Edmonton to Hinton Segment

Ground elevations along the proposed pipeline corridor of the Edmonton to Hinton Segment ascend from approximately 700 m asl near Edmonton to approximately 900 m asl along the western edge of Parkland County. From Parkland County, the proposed pipeline corridor passes into Yellowhead County in west central Alberta and ground elevations increase to approximately 1,400 m asl at Hinton.

Approximately 202 surface water crossings were identified along the proposed pipeline corridor in this segment. Of these, six are being investigated as potential horizontal directional drill (HDD) crossings.

Deeply incised, major watercourse crossings occur at:

- North Saskatchewan River at RK 33.5;
- Pembina River at RK 135.0;
- Wolf Creek at RK 220.6; and
- McLeod River at RK 223.9.

The surficial geology along the proposed pipeline corridor through Parkland and Yellowhead counties is variable, but typically comprises glacial to lacustrine clay deposits that overlie bedrock. Occasional alluvial and fluvial deposits also are mapped along the proposed pipeline corridor (Roed 1970, Shetsen 2002). Unconsolidated deposits are generally reported to be greater than 20 m thick up to approximately RK 128, less than 20 m thick up to RK 226.3, greater than 20-30 m thick from RK 226 to RK 238 and then shallower (less than approximately 10 m thick) to RK 247.

Sand and gravel deposits typically have the highest permeability; these deposits accumulate in fluvial and glaciofluvial depositional environments, following the existing stream and river valleys. Some buried channels have been identified along the proposed pipeline corridor; however, the depth of burial is considered too deep to be disturbed by pipeline construction (1.8-3 m). Silt, sand with clay and gravel with clay deposits tend to have more moderate permeability and may also be found in glaciofluvial and alluvial deposits.

Lacustrine clay and glacial till deposits typically represent low permeability materials that confine the deeper-seated aquifers. Glaciofluvial and alluvial deposits characterized by a clayey matrix can also provide effective barriers to vertical and horizontal groundwater flow. Most water wells extend to bedrock and are completed in regional fractured sandstone units defined as domestic use aquifers. These aquifers are generally confined by low permeability overburden materials and low permeability bedrock shale units. Water wells completed in unconsolidated over burden deposits are usually exploiting local aquifers.

Regional groundwater contamination risk mapping has been interpreted from surficial geology descriptions along the Edmonton to Hinton Segment (Hydrogeological Consultants Ltd. [HCL] 1998, 2004). The risk is high when the near-surface materials are permeable; the risk is low when the near-surface materials are less permeable.

Edmonton obtains its water supply from the North Saskatchewan River. The City of Spruce Grove (approximately RK 58) and the Town of Stony Plain (approximately RK 65) are serviced via a water main from Edmonton. The groundwater contamination risk mapping shows that conditions are generally moderate to high risk of contamination immediately west of Edmonton through to approximately RK 119. The risk of potential contamination becomes generally lower risk with patches of higher risk though to the western border of Parkland County. Of note, Wabamun Lake area is mapped as being at a higher risk of groundwater contamination (HCL 1998). The Village of Wabamun (approximately RK 97) has switched to using groundwater from Wabamun Lake Provincial Park. A pipeline to supply water to the Village of Wabamun from the Town of Stony Plain is currently under construction (During pers. comm.).

In addition, the hamlets of Entwistle (approximately RK 134), Evansburg (approximately RK 136) and Wildwood (approximately RK 150) depend on groundwater.

Aquifers located in Alberta have not been defined in a systematic fashion. The Alberta Geological Survey has identified the Haynes and Sunchild members of the bedrock Paskapoo Formation as aquifers. Possible aquifers in unconsolidated materials along the proposed pipeline corridor in the Edmonton to Hinton Segment were identified as part of this Project. This identification was based on HCL's assessment of areas at risk to groundwater contamination (HCL 1998, 2004), the presence of sand and gravel aggregate, near surface sand and gravel, and the utilization of groundwater through the presence water wells. Table 5.3.14 below lists possible aquifers crossed by the Edmonton to Hinton Segment. The aquifers are presented on the maps for each segment in Appendix A of the Groundwater Technical Report of Volume 5C.

TABLE 5.3-14

POSSIBLE AQUIFERS IN THE EDMONTON TO HINTON SEGMENT

RK	Possible Aquifer Type	Name or Material
RK 33.8 to RK 33.9	Buried valley aquifer (Thalweg)	(none)
RK 36.4 to RK 57.6	Unconsolidated	sand and gravel
RK 62.1 to RK 65.8	Unconsolidated	sand and gravel
RK 67.6 to RK 67.7	Buried valley aquifer (Thalweg)	Drayton
RK 69.2 to RK 79.3	Unconsolidated	sand and gravel
RK 83.2 to RK 85	Unconsolidated	sand and gravel
RK 86.5 to RK 89.8	Unconsolidated	sand and gravel
RK 91.4 to RK 92.8	Unconsolidated	sand and gravel
RK 94.7 to RK 96	Unconsolidated	sand and gravel
RK 97.7 to RK 100.2	Unconsolidated	sand and gravel
RK 103.3 to RK 111.6	Unconsolidated	sand and gravel
RK 112.9 to RK 117.6	Unconsolidated	sand and gravel
RK 121.5 to RK 123.5	Unconsolidated	sand and gravel
RK 121.6 to RK 121.7	Buried valley aquifer (Thalweg)	Onoway
RK 125 to RK 125.4	Unconsolidated	sand and gravel
RK 129.5 to RK 133.9	Unconsolidated	sand and gravel
RK 162.9 to RK 165.3	Unconsolidated	sand and gravel
RK 170.3 to RK 174.1	Unconsolidated	sand and gravel
RK 176.5 to RK 189.4	Bedrock	Sunchild member
RK 184.8 to RK 199.3	Bedrock	Haynes member
RK 185 to RK 186.3	Unconsolidated	sand and gravel
RK 195.3 to RK 198.8	Bedrock	Sunchild member
RK 198.3 to RK 200.2	Unconsolidated	sand and gravel
RK 205 to RK 218.8	Bedrock	Haynes member

TABLE 5.3-14 Cont'd

RK 285 to RK 299.4	Bedrock	Sunchild member

The eastern half of Yellowhead County has a predominantly low risk of contamination grading to moderate or higher risk near the Town of Edson. Between Edson and Hinton, the regional mapping shows that the risk of groundwater contamination is generally high (HCL 2004). Surficial geology mapping through sections of Yellowhead County have identified the presence of organic deposits (muskeg), which may indicate shallow perched groundwater conditions.

The Town of Edson (RK 230) is supplied by groundwater from 10 municipal supply water wells, 2 of which are 80 m (ID No. 481637; currently not in use) and 300 m (ID# 483171; in use) south of the proposed pipeline corridor, while the Town of Hinton relies on the Athabasca River as its water supply source. The rural areas between Edson and Hinton predominantly use groundwater for drinking water and other water use purposes. The well density is considered moderate along the proposed pipeline corridor in the Edmonton to Hinton Segment. Typically, there are very few wells in close proximity of the proposed pipeline corridor.

Potential groundwater-related issues raised as part of the desktop study and subsequent field work for the Edmonton to Hinton Segment is summarized in Table 5.3-15.

TABLE 5.3-15

POTENTIAL GROUNDWATER-RELATED ISSUES IN THE EDMONTON TO HINTON SEGMENT

Location	Potential Groundwater-Related Issue	Summary of Issue	Summary for Field Visited Sites
RK 17.9	Well 85713 - Could have potential groundwater issue, bored stock well, total depth = 14.3 m and water level = 3.2 m below ground level (bgl). Regional geology indicates ice-contacted fluvial deposits.	Shallow well, colluvium	--
RK 24.1 to RK 24.4	Deep Blackmud Creek crossing - colluvial deposits.	Colluvium in stream	--
RK 28.0 to RK 28.2	Deep Whitemud Creek crossing - colluvial deposits.	Colluvium in stream	--
RK 34.4 to RK 34.6	North Saskatchewan River Crossing - colluvial and fluvial deposits.	Colluvium in stream	--
RK 36.8 to RK 37.1	Deep unnamed creek crossing - colluvial deposits.	Colluvium in stream	--
RK 39.6	Well 2093324 - Could have potential groundwater issue, stock well, total depth = 14.3 m and water level = 3.1 m bgl. Regional geology indicates lacustrine deposits.	Shallow well	--
RK 41.6	Well 75019 - total depth = 9.1 m for domestic use. Well 75018 - total depth = 14.0 m for domestic/stock. Potential groundwater because of depth and possible water level.	Shallow well	--
RK 50.9	12 well records related to water table test site near here. Other wells do not indicate groundwater issue; however, the reason for water table test site may cause concern.	Shallow well	--
RK 56.9	Well 81074 - potential groundwater issue. Hand dug domestic/stock use with total depth = 11.6 m and water level = 6.1 m. Just outside 150 m corridor so need to verify location (accuracy only to nearest 400 m). Lacustrine deposits may eliminate concern.	Shallow well	--

TABLE 5.3-15 Cont'd

Location	Potential Groundwater-Related Issue	Summary of Issue	Summary for Field Visited Sites
RK 89.2	Well 459883 - could have potential groundwater issue, bored stock well total depth = 10.4 m and water level = 0.3 m bgl. Shallow ephemeral unknown creek no groundwater concern.	Shallow well	--
RK 90.2	Well 459880 - could have potential groundwater issue, bored stock well total depth = 8.53 m and water level = 1.21 m bgl. Shallow ephemeral unknown creek no groundwater concern.	Shallow well	--
RK 134.9 to RK 135.6	Pembina River Crossing - fluvial deposits.	Colluvium in stream	Steep banks, shallow groundwater likely; 5-10 m overburden over sandstone bedrock.
RK 171.4 to RK 171.5	Lake Crossing - glacial sediments but top of bedrock 7.1 m - potential groundwater concerns.	Shallow well	--
RK 185.3	Shallow Lobstick River crossing - fluvial deposits may cause potential groundwater issue.	Colluvium in stream	--
RK 220.6	Wolf Creek crossing in fluvial deposits - potential groundwater concern.	Colluvium in stream	Poorly-drained; glaciolacustrine silty clayey till.
RK 223.7 to RK 224.1	McLeod River crossing in fluvial deposits - potential groundwater concern.	Colluvium in stream	Shallow groundwater; glaciolacustrine silty clayey till; bedded sandstone.
RK 224.7 to RK 225	Fluvial deposits near the McLeod River.	Colluvium in stream	--
RK 309.1 to RK 311.1	Trail Creek and unknown ephemeral creek crossing in fluvial/alluvium deposits. Full section passes near Athabasca River.	Colluvium in stream	Shallow groundwater: Seepage from glaciofluvial sand and gravel on top of siltstone in river bank exposure.
RK 319.8 to RK 320.1	Hardisty Creek crossing in till near fluvial deposits - potential groundwater concern (approximately 20 m elevation change).	Colluvium in stream	--
RK 327.5 to RK 327.7	Shallow Maskuta Creek crossing in fluvial sediments - most wells deep, but there is spring in area - potential concern.	Colluvium in stream, spring	--
RK 329.5	Shallow wells in glaciofluvial sediments with no confining layers - potential groundwater concern, would have to confirm locations.	Shallow well	--
RK 337.2 to RK 337.5	Two shallow unknown creek crossings in fluvial sediments. Well 485176 in fluvial sediments with no confining layers - potential groundwater concern.	Colluvium in stream	--

More detailed information is provided in Appendix B in the Groundwater Technical Report of Volume 5C.

5.3.3.2 Hargreaves to Darfield Segment

Ground elevations along the proposed pipeline corridor of the Hargreaves to Darfield Segment descend from over 900 m asl near RK 490.0 to approximately 450 m asl at RK 769.0. Groundwater flows generally follow local topography with recharge occurring either directly over the aquifers or from the valley walls (mountain sides) and discharge feeding the local river systems or flowing within fluvial sediments down the valley base.

Approximately 350 surface water crossings were identified along the proposed pipeline corridor in this segment. Of these, eight are being investigated as potential HDD crossings.

Watercourses recommended as potential HDD crossings are summarized below:

- North Thompson River at RK 581.2;
- Blue River at RK 613.8;
- Unnamed channel at RK 619.8;
- Multiple North Thompson River crossings at RK 619.9 and RK 651.6;
- Raft River at RK 717.7;

- Clearwater River at RK 725.5; and
- Mann Creek at RK 735.0.

Maps showing surficial geology from RK 489.7 to RK 636 were considered to be poor quality due to the small scale. From RK 636, however, regional mapping appears underlain by colluvium up to RK 639, which transitions to glacial till bordering fluvial deposits along major drainages. The proposed pipeline corridor passes over predominantly fluvial and glaciofluvial deposits from RK 648 to RK 769 (Fulton 1986, Gough 1987, Tipper 1971). The proposed pipeline corridor intersects short sections of mapped glacial till, colluviums and bedrock through this area; however, most of the well logs reviewed indicated the presence of sand and gravel overlying or bedrock mapped as surface outcrop (BC MOE 2013c).

Additional description of surficial geology for this segment is described in Section 5.1.1.2.

No aquifers have been mapped from RK 490 to RK 524 (from Hargreaves to Valemount). In general, groundwater level depths from RK 490 to RK 524, where reported, are considered moderate (> 6 m bgl), to deep (> 30 m bgl). Few wells are located in the Water Quantity and Quality LSA in this segment. The Valemount Aquifer (#799) is mapped as a glaciofluvial sand and gravel deposit between approximately RK 516 and RK 524.1. This aquifer has been classified in the BC provincial aquifer classification system as having relatively low demand, low vulnerability and a moderate productivity. The average well depth through the area is greater than 28 m bgl. A second glaciofluvial sand and gravel deposit is mapped within the Valemount area, the South Valemount Aquifer (#800) from RK 526 to RK 530. This aquifer is classified as having low demand, low productivity and a moderate vulnerability. The average well depth through this aquifer is greater than approximately 50 m bgl (BC MOE 2013c).

Potentially shallow groundwater areas are noted at a few locations between the Village of Valemount and Community of Blue River (particularly around Blue River), although information on groundwater depths is limited because of the lack of wells in the area (BC MOE 2013c). Aquifer #825 is described as a glaciofluvial sand and gravel deposit mapped near the Community of Blue River. It intersects the proposed pipeline corridor from RK 611.8 to RK 617.5. It is classified as a low demand, moderate productivity and highly vulnerable aquifer (BC MOE 2013c). No aquifers have been mapped between the communities of Blue River and Vavenby, though available information suggests there may be shallow groundwater present along the proposed pipeline corridor. Aquifer #807 is a glaciofluvial sand and gravel deposit extending from the Community of Vavenby to the District of Clearwater. The proposed pipeline corridor intersects Aquifer #807 from RK 698 to RK 717.6. The aquifer is classified as having moderate demand, productivity and vulnerability. Reported well depths are generally deep (> 30 m bgl) and water depths vary from shallow to deep (BC MOE 2013c).

Aquifer #773 is encountered from RK 717.6 to RK 719.4. This aquifer is defined as a glaciofluvial sand and gravel deposit with high demand, moderate productivity and low vulnerability (BC MOE 2013c). The water well density increases substantially around the District of Clearwater. Within the District of Clearwater, the south side of the proposed pipeline corridor encounters Aquifer #772 (a bedrock aquifer with moderate productivity, moderate vulnerability and low demand) and Aquifer #770, described as a sand and gravel deposit with high productivity, demand and vulnerability at RK 723.1. Aquifer #770 transitions to Aquifer #769, described as a sand and gravel deposit with moderate productivity, moderate demand and high vulnerability for a short section of the proposed pipeline corridor. No aquifers are mapped along the proposed pipeline corridor from RK 729.5 to RK 769.0. Reported water levels near the District of Clearwater range from shallow (< 5 m bgl) to moderate (5-30 m bgl) (BC MOE 2013c).

Aquifer #296 has been mapped as an alluvium and alluvial fan (fan shaped deposit of sediment built up by moving water) sand and gravel deposit between RK 748.5 and RK 756.8. The aquifer has low demand and moderate productivity and vulnerability. Aquifer #293 is a second alluvium and alluvial fan sand and gravel deposit mapped south of Clearwater (RK 756.8 to approximately RK 769) (BC MOE 2013c).

There are no community-owned drinking water supply wells in the Village of Valemount, communities of Albreda (RK 545.3), Avola (RK 652.7) and Vavenby (RK 695.7), the District of Clearwater (RK 714.7), Blackpool (RK 726.5) or the Community of Darfield (RK 765). The Community of Blue River (approximately RK 614) is supplied by groundwater (Hughes, Madden pers. comm.); however, the source wells are mapped over 1 km from the proposed pipeline corridor. North Thompson River Provincial Park is supplied by two water wells that are located in proximity to the proposed pipeline corridor. The rural areas between the District of Clearwater and North Thompson River Park are predominantly supplied by groundwater for drinking water and other water use purposes (BC MOE 2013c).

Potential groundwater-related issues raised as part of the desktop study and subsequent field work for the Hargreaves to Darfield Segment are summarized in Table 5.3-16.

TABLE 5.3-16

POTENTIAL GROUNDWATER-RELATED ISSUES IN THE HARGREAVES TO DARFIELD SEGMENT

Location	Potential Groundwater-Related Issue	Summary of Issue	Summary for Field Visited Sites
RK 514.4	Creek crossing.	Creek crossing	--
RK 515.9	Creek crossing.	Creek crossing	--
RK 517.8	Creek crossing.	Creek crossing	--
RK 522.6	Creek crossing, potential shallow groundwater in terrace, unconfined.	Groundwater shallow	Well-drained glaciofluvial sand and gravel.
RK 523.6	Creek and marsh crossing.	Creek crossing	--
RK 531.2	Canoe River crossing; groundwater at or above river level.	Groundwater shallow	Well-drained, sandstone bedrock.
RK 533	Generally swampy area, shallow groundwater.	Groundwater shallow	--
RK 534.4	Creek crossing.	Creek crossing	--
RK 545.8 to RK 545.9	Shallow groundwater.	Groundwater shallow	--
RK 559	Stream crossing, groundwater in alluvium.	Colluvium in stream	--
RK 559	Groundwater in alluvium.	Colluvium in stream	--
RK 561.2	Deep creek crossing.	Deeply incised creek	--
RK 563.4 to RK 563.5	Deep creek crossing.	Deeply incised creek	--
RK 565.9	Deep creek crossing.	Deeply incised creek	--
RK 567.6	Deep creek crossing.	Deeply incised creek	--
RK 571.9	Deep creek crossing.	Deeply incised creek	--
RK 573.5	Creek crossing.	Creek crossing	--
RK 576.3	Creek crossing.	Creek crossing	--
RK 580.3	Deep creek crossing.	Deeply incised creek	Shallow groundwater, well-drained; groundwater seep from bedrock.
RK 581.1	North Thompson River crossing.	River	--
RK 590.3	Creek crossing.	Creek crossing	--
RK 592.9 to RK 593	Creek crossing, alluvial fan.	Colluvium in stream	--
RK 600.2 to RK 600.3	Thunder River crossing.	River	--
RK 611.7 to RK 611.8	Creek crossing, very close to North Thompson River.	Creek crossing	--
RK 613.7	Sand deposits hosting water table aquifer may be used locally - potentially sensitive to contamination.	Groundwater shallow	Shallow groundwater, well-drained, fluvial sand and gravel.
RK 613.8	Blue River crossing.	River	--
RK 619.9	North Thompson River crossing, alluvial terrace high groundwater.	Colluvium in stream	--
RK 621 to RK 622.9	Pipeline corridor close to river in alluvial terrace.	Colluvium in stream	--
RK 622.9 to RK 625.4	Pipeline corridor close to North Thompson River in alluvial terrace, highly sensitive area.	Colluvium in stream	--
RK 625.4 to RK 626.9	Pipeline corridor close to North Thompson River in alluvial terrace, sensitive area.	Colluvium in stream	--
RK 626.6	Froth Creek crossing, potentially seasonal high flow.	Creek crossing	--
RK 634	Very deep creek crossing, may be sensitive to groundwater.	Deeply incised creek	--
RK 638.7	Finn Creek crossing, sand and boulders aquifer, high groundwater level.	Groundwater shallow	--
RK 642 to RK 643.5	Close to braided North Thompson River crossing.	Colluvium in stream	--
RK 645.3 to RK 645.8	Close to North Thompson River crossing.	Colluvium in stream	Poorly-drained, metamorphic bedrock.
RK 646.8 to RK 648.2	Close to North Thompson River crossing.	Colluvium in stream	--
RK 649	Tumtum Creek crossing; alluvial fan.	Colluvium in stream	--
RK 651.3 to RK 651.8	North Thompson River crossing; alluvial terraces.	Colluvium in stream	Shallow groundwater, poorly-drained, fractured metamorphic bedrock.
RK 659.8 to RK 660.7	Very close to North Thompson River in alluvial (?)[1] deposits.	Colluvium in stream	--
RK 663.2 to RK 663.5	Creek bed.	Creek crossing	--

TABLE 5.3-16 Cont'd

Location	Potential Groundwater-Related Issue	Summary of Issue	Summary for Field Visited Sites
RK 668.4 to RK 668.9	Very close to North Thompson River.	Colluvium in stream	--
RK 669 to RK 671.2	Very close to North Thompson River.	Colluvium in stream	--
RK 682.8 to RK 684.2	Close to North Thompson River.	Colluvium in stream	--
RK 706	Wells in proposed pipeline corridor, depth from 20-60 m, aquifer somewhat protected by fine material, low rates.	Shallow well	Glaciofluvial cobbles.
RK 709.6	Close to river, alluvial material (?)[1].	Colluvium in stream	--
RK 711.5	Well in proposed pipeline corridor, close to 50 m dry gravel(?)[1], then water-bearing gravel.	Shallow well	--
RK 713.4	Wells in proposed pipeline corridor, appears as low sensitivity.	Shallow well	--
RK 715.6	River deposits.	Colluvium in stream	--
RK 717.5	Wells in proposed pipeline corridor, low rate to dry(?)[1] somewhat protected by clay and till layers.	Shallow well	Shallow groundwater seepage, glaciofluvial materials to 10 m thick.
RK 725.6 to RK 725.7	Clearwater River crossing, wells in proposed pipeline corridor 30-40 m deep, poorly protected by dirty sand/gravel.	Shallow well	Water well at higher elevation has groundwater depth of approximately 40 m bgl (well is likely 40 m above river), well-drained, likely glaciofluvial, shallow groundwater a possibility.
RK 728.8 to RK 729.5	Blackpool community, shallow wells 6-12 m, water table unprotected aquifer.	Shallow well	--
RK 731 to RK 731.6	Shallow wells 12 m deep, unprotected water table aquifer.	Shallow well	--
RK 734.9 to RK 735.1	Mann Creek crossing, apparently alluvial terrace shallow, water table aquifer.	Colluvium in stream	--
RK 740.7 to RK 740.8	Very close to Lake Lemieux, check geology for material permeability.	Colluvium in stream	--

Note: 1 (?) indicates some uncertainty in the interpretation of imagery and well data.

More detailed information is provided in Appendix B in the Groundwater Technical Report of Volume 5C.

5.3.3.3 Black Pines to Hope Segment

Ground elevations along the proposed pipeline corridor of the Black Pines to Hope Segment increase from approximately 350 m asl at RK 813 to approximately 1,240 m asl at the Coquihalla Summit at RK 1004, then decrease to approximately 60 m asl in the District of Hope at RK 1045.4. Groundwater flows generally follow local topography with recharge occurring either directly over the aquifers or from the valley walls (mountain sides) and discharge feeding the local river systems or flowing within fluvial sediments down the valley base. Portions of the proposed pipeline corridor along the Coquihalla Highway are heavily confined by steep mountain approaches on both sides of the pass.

Approximately 315 surface water crossings were identified along the proposed pipeline corridor in this segment. Of these, seven are being investigated as potential HDD crossings.

Major watercourse crossings are summarized below:

- Thompson River at RK 846.8;
- Nicola River at RK 928.0;
- multiple Coldwater River crossings at RK 957.9, RK 970.3, RK 980.0 and RK 990.0; and
- Coquihalla River at RK 1043.2.

Regional surficial geology mapping by Young (1983) from RK 813 to RK 847.5 is mostly fluvial or glaciofluvial with occasional areas described as colluvium. South of Kamloops (RK 848), the proposed pipeline corridor enters into an area dominated by glacial till and where fluvial or glaciofluvial deposits are only occasionally encountered at stream crossings. From RK 892.6 to RK 934.2, the proposed pipeline corridor crosses glacial till, colluvium, glaciofluvial, fluvial and lacustrine deposits intermittently. Glacial till is the dominant surficial deposit from RK 934.6 to RK 958.8 (Fulton 1986), after which no surficial geology information is available through to the end of this segment. Additional description of surficial geology for this segment is described in Section 5.1.1.3.

Aquifer #283 is mapped in the proposed pipeline corridor from RK 812 to RK 821. This aquifer is described as a modern alluvial fan sand and gravel deposit. It reportedly has low demand and moderate productivity and vulnerability. Water wells reported in the area are generally deep (> 60 m bgl) and water depths are considered to be moderate until RK 820 where shallow water depths are reported. Aquifer #282, an alluvial sand and gravel deposit with moderate demand, moderate productivity and high vulnerability is encountered by the proposed pipeline corridor north of the Thompson River in the Kamloops area from RK 844.7 to RK 846.6. South of the Thompson River, the proposed pipeline corridor crosses a short section of Aquifer #284, an alluvial sand and gravel deposit with similar characteristics as Aquifer #282 (BC MOE 2013c).

Bedrock Aquifer #276 is crossed by the proposed pipeline corridor from RK 851.8 to RK 857.3; this aquifer is classified as having low demand, low productivity and moderate vulnerability. Perched shallow groundwater may be encountered near local surficial water bodies. No aquifers have been mapped from RK 857 to RK 865.7. A second bedrock aquifer, Aquifer #274, is encountered at RK 865.7. Aquifer #274 has similar characteristics as Aquifer #276. No aquifers have been mapped from RK 871.8 to RK 931.1 and little hydrogeological information is available due to the scarcity of water wells. Near the City of Merritt, the proposed pipeline corridor crosses Aquifer #75, described as a sand and gravel deposit with moderate demand, moderate productivity and low vulnerability from RK 931.1 to RK 932.7. Well depths in this area are deep and the groundwater levels are generally variable. No aquifers have been mapped from RK 932.7 to RK 1041.9 (Merritt to Hope). The proposed pipeline corridor crosses Aquifer #1005 from RK 1041.9 to RK 1043.1 as it enters Hope. This aquifer is described as a sand and gravel deposit with moderate demand, moderate productivity and moderate vulnerability. It is underlain by Aquifer #1009, a bedrock aquifer with moderate demand, moderate productivity, but reportedly high vulnerability. Water levels range from shallow to deep in this area. West of RK 1042.9, Aquifer #1007, a sand and gravel deposit with low demand, high productivity and high vulnerability, is mapped within the Water Quantity and Quality LSA.

Well densities are considered high in proximity to the proposed pipeline corridor in the Kamloops, Merritt and Hope areas (BC MOE 2013c). The Kamloops Airport and School District 24 operate drinking water systems in proximity (approximately 400 m and 100 m respectively) to the proposed pipeline corridor. A District of Hope community well and two drinking water system wells are identified in Aquifer #1005 potentially within the proposed pipeline corridor. Spectra Energy Corporation operates a water supply system well near RK 952.8 that lies within 200 m of the proposed pipeline corridor. The Coldwater First Nation's water supply wells are identified in proximity to the existing pipeline corridor and are approximately 1,220 m from RK 642.5 of the proposed pipeline corridor.

Potential groundwater-related issues raised as part of the desktop study and subsequent field work for the Black Pines to Hope Segment is summarized in Table 5.3-17.

TABLE 5.3-17

POTENTIAL GROUNDWATER-RELATED ISSUES IN THE BLACK PINES TO HOPE SEGMENT

Location	Potential Groundwater-Related Issue	Summary of Issue	Summary for Field Visited Sites
RK 844.8 to RK 845.8	North Thompson River terraces, shallow aquifer contaminated by the Kamloops Pump Station.	Contaminations - shallow aquifer	Likely fluvial compact fine clay gravel cobbles; monitoring wells near the Kamloops Pump Station.
RK 846.5 to RK 847.5	North Thompson River crossing, including river terrace with shallow groundwater.	Groundwater shallow	--
RK 858.3 to RK 858.5	Ravine crossing, shallow groundwater.	Groundwater shallow	--
RK 869.7 to RK 870.1	Proposed pipeline corridor encroaching Menanteau Lake; wetland, shallow groundwater.	Groundwater shallow	--
RK 881.7	Very close to Anderson Lake; high groundwater table and connection to lake.	Groundwater shallow	--
RK 910.1	Encroaching wetland.	Creek crossing	--

TABLE 5.3-17 Cont'd

Location	Potential Groundwater-Related Issue	Summary of Issue	Summary for Field Visited Sites
RK 927.8 to RK 928	Nicola River crossing and alluvial terraces; groundwater shallow and connected to river.	Colluvium in stream	Shallow groundwater; poorly-drained, wet.
RK 956.2	Shallow well; aquifer confined but not deep.	Shallow well	Shallow groundwater, well-drained.
RK 957.8 to RK 957.9	Coldwater River crossing; possible terraces with shallow groundwater.	Groundwater shallow	--
RK 963.1 to RK 963.6	Very close to Fig Lake; possible shallow groundwater.	Groundwater shallow	--
RK 970.2 to RK 970.3	Coldwater River crossing and in close proximity to the river.	Colluvium in stream	High electrical conductivity suggests shallow groundwater, well-drained steep till slope failing, 5 m hard till sand and gravel, volcanic bedrock.
RK 980 to RK 980.1	Coldwater River crossing.	River	Shallow groundwater - possible spring in rip-rap, fluvial to glaciofluvial.
RK 1021.8	Coquihalla River crossing, shallow groundwater in alluvial terraces.	Groundwater shallow, colluvium in stream	Shallow groundwater, well-drained glaciofluvial (gravel pit).
RK 1022.9	Dewdney Creek crossing, shallow water in alluvial deposits.	Groundwater shallow	--
RK 1026.5	Coquihalla River crossing.	River	--
RK 1028.6 to RK 1028.7	Coquihalla River crossing, shallow groundwater in alluvium.	Groundwater shallow	--
RK 1032.6	Coquihalla River crossing, shallow groundwater in alluvium.	Groundwater shallow	--
RK 1040.1	Well in the proposed pipeline corridor, shallow and unconfined (unnamed) aquifer.	Shallow well	--
RK 1040.6	Well in the proposed pipeline corridor, shallow (unnamed) aquifers poorly confined and/or not confined.	Shallow well	--
RK 1042.2 to RK 1043.3	Shallow (within 20 m) unconfined (unnamed) aquifer and at end point Coquihalla River crossing.	Unconfined aquifer	Shallow groundwater, well-drained glaciofluvial (gravel pit).

More detailed information is provided in Appendix B in the Groundwater Technical Report of Volume 5C.

5.3.3.4 Hope to Burnaby Segment

Ground elevations along the proposed pipeline corridor of the Hope to Burnaby Segment transition from approximately 60 m asl near the District of Hope to approximately 175 m asl near the City of Burnaby. Groundwater flows will generally follow local topography with recharge occurring directly over the aquifers and discharge feeding the local river systems.

Approximately 131 surface water crossings were identified along the proposed pipeline corridor in this segment. Of these, five have been proposed as potential HDD crossings.

Major watercourse crossings are summarized below:

- Chilliwack/Vedder River at RK 1102.1; 1102.3 and 1102.4;
- Sumas River at RK 1114.6; and
- Fraser River at RK 1168.9.

No surficial geology mapping is available between Hope and Bridal Falls. Regional surficial geology mapping by Armstrong (1980) extends west of Bridal Falls. Armstrong (1980) describes the surficial geology west of Bridal Falls (RK 1079.4 to RK 1085.9) as complex, consisting of Salish bog, swamp and shallow lake deposits consisting of either lowland peat, organic silt loam and silty clay loam (0.3-10 m thick) overlying Fraser River overbank and channel deposits, sandy loam, loamy silt or Salish slope deposits consisting of fan and landslide sand and gravel up to 10 m thick. The surficial geology from RK 1079.4 to RK 1085.9 is summarized in Table 5.3-18. Additional description of surficial geology for this segment is described in Section 5.1.1.4.

TABLE 5.3-18

SURFICIAL GEOLOGY FROM RK 1079.4 TO RK 1085.9

RK Range	Surficial Sediment Description
RK 1079.4 to RK 1080.7	Bog swamp deposits 0.4–10 m thick
RK 1080.8 to RK 1081.5	Slope deposits (sand and gravel) to 10 m thick
RK 1081.6 to RK 1082.2	Channel and overbank deposits (sand and gravel)
RK 1082.2 to RK 1083.3	Slope deposits (sand and gravel) to 10 m thick
RK 1083.3 to RK 1083.9	Bog swamp deposits 0.4-10 m thick
RK 1083.9 to RK 1084.6	Slope deposits (sand and gravel) to 10 m thick
RK 1084.6 to RK 1084.8	Bog swamp deposits 0.4–10 m thick
RK 1084.8 to RK 1085.9	Slope deposits (sand and gravel) to 10 m thick

Source: Armstrong 1980

From RK 1085.9 to RK 1093.9, the material encountered consists of either channel and overbank sediments consisting of silty clay loam or Salish bog, swamp or shallow lake deposits of lowland peat and organic silt loam (Armstrong 1980). From RK 1093.9 to RK 1100.4, the material encountered consists of mountain stream channel and flood plain sediments composed of sand and gravel deposited by the Chilliwack River in Sumas Valley up to 15 m thick (Armstrong 1980). From RK 1100.4 to RK 1108.4, the surficial material consists of stream deposits of sand and gravel up to 15 m thick (Armstrong 1961). From RK 1108.4 to RK 1114.4 (western edge of Sumas Mountain), the proposed pipeline corridor encounters lacustrine deposits consisting of sand up to 4.5 m overlying silt, clayey silt and silty clay (Armstrong 1961). From RK 1114.4 to RK 1121.2, the near surface materials consist of bedrock exposed at Sumas Mountain.

The surficial sediments encountered from RK 1121.2 to RK 1138.2 are variable as shown in Table 5.3-19.

TABLE 5.3-19

SURFICIAL GEOLOGY FROM RK 1121.2 TO RK 1138.2

RK Range	Surficial Sediment Description
RK 1121.1 to RK 1121.7	Slopewash sand to 3 m thick resting on silty clay and clayey silt.
RK 1121.7 to RK 1123.3	Fraser flood plain silty clay and clayey silt up to 9 m thick and overlying sand.
RK 1123.3 to RK 1124.1	Salish swamp deposits (lowland peat) up to 10.6 m thick in most places resting on silty clay and in some places overlying sand and sandy silt.
RK 1124.1 to RK 1128.2	Fraser flood plain silty clay and clayey silt up to 9 m thick and overlying sand.
RK 1128.2 to RK 1129.2	Salish swamp deposits (lowland peat) up to 10.6 m thick in most places resting on silty clay and in some places overlying sand and sandy silt.
RK 1129.2 to RK 1130.1	Glaciolacustrine deposits of silt, clayey silt, silty clay, fine sand and minor coarse sand and gravel.
RK 1130.1 to RK 1130.9	Abbotsford outwash, ice contact, gravel, sand and lenses of till.
RK 1130.9 to RK 1133.4	Glacial Sumas sandy till from less than 1.5 m to 10.6 m thick.
RK 1133.4 to RK 1137.9	Fort Langley Formation (Whatcom) glaciomarine deposits of stony clayey silt and silty clay, clay, silt and sand from 7.6 m to 91.4 m thick.
RK 1137.9 to RK 1138.2	Huntingdon Gravel consisting of gravel and sand up to 30.5 m thick underlying either Sumas till or Whatcom glaciomarine deposits.

Source: Armstrong 1961

West of RK 1140.4, the surficial geology mapping was completed by Armstrong and Hicock (1980). From RK 1140.4 to RK 1145.4, the glaciomarine sediments are referred to as the Fort Langley Formation, which on the older maps was called the Whatcom glaciomarine deposits (Armstrong 1961). The surficial geology from RK 1138.2 to RK 1168.6 (Fraser River Crossing) is described in Table 5.3-20.

TABLE 5.3-20

SURFICIAL GEOLOGY FROM RK 1138.2 TO RK 1168.6

RK Range(s)	Surficial Sediment Description
RK 1138.2 to RK 1144.8	Fort Langley Formation (Whatcom) glacio-marine deposits of stony clayey silt and silty clay, clay, silt and sand from 7.6-91.4 m thick.
RK 1144.8 to RK 1146.3	Salish swamp deposits (lowland peat) up to 10.6 m thick in most places resting on silty clay and in some places overlying sand and sandy silt.
RK 1146.3 to RK 1148.4	Capilano sediments – marine silt loam to clay loam with minor sand and silt and stones to 18.3 m thick.
RK 1148.4 to RK 1150.4	Fraser River deposits – overbank sandy to silt loam to 2 m thick overlying 15 m or more of deltaic channel till (sandy to silt loam).
RK 1150.4 to RK 1151.4; RK 1152.4 to RK 1153.4	Fort Langley Formation - marine silty clay to fine sand. From RK 1151.4 to RK 1152.4 and from RK 1153.4 to RK 1154.4 consists of lowland peat up to 14 m thick overlying Fraser River sediment sandy to silt loam.
RK 1154.4 to RK 1157.6	Sumas drift – proglacial deltaic gravel and sand up to 40 m thick.
RK 1157.6 to RK 1160.1	Capilano sediments mainly marine silt loam to clay loam up to 60 m thick.
RK 1160.1 to RK 1163.6	Salish sediments - lowland peat up to 14 m thick overlying Fraser River sediment sandy to silt loam.
RK 1163.6 to RK 1168.4	Pre-Vashon Quadra fluvial channel fill and marine interbedded fine sand to clayey silt. From RK 1166.4 to RK 1166.4.7 consists of lowland peat up to 14 m thick overlying Fraser River sediment sandy to silt loam.
RK 1168.4 to RK 1168.6	Lowland peat up to 14 m thick overlying Fraser River sediment sandy to silt loam.

Source: Armstrong and Hicock 1980

North of the Fraser River crossing at RK 1168.8, the surficial geology consists of Tertiary bedrock overlain by Vashon Till (Armstrong and Hicock 1980). However, where the proposed pipeline corridor follows valley bottoms, the surficial geology shows much variation, as outlined in Table 5.3-21 below.

TABLE 5.3-21

SURFICIAL GEOLOGY FROM RK 1168.4 TO RK 1176.4

RK Range	Surficial Sediment Description
RK 1168.4.8 to RK 1173	Fraser River overbank deposits of sandy to silt clay loam up to 2 m thick overlying 15 m or more deltaic and channel till sandy to silt loam.
RK 1173 to RK 1173.4	Lowland peat up to 14 m thick overlying Fraser River sediment sandy to silt loam (small amount of Pre-Vashon Quadra fine sand to clayey silt at RK 1173.4).
RK 1173.4 to RK 1176.4	Marine shore and fluvial sand up to 8 m thick.
RK 1176.4 to RK 1179	Vashon Drift and Capilano sediments generally < 8 m thick (from RK 1176.5 to RK 1177.0 consists of marine shore and fluvial sand).
RK 1179 to RK 1179.7 (Burnaby Terminal)	Capilano Sediments – raised beach deposits consisting of poorly-sorted sand to gravel 1-8 m thick.

Source: Armstrong and Hicock 1980

Aquifer #1 is mapped in the Hope area from approximately RK 1045.4 to RK 1051.4. This aquifer is described as a Fraser River Sediments sand and gravel deposit. It reportedly has moderate demand, high productivity and high vulnerability. Water levels reported on records completed for local water wells appear to be shallow to moderate in depth, averaging around 8 m bgl. Aquifer #3 is located immediately south of Hope from approximately RK 1054.5 to RK 1064.5. This aquifer is also a Fraser River sand and gravel deposit with similar characteristics as Aquifer #1 (BC MOE 2013c).

Aquifer #6 extends from RK 1077.2 to RK 1094. This sand and gravel deposit is identified as the Chilliwack-Rosedale Aquifer and is classified as having a low demand, high productivity and high vulnerability. The proposed pipeline corridor is in proximity (approximately 300 m) to several probable drinking water systems with wells in this aquifer including the Tzeachten Indian Reserve (BC MOE 2013c).

Aquifer #8, the Vedder River Fan Aquifer, is located at approximately RK 1094 and is also known locally as the Sardis Aquifer. The Vedder River Fan Aquifer is described as a sand and gravel deposit with high demand, productivity and vulnerability. The City of Chilliwack community wells are located within this aquifer and the mapped well capture zones cross the pipeline proposed pipeline corridor. The proposed pipeline corridor crosses the Vedder River at RK 1102.2 and continues west through Aquifer #8. The Yarrow Waterworks District wells are located within Aquifer #8 on the south side of the Vedder River, more than 800 m from the proposed pipeline corridor. The proposed pipeline corridor continues to overlie Aquifer #8 through to Aquifer #21, the Sumas Prairie Aquifer in Abbotsford. Aquifer #21 is described as a sand and gravel deposit with moderate demand, productivity and vulnerability. No aquifers are mapped from RK 1114.4.2 to RK 1121.1 (BC MOE 2013c).

The proposed pipeline corridor passes briefly across a series of saturated sand and gravel deposits defined as aquifers between the cities of Abbotsford and Surrey (BC MOE 2013c).

1. Aquifer #22 extends from RK 1121.1 to RK 1129.9 and is a regionally extensive, sand and gravel deposit classified as having low demand, low moderate productivity and low vulnerability. Water levels in this aquifer range from shallow to moderate depth. The Stó:lō Nation and another potential drinking water system are located near RK 1127.6.
2. Aquifer #16 extends from RK 1129.9 to RK 1130.9 and is a Sumas Drift sand and gravel deposit with low demand, low to moderate productivity and high vulnerability. Water levels in this aquifer range from shallow to moderate depth. There is a high density of wells in proximity to the proposed pipeline corridor in this area.
3. Aquifer #27 extends from RK 1130.6 to RK 1132.4 and is mapped as a Fort Langley Formation sand and gravel deposit with high demand, high productivity and low vulnerability. Water levels in this aquifer range from moderate to deep. There is a high density of wells in proximity to the proposed pipeline corridor in this area.
4. Aquifer #29 does not cross the proposed pipeline corridor, but is located within the Water Quantity and Quality LSA. This aquifer is described as a Fort Langley Formation sand and gravel deposit with low demand, low vulnerability and moderate productivity. Water levels in this aquifer range from moderate to deep. There is a high density of wells in proximity to the proposed pipeline corridor in this area.
5. Aquifer #30 extends from RK 1132.4.5 to RK 1133.4.5 and is mapped as a Fort Langley Formation sand and gravel deposit with low demand, moderate productivity and high vulnerability. Water levels in this aquifer range from moderate to deep. There is a high density of wells in proximity to the proposed pipeline corridor in this area.
6. The proposed pipeline corridor crosses back over Aquifer #27 at RK 1135.7.
7. Aquifer #32 extends from RK 1138 to RK 1138.9 and is described as a sand and gravel deposit with moderate demand, moderate productivity and low vulnerability. Water levels in this aquifer range from moderate to deep. There is a high density of wells in proximity to the proposed pipeline corridor in this area.
8. Aquifers #35 (Hopington) and #36 do not cross the proposed pipeline corridor, but are located within the Water Quantity and Quality LSA. Both aquifers are described as sand and gravel deposit with high vulnerability. The Hopington Aquifer has been identified as in intensive use for water supply with declining water levels and increasing nitrate concentrations.
9. Aquifer #58 (Nicomeki-Serpentine) extends from RK 1145.4 to RK 1159.7 and is a sand and gravel deposit with moderate demand, moderate productivity and low vulnerability. Several potential drinking water systems owned by the Township of Langley and a Langley school, among others, were identified. Water levels in this aquifer range from shallow to moderate depths. There is a high density of wells in proximity to the proposed pipeline corridor in this area.
10. Aquifers #59 and #60 also underlie the proposed pipeline corridor through this segment. Both aquifers are classified as low vulnerability.
11. Aquifer #61 extends from RK 1163.4 to RK 1165.4 and from RK 1167.8 to RK 1168.4, and is described as a Quadra Sand aquifer with low demand, low vulnerability and high productivity. Water levels in this aquifer range from shallow to moderate depths. There is a high density of wells in proximity to the proposed pipeline corridor in this area including potential drinking water system wells owned by Mountford, Corporation of Surrey, the GVRD and numerous commercial/industrial names.
12. Aquifer #48 underlies the proposed pipeline corridor from RK 1165.4 to RK 1167.8 and from RK 1166.4 to the Fraser River at RK 1168.6. This aquifer is described as a sand and gravel deposit

with low demand and moderate productivity and vulnerability. Few water wells are located in this area.

13. Aquifer #46 extends from RK 1169.1 close to the Fraser River to RK 1173.2 and is described as a sand and gravel deposit with low demand, moderate productivity and high vulnerability. Few water wells are located in this area.
14. Aquifer #49 extends from RK 1173.2 to RK 1179.4 at the southern edge of the Burnaby Terminal and is described as a sand and gravel deposit with low demand and moderate vulnerability. Burnaby is supplied by GVRD water from a remote surface water source and few wells are identified in the area.

Potential groundwater-related issues raised as part of the desktop study and subsequent field work for the Hope to Burnaby Segment is summarized in Table 5.3-22.

TABLE 5.3-22

POTENTIAL GROUNDWATER-RELATED ISSUES IN THE HOPE TO BURNABY SEGMENT

Location	Potential Groundwater-Related Issue	Summary of Issue	Summary for Field Visited Sites
RK 1047.6	Shallow (within 20 m) unconfined aquifer. RK in the mid-point of well field.	Unconfined aquifer	--
RK 1049.3 to RK 1051.6	Shallow (within 30 m) unconfined aquifer. Wells in the proposed pipeline corridor.	Unconfined aquifer	--
RK 1054.6 to RK 1062.8	Poorly confined to unconfined, shallow (within 10 m) aquifer along the corridor; high production rates up to 800 gallons per minute (pgm); 2 creek crossings.	Unconfined aquifer	Well-drained, moderate to high permeability, shallow groundwater, surface seepage, coarse sand and silt; domestic well noted.
RK 1057.6	Two wells within the proposed pipeline corridor, somewhat confined, no particular concerns.	Shallow well	--
RK 1062.8 to RK 1065.1	Poorly confined to unconfined aquifer within 20 m, high production rates likely.	Unconfined aquifer	--
RK 1077.3 to RK 1089.9	Potentially confined aquifer, 20-30 m thick. A few wells identified. Low to medium concerns.	Unconfined aquifer	--
RK 1080.1 to RK 1083.1	Entire length of corridor over an unconfined, prolific aquifer; 20-30 m thick. Numerous wells identified.	Unconfined aquifer	--
RK 1089.9 to RK 1094.2	Shallow sandy aquifer, top at 8-10 m, mostly unconfined, high rates. Entire area should be classified sensitive.	Unconfined aquifer	--
RK 1094.2 to RK 1094.9	Chilliwack/Vedder Aquifer; sensitive zone.	Unconfined aquifer	New subdivision - could have wells, coarse, sandy till, cobbles.
RK 1094.9 to RK 1097.9	Shallow sandy aquifer, top at 810 m, mostly unconfined, expected high production rates. Entire area should be classified sensitive; no wells marked in corridor.	Unconfined aquifer	--
RK 1097.9 to RK 1101.1	Chilliwack/Vedder Aquifer; sensitive zone.	Unconfined aquifer	--
RK 1101.2 to RK 1104.7	Chilliwack/Vedder Aquifer; sensitive zone, no confining layers, shallow; Chilliwack/Vedder River crossing at RK 1102.6.	Unconfined aquifer	--
RK 1104.7 to RK 1107.5	Chilliwack/Vedder Aquifer; sensitive zone, no confining layers, shallow.	Unconfined aquifer	--
RK 1114.6 to RK 1114.7	Sumas River crossing.	River	--
RK 1147.4	Wells in the proposed pipeline corridor; deeper confined aquifer at 60+ m bgl. Salmon River crossing at RK 1147.8.	Shallow well	--
RK 1159	Numerous wells in the corridor; some dry, some 120 m deep, some very shallow (< 20 m). High to medium sensitivity.	Shallow well	--
RK 1168.6 to RK 1169.3	Fraser River crossing.	River	--

More detailed information is provided in Appendix B in the Groundwater Technical Report of Volume 5C.

5.3.3.5 Burnaby to Westridge Segment

No surface water crossings have been identified along the proposed pipeline corridor and no trenchless crossings are proposed through this segment.

Ground elevations decrease from approximately 175 m asl at Burnaby to 0 m asl at the Westridge Marine Terminal. Groundwater flows generally follow local topography with recharge occurring directly over the aquifers and discharge feeding the local river systems and Burrard Inlet.

Regional surficial geology for the Burnaby to Westridge Segment is summarized in Table 5.3-23.

TABLE 5.3-23

SURFICIAL GEOLOGY FROM RK 0 to RK 3.6
ALONG THE BURNABY TO WESTRIDGE SEGMENT

RK Range	Surficial Sediment Description
RK 0 to RK 1	Capilano Sediments – raised beach deposits consisting of poorly sorted sand to gravel 1-8 m thick.
RK 1 to RK 2.8	Vashon Drift and Capilano sediments generally < 8 m thick but up to 25 m thick of till and interbeds of glaciofluvial sand to gravel.
RK 2.8 to RK 3.6 (Westridge Marine Terminal)	Undivided pre-Vashon till, glaciofluvial and marine sediments.

Source: Armstrong and Hicock 1980

Additional description of surficial geology for this segment is described in Section 5.1.1.5.

Aquifer #49 is mapped in the Burnaby area from RK 1.7 to RK 3.5. This aquifer is described as a Quadra Sands deposit with low demand, moderate productivity and vulnerability. Burnaby is supplied by GVRD water from a remote surface water source and few wells are identified in the area.

No additional aquifers are identified between RK 3.5 and the Westridge Marine Terminal at RK 3.6. More detailed information is provided in Appendix B in the Groundwater Technical Report of Volume 5C.

5.4 Air Emissions

This subsection discusses the existing air quality conditions along the proposed pipeline corridor. The indicators selected for this element discussed below include:

- primary emissions of CACs (PM, CO, NO_2 and SO_2) and VOCs (BTEX);
- secondary smog-related products (ozone and $PM_{2.5}$);
- H_2S and mercaptans (odour potential); and
- fugitive emissions from pump stations (discussed in Section 6.0).

The rationale for the selection of indicators is provided in Section 7.2.4. The potential Project-related effects and mitigation pertaining to air emissions arising from construction and operation of the proposed pipeline are discussed in Section 7.2.4. Refer to the Pipeline and Facilities Air Quality and Greenhouse Gas Technical Report of Volume 5C for additional details on the existing ambient air quality conditions.

This setting discusses the existing ambient air quality conditions within the Air Quality RSA, which is the area where the direct and indirect influences of other activities could overlap with the Project-specific effects from the pipeline and cause cumulative effects on the air quality indicators. The Air Quality RSA consists of a 5 km wide band generally extending from the Footprint (*e.g.*, 2.5 km on both sides of the Footprint). The spatial boundaries of the Air Quality RSA are shown on Figures 5.4-1 to 5.4-4, along with the spatial boundaries of the Acoustic Environment RSA (Section 5.6).

5.4.1 General Overview of Air Quality

The Project setting for air quality is characterized based on a review of historical measurements of ambient concentrations along the pipeline corridor. Meteorological conditions along the pipeline corridor were also reviewed as meteorological conditions determine how airborne contaminants are transported and dispersed in the atmosphere.

Historical ambient monitoring data were collected from the Clean Air Strategic Alliance (CASA), the BC MOE, Metro Vancouver and Environment Canada's National Air Pollution Surveillance (NAPS) Program. The proposed pipeline corridor was divided into 11 areas for the purpose of characterizing ambient concentrations along the corridor and a number of stations were selected to represent each area. A summary of the air quality stations selected and the parameters monitored are shown in Table 5.4-1. Parameters monitored include PM, CO, nitrogen dioxide (NO_2), SO_2, H_2S, total reduced sulphur (TRS), ozone and BTEX.

TABLE 5.4-1

LIST OF AIR QUALITY STATIONS ALONG THE PROPOSED PIPELINE CORRIDOR

Pipeline Segment	Station ID	Station Name	Data Source	Latitude/Longitude (Decimal Degrees)	Elevation (m)	Parameters Monitored	Period of Data
Edmonton to Hinton	*Edmonton Area* (*surrounding Edmonton Terminal*)						
	1a	Edmonton East	CASA (ID 1029)	53.548, -113.368	679	$PM_{2.5}$, CO, NO_2, SO_2, H_2S, ozone	2002 to 2011
	1b	Edmonton East	NAPS (ID 90121)	53.548, -113.368	670	BTEX	2002 to 2011
	2a	Edmonton Central	CASA (ID 1028)	53.544, -113.499	663	$PM_{2.5}$, CO, NO_2, ozone	2002 to 2011

Notes:

1. The NAPS website identifies this station to be Chilliwack Works Yard but it is located at the Chilliwack Airport.
2. $PM_{2.5}$ data is missing from January to April 2007; data completeness is 77%.
3. PM_{10} data is missing in 2009; data completeness is 85%. $PM_{2.5}$ data is missing from September to December 2008; data completeness is 77%.
4. SO_2 data is missing from May to November 2002; data completeness is 92%.

5.4.1.1 Edmonton to Hinton Segment

Meteorological Conditions

Most of Alberta has a semi-arid continental climate, characterized by warm summers and cold winters. Arctic air masses in the winter and continental air masses in the summer result in large temperature variability throughout the year. Located in the “rain-shadow” of the Rocky Mountains, the proposed pipeline corridor between Edmonton and Hinton tends to receive little precipitation. Meteorological conditions for this segment are discussed in Section 5.1.3.1.

Monthly visibility data, based on 30 year climate normals at the Edmonton International Airport, are shown in Table 5.4-2. November has the most hours with the lowest visibility while July has the most hours with the highest visibility. Deep temperature inversions in the winter months along with calm conditions can create a layer of cold, stagnant air near the ground. This, along with increased fuel consumption and vehicle idling during cold spells, can lead to conditions that will lead to low visibility. Quite often in Edmonton, these conditions usually occur when a warm front approaches, trapping emissions close to the surface. Edson Airport climate normal visibility readings are summarized in Table 5.4-3. Similar to Edmonton, visibility at Edson is greater in the summer than in the winter. Reduced visibility in the winter is likely due to deep temperature inversions along with increased NO_2 concentrations, which is a large contributor to light absorption in the atmosphere.

TABLE 5.4-2

5.4.1.2 Hargreaves to Darfield Segment

Meteorological Conditions

The proposed pipeline corridor between Hargreaves and Darfield is located in the Rocky Mountains which tend to experience longer and sometimes colder winters. Moisture-laden air masses from the coast of BC travel upslope and are forced to cool, generating heavy precipitation over the mountains. Meteorological conditions for this segment are discussed in Section 5.1.3.2.

There are no visibility observation data available for the Hargreaves to Darfield Segment.

5.4.1.3 Black Pines to Hope Segment

Meteorological Conditions

Located east of the Coast Mountains, the Black Pines to Hope Segment has a drier and more continental climate with warm dry summers and cool winters. The southern interior region commonly experiences BC's hottest summers. Meteorological conditions for this segment are discussed in Section 5.1.3.3.

Kamloops experiences the most hours with low visibility in January and the most hours with high visibility in July, as shown in Table 5.4-4. Reduced visibility in the winter is possibly due to higher NO_2 concentrations observed during this time.

TABLE 5.4-4

MONTHLY VISIBILITY OBSERVATIONS FROM KAMLOOPS AIRPORT CLIMATE NORMALS, 1971 TO 2000

Visibility	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Annual

5.4.1.4 Hope to Burnaby and Burnaby to Westridge Segments

Meteorological Conditions

The climate along the Hope to Burnaby and Burnaby to Westridge segments in the Lower Fraser Valley is known as an oceanic, or west coast, climate, characterized by mild temperatures with little seasonal variability. Rainfall dominates the winter in this region due to cyclonic low-pressure systems from the North Pacific. Meteorological conditions for this segment are discussed in Section 5.1.3.4.

The City of Abbotsford experiences the most hours with low visibility in October and the most hours with high visibility in July, as shown in Table 5.4-5. Reduced visibility in October may be a result of elevated VOC concentrations in October. Greater visibility in the summer corresponds to months with the least precipitation that can cause light scattering.

TABLE 5.4-5

MONTHLY VISIBILITY OBSERVATIONS FROM ABBOTSFORD AIRPORT CLIMATE NORMALS, 1971 TO 2000

Visibility	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Annual
Hours with < 1 km	22.2	13.4	4.7	1.3	0.4	1.3	1.6	6.1	14.2	29.2	10.1	21.5	126.1

Source: Environment Canada 2013l

Monthly visibility readings based on climate normals from the Vancouver International Airport are shown in Table 5.4-6. The most hours with low visibility are observed in January, whereas, the most hours with high visibility are observed in July. This corresponds with the precipitation regime in the area. There may also be some correlation with elevated NO_2 and VOC concentrations in the winter.

TABLE 5.4-6

MONTHLY VISIBILITY OBSERVATIONS FROM VANCOUVER INTERNATIONAL AIRPORT CLIMATE NORMALS, 1971 TO 2000

Visibility	Jan.	Feb.	March	April	May	June	July	Aug.	Sept.	Oct.	Nov.	Dec.	Annual

5.4.2 Criteria Air Contaminants and Volatile Organic Compounds

CACs are a group of commonly found contaminants typically formed from combustion for which there are ambient air quality criteria, including PM, CO, NO_2 and SO_2. Observed CAC concentrations for 2011, or the most recent year if 2011 was not available, are summarized in Figures 5.4-5 to 5.4-9. No exceedances of the air quality objectives for CO, NO_2 or SO_2 were observed in 2011. Some exceedances of PM_{10} and $PM_{2.5}$ were observed infrequently. Overall, existing air quality conditions along the proposed pipeline corridor, with respect to CAC concentrations, was very good with few exceedances of the relevant ambient air quality objectives. Each area is discussed separately in more detail in the following subsections.

VOCs are a group of organic compounds with sufficiently high vapour pressures under ambient conditions to evaporate from the liquid form of the compound and enter the surrounding air, and participate in atmospheric photochemical reactions. Of particular interest are BTEXs, typical VOCs found in petroleum derivatives, also collectively known as BTEX. Existing BTEX concentrations along the proposed pipeline corridor were analyzed based on a review of historical ambient monitoring data from Environment Canada's NAPS network. BTEX is primarily measured at more urban or populated areas where ambient air quality is a greater concern. Areas for which BTEX data are available are discussed in the following subsections. For all other areas, the main sources of BTEX emissions is the use of gasoline in vehicles and agricultural equipment, occasional biomass burning from land clearing or other activities, and occasional forest fires in the summer. The magnitude of BTEX concentrations in these areas are expected to be relatively low compared to BTEX concentrations in the more urban and/or industrialized areas for which there are BTEX monitoring results.

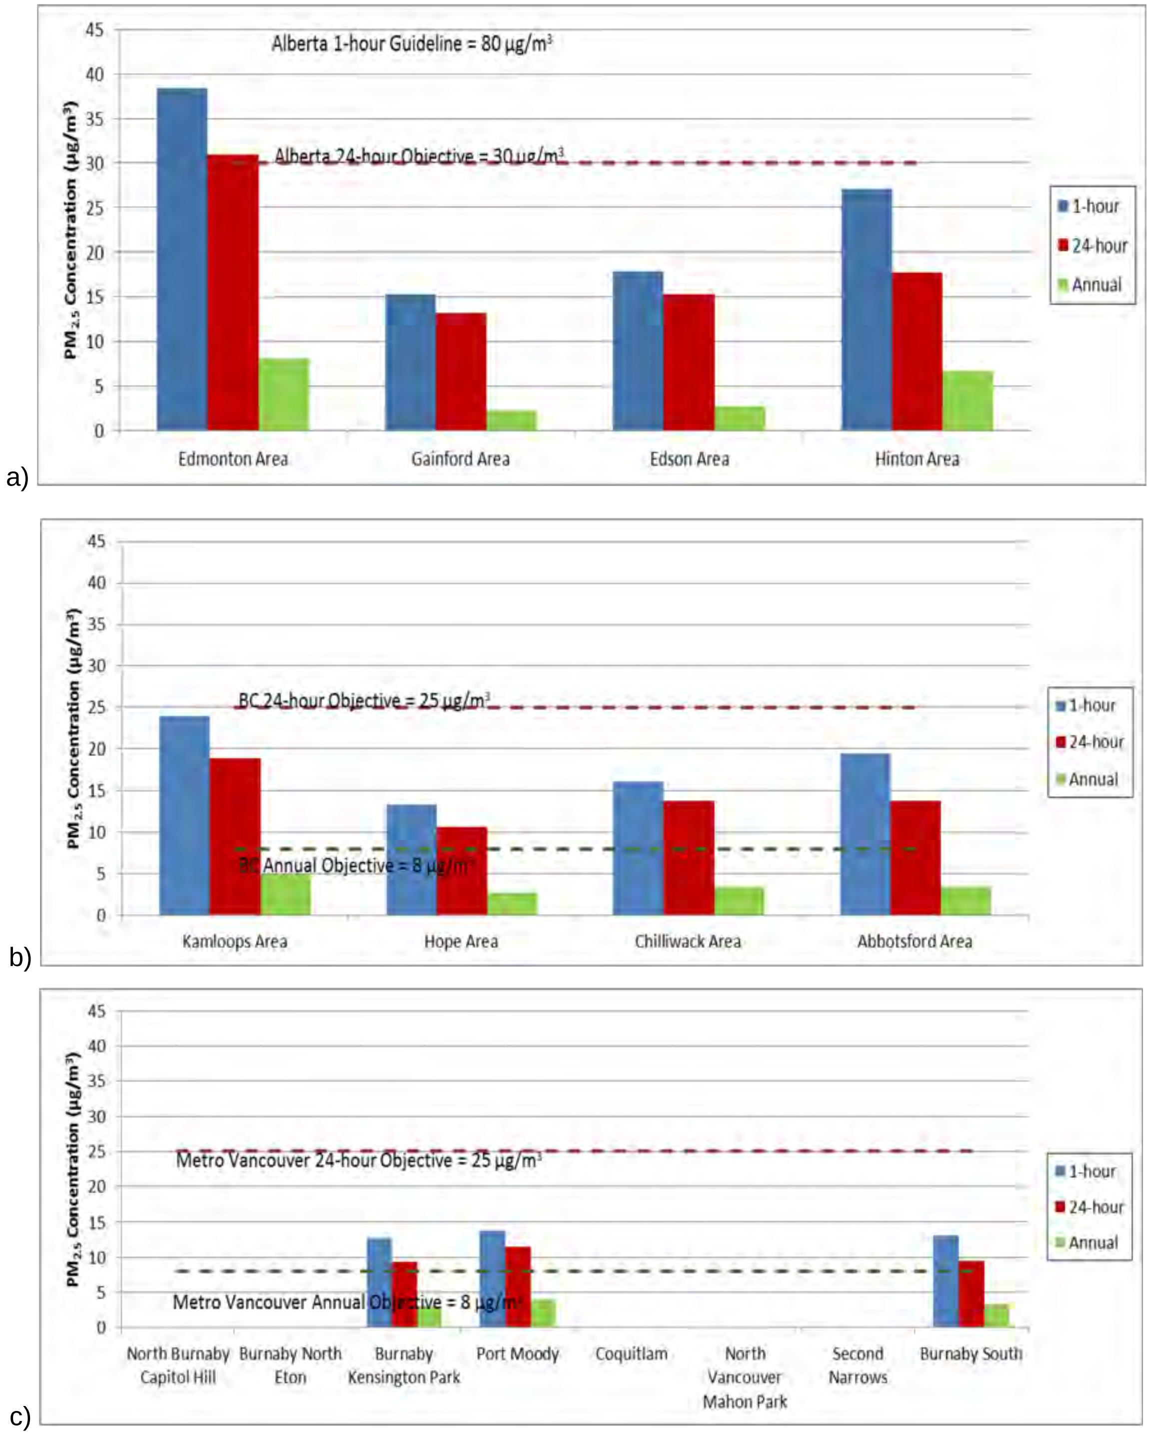
Figure 5.4-5 Observed PM_{10} concentrations in 2011 for (a) Alberta, (b) BC, Outside Metro Vancouver and (c) Metro Vancouver (in µg/m[3])

a)
b)
c)

Notes: There was no PM_{10} data from the Gainford and Hinton areas in 2011. Data from 2008 and 2009 respectively are presented.

There are no PM_{10} objectives for Alberta and, therefore, the BC objective is shown to place observed concentrations in context. There is no annual PM_{10} objective in BC.

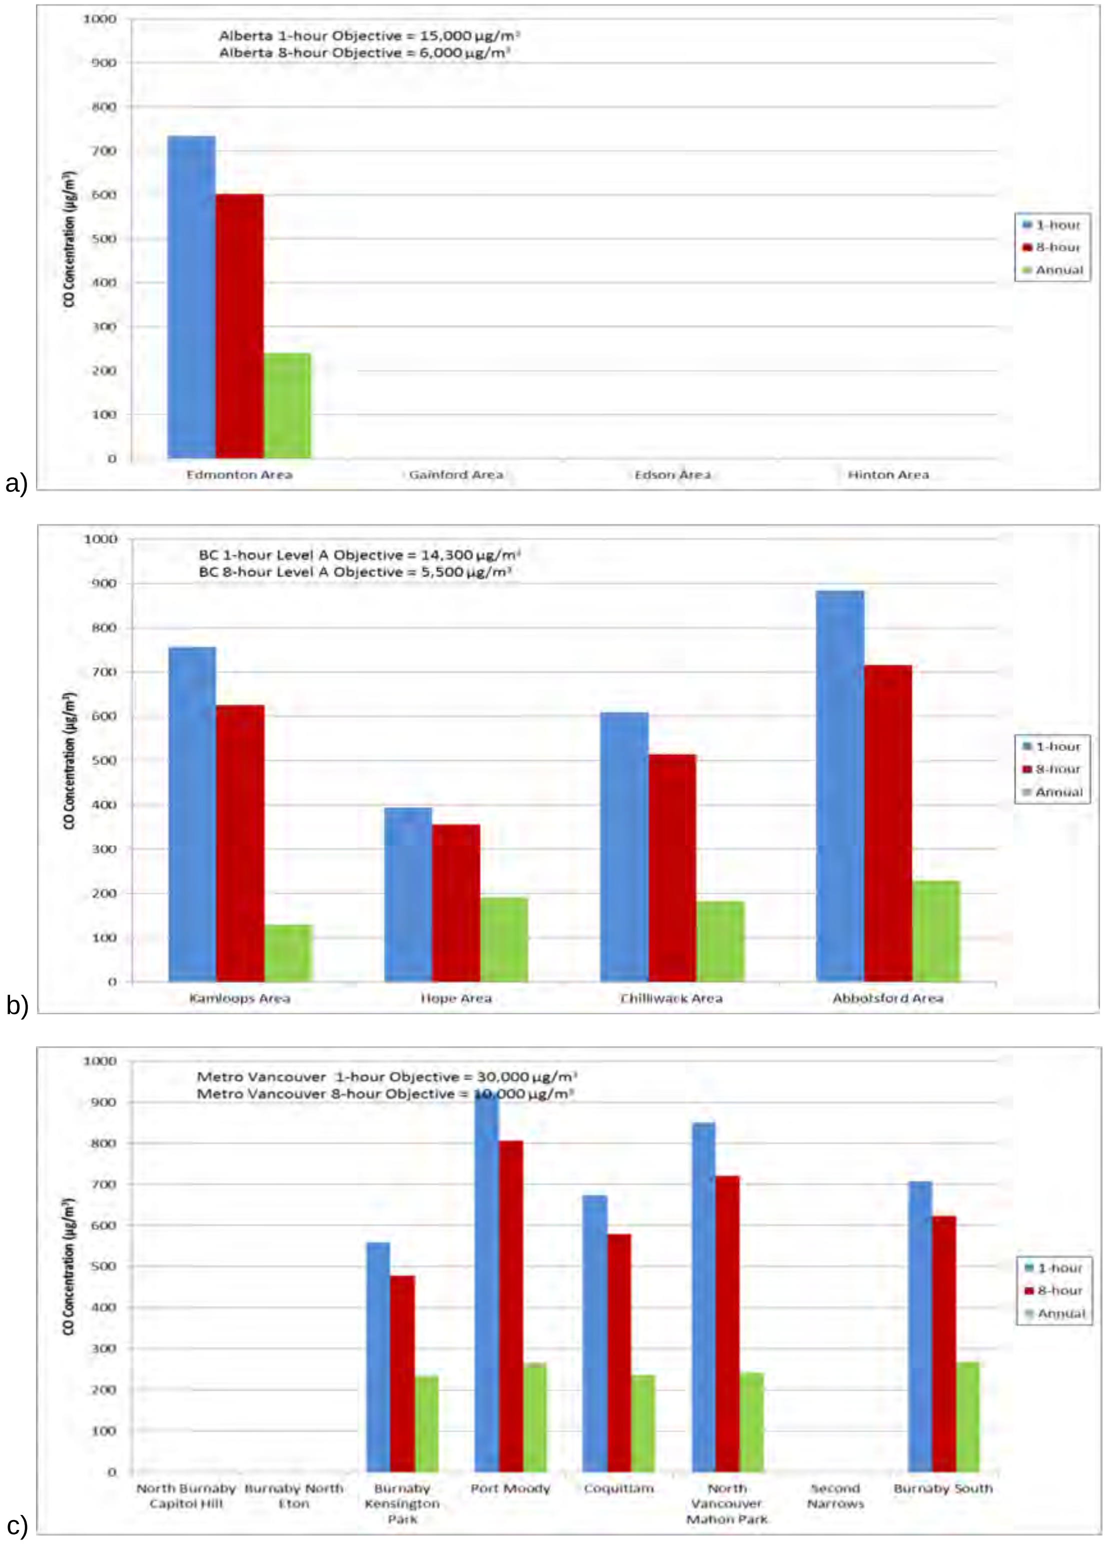
Figure 5.4-6 Observed $PM_{2.5}$ concentrations in 2011 for (a) Alberta, (b) BC, Outside Metro Vancouver and (c) Metro Vancouver (in µg/m^3)



Notes: There is no $PM_{2.5}$ data from the Abbotsford area in 2011. Data from 2009 are presented.

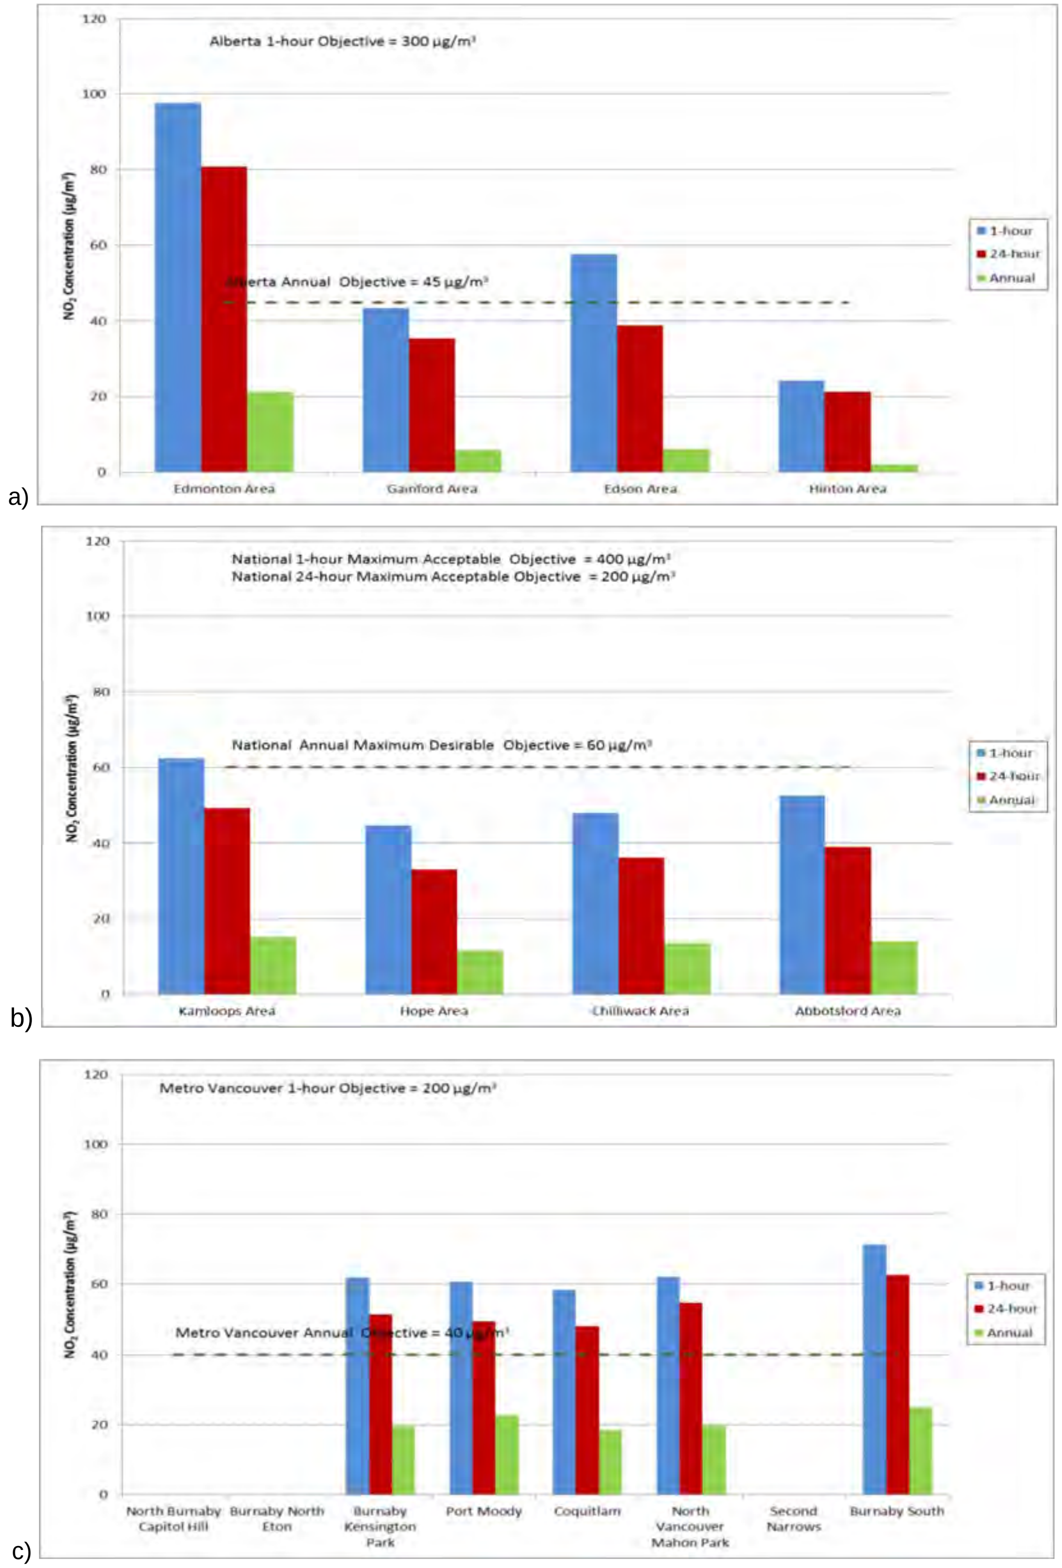
There is no 1 hour $PM_{2.5}$ objective in BC or Metro Vancouver.

Figure 5.4-7 Observed CO concentrations in 2011 for (a) Alberta, (b) BC, Outside Metro Vancouver and (c) Metro Vancouver (in µg/m^3)



Notes: There is incomplete CO data from the Kamloops area in 2011. Data from 2010 are presented.
There is no annual CO objective in Alberta, BC or Metro Vancouver.

Figure 5.4-8 Observed NO_2 concentrations in 2011 for (a) Alberta, (b) BC, Outside Metro Vancouver and (c) Metro Vancouver (in µg/m^3)



Notes: There are no provincial NO_2 objectives in BC; national objectives are applicable.
There is no 24 hour NO_2 objective in Alberta or Metro Vancouver.

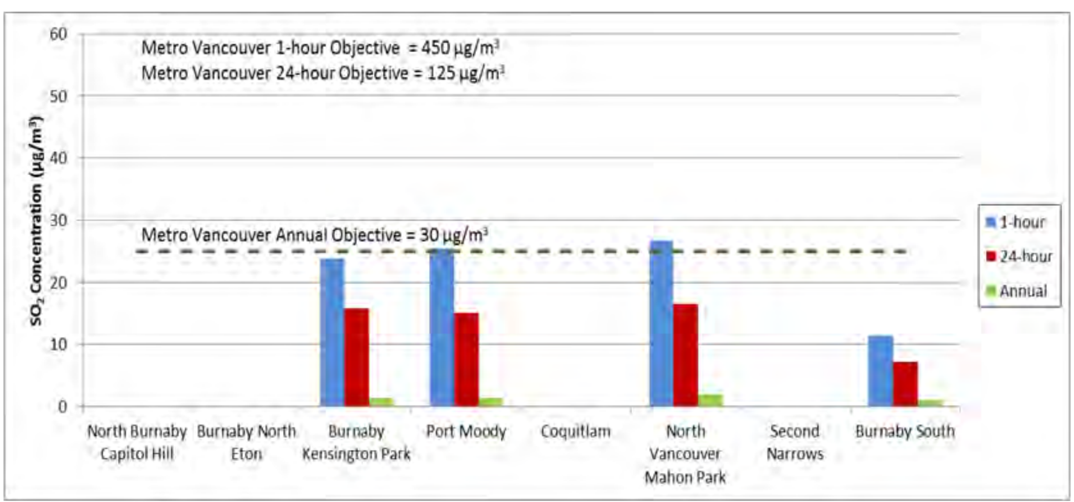
b)



c)

Notes: There is no 24 hour SO_2 objective in Alberta; there is a 30 day objective instead.
There is no equivalent 30 day SO_2 objective in BC or Metro Vancouver.

5.4.2.1 Edmonton to Hinton Segment

There are four main areas in which ambient monitoring data are available along the Edmonton to Hinton Segment: in and around the City of Edmonton; Hamlet of Gainford; Town of Edson; and Town of Hinton. With the exception of PM_{10}, the highest CAC concentrations along the Edmonton to Hinton Segment were observed in the Edmonton area. This is primarily attributable to urban emissions in the area such as residential heating and traffic. The highest PM_{10} concentrations along the Edmonton to Hinton Segment and along the proposed pipeline corridor were observed at the Hinton monitoring station and are likely attributable to nearby industrial sources such as the West Fraser Mills pulp and paper plant. These high concentrations are likely localized to the Town of Hinton and are expected to be lower in the surrounding area.

With the exception of the Hinton area, existing air quality along the Edmonton to Hinton Segment with respect to PM concentrations are generally good, with rare exceedances of the Alberta ambient air quality objectives for $PM_{2.5}$, occurring up to 1% of the time in the Edmonton area. Occasional high levels of PM may be attributable to increased traffic along nearby roads and/or activities at nearby industrial and construction sites. Long range transport of PM related to smoke from large forest fires have also been attributed to elevated PM levels over Edmonton during the summer. With respect to CO, NO_2 and SO_2 concentrations, existing air quality conditions are very good along the entire segment. There were no exceedances of the Alberta ambient air quality objectives for CO, NO_2 and SO_2.

BTEX measurements in the Edmonton area are available from the Edmonton East and Edmonton Central NAPS stations. For most years, concentrations at Edmonton East tended to be higher than those at Edmonton Central. Maximum concentrations for the Edmonton East station ranged from 15.6-116.1 $\mu g/m^3$ over the 10 year period from 2002 to 2011. High BTEX levels at the Edmonton East station are expected to be attributable to nearby industrial sources, most notably, the Suncor Energy and Imperial Oil refineries.

In the Hinton area, BTEX measurements are available from the Hightower Ridge NAPS station, which measured BTEX concentrations from June 2003 to June 2004. Observed BTEX concentrations ranged from 0.2 $\mu g/m^3$ to 2.6 $\mu g/m^3$ over the 1 year period. Due to the high elevation of the Hightower Ridge station and the absence of nearby emission sources, BTEX observations at this station may be somewhat lower than ambient BTEX concentrations near the proposed pipeline corridor and related pump stations.

5.4.2.2 Hargreaves to Darfield Segment

Based on the nearby emission sources, it is expected that existing air quality conditions along the Hargreaves to Darfield Segment are generally very good. There may be higher PM levels in the vicinity of a sawmill located approximately 50 km northwest of the Blackpool Pump Station, but these are expected to decrease rapidly with distance. PM concentrations near the communities of McLure and Blue River may be higher during the winter due to emissions from wood-burning appliances. Beyond that, there may be occasional episodes of high PM concentrations from forest fires in the region. Ambient concentrations of CO, NO_2 and SO_2 are expected to be low, concentrated within several hundred metres of Highway 5 as a result of emissions from vehicle traffic.

5.4.2.3 Black Pines to Hope Segment

Existing air quality conditions along the Black Pines to Hope Segment is considered for two main areas: in and around the City of Kamloops; and the City of Merritt.

Temperature inversions in the Thompson Valley can cause contaminants to accumulate in the Kamloops area, potentially resulting in poorer air quality than areas that do not have similar surrounding topography. This is evidenced by the PM concentrations in the Kamloops area, which are the highest amongst all BC areas along the proposed pipeline corridor. Nonetheless, existing air quality conditions in Kamloops are fair. Exceedances of the 24 hour BC provincial objective for PM_{10} were observed less than 1% of the time in 2008 and no exceedances of the 24 hour BC provincial objective for $PM_{2.5}$ were observed in 2011. Concentrations of CO, NO_2 and SO_2 remained below their respective air quality objectives in 2011.

There are no continuous monitoring stations near the City of Merritt. Existing air quality in the Merritt area is discussed qualitative based on a BC MOE air quality report describing a provincial monitoring study from 1990 to 2003. Observed PM concentrations in Merritt were relatively similar to those observed in Kamloops, with concentrations below the relevant objectives. BC MOE (2006) references high PM concentrations due to a beehive burner which has since been decommissioned. Higher PM levels in the Merritt area may be attributable to open burning, wood-burning appliances and vehicle traffic. Compared to Kamloops and other communities in the southern interior of BC, Merritt observed higher concentrations of CO and NO_2, and lower concentrations of SO_2. The higher concentrations of CO and NO_2 have been attributed to incomplete combustion emissions from motor vehicles.

There are no representative BTEX ambient monitoring data for the Black Pines to Hope Segment. BTEX concentrations along this segment are expected to be low.

5.4.2.4 Hope to Burnaby Segment

There are three main areas in which ambient monitoring data are available along the Hope to Burnaby Segment: in and around the District of Hope; the City of Chilliwack; and the City of Abbotsford. The highest CAC concentrations along the Hope to Burnaby Segment tend to be observed near the Abbotsford area, possibly due to a larger concentration of industrial sources in the area. Industrial sources in the Abbotsford area include gravel pits, chemical processing facilities and wood processing facilities. Overall, existing air quality conditions in the Hope, Chilliwack and Abbotsford areas with respect to CAC concentrations are good, with the 99th percentile of observed PM and NO_2 concentrations at approximately half the ambient air quality objectives or less, and the 99th percentile of observed CO and SO_2 concentrations less than 10% of the objectives.

BTEX concentrations along the Hope to Burnaby Segment are highest in the Chilliwack area. The highest BTEX concentration observed in the Chilliwack area during the 10 year period from 2002 to 2011 was 17.7 $\mu g/m^3$, compared to a maximum of 3.2 $\mu g/m^3$ in the Hope area and 13.7 $\mu g/m^3$ in the Abbotsford area (when excluding one outlier concentration in August 2006 at Hope and in July 2007 at Abbotsford). The higher BTEX concentrations observed in the Chilliwack area may be due to the influence of industrial sources such as wood and plastic product manufacturing facilities.

5.4.2.5 Burnaby to Westridge Segment

CAC monitoring data from eight Metro Vancouver stations in the Burnaby area were used to characterize existing air quality along the Burnaby to Westridge Segment: North Burnaby Capitol Hill; Burnaby North Eton; Burnaby Kensington Park; Port Moody; Coquitlam; North Vancouver Mahon Park; Second Narrows; and Burnaby South. The Burnaby Mountain Station was not considered since it is located at a higher elevation (360 m asl) compared to the rest of the area and data from this station may not be representative of the proposed pipeline corridor.

Ambient concentrations of PM and NO_2 were similar in magnitude amongst all stations in the Burnaby area. SO_2 concentrations in the Burnaby area were highest at the Burnaby North Eton Station, likely due to the influence of the nearby Chevron tank farm. CO concentrations were highest at the Port Moody and North Vancouver Mahon Park stations. The Port Moody Station may be influenced by the Burrard Generating Plant and the North Vancouver Mahon Park Station, located on higher terrain just north of the Vancouver Ship Yards and a private marina, may be influenced by marine emissions at the harbour. There were no exceedances of the Metro Vancouver air quality objectives in the Burnaby area in 2011.

One NAPS station measures BTEX concentrations in the Burnaby area. BTEX concentrations at the Burmount NAPS station over the last decade reached a maximum of 226.7 $\mu g/m^3$ and 115.2 $\mu g/m^3$ in June and July 2007, respectively. No explanation for these high readings could be found. BTEX data at Burmount reached up to 35.5 $\mu g/m^3$ when these high readings are not included.

5.4.3 Secondary Smog-Related Products

Smog refers to a mixture of gases and particles that often appear as haze in the air and is linked to a number of adverse effects on health and the environment. The two primary pollutants in smog are ground-level ozone and secondary PM, formed from atmospheric chemical reactions between precursors such as NO_x and VOCs.

Observed ozone concentrations for 2011 are summarized in Figure 5.4-10. For the most part, ozone concentrations along the proposed pipeline corridor have remained below relevant objectives. Ozone concentrations along the proposed pipeline corridor tend to be highest towards the east, in Alberta, and lowest towards the west, in the Burnaby area. High ozone concentrations in Alberta are attributable to large quantities of precursor NO_x and VOC emissions from petroleum refining and upgrading, and other heavy industries plus urban emissions in the Edmonton area, mining and oil and gas activity to the west of Edmonton towards Hinton and/or the topography of the region (*i.e.*, higher elevation). Within the Lower Fraser Valley, the eastern portion is prone to higher ozone concentrations due to the constricted nature of the valley and the tendency for precursor NO_x and VOC emissions to be transported eastward from Metro Vancouver and urban areas.

5.4.3.1 Edmonton to Hinton Segment

Short-term peak ozone concentrations along the Edmonton to Hinton Segment were similar amongst all four areas. However, average ozone concentrations were highest in the Hinton area and lowest in the Edmonton area. The Steeper Station, which was used to represent the Hinton area, may experience higher ozone concentrations due to its higher elevation and the potential for it to pick up natural background ozone from aloft. Lower ozone concentrations in the Edmonton area may be due to the presence of nitric oxide from vehicle traffic emissions in the urban area of Edmonton, which causes destruction of ozone.

5.4.3.2 Hargreaves to Darfield Segment

There is no representative ozone monitoring data available for the Hargreaves to Darfield Segment.

5.4.3.3 Black Pines to Hope Segment

Ozone concentrations measured in the Kamloops area in 2011 exceeded the 1 hour national maximum desirable objective 0.7% of the time and the 24 hour national maximum desirable objective 74% of the time. Based on the BC MOE air quality report (BC MOE 2006), ozone concentrations in the Merritt area based on the provincial monitoring study from 1990 to 2003 were similar to those observed in Kamloops.

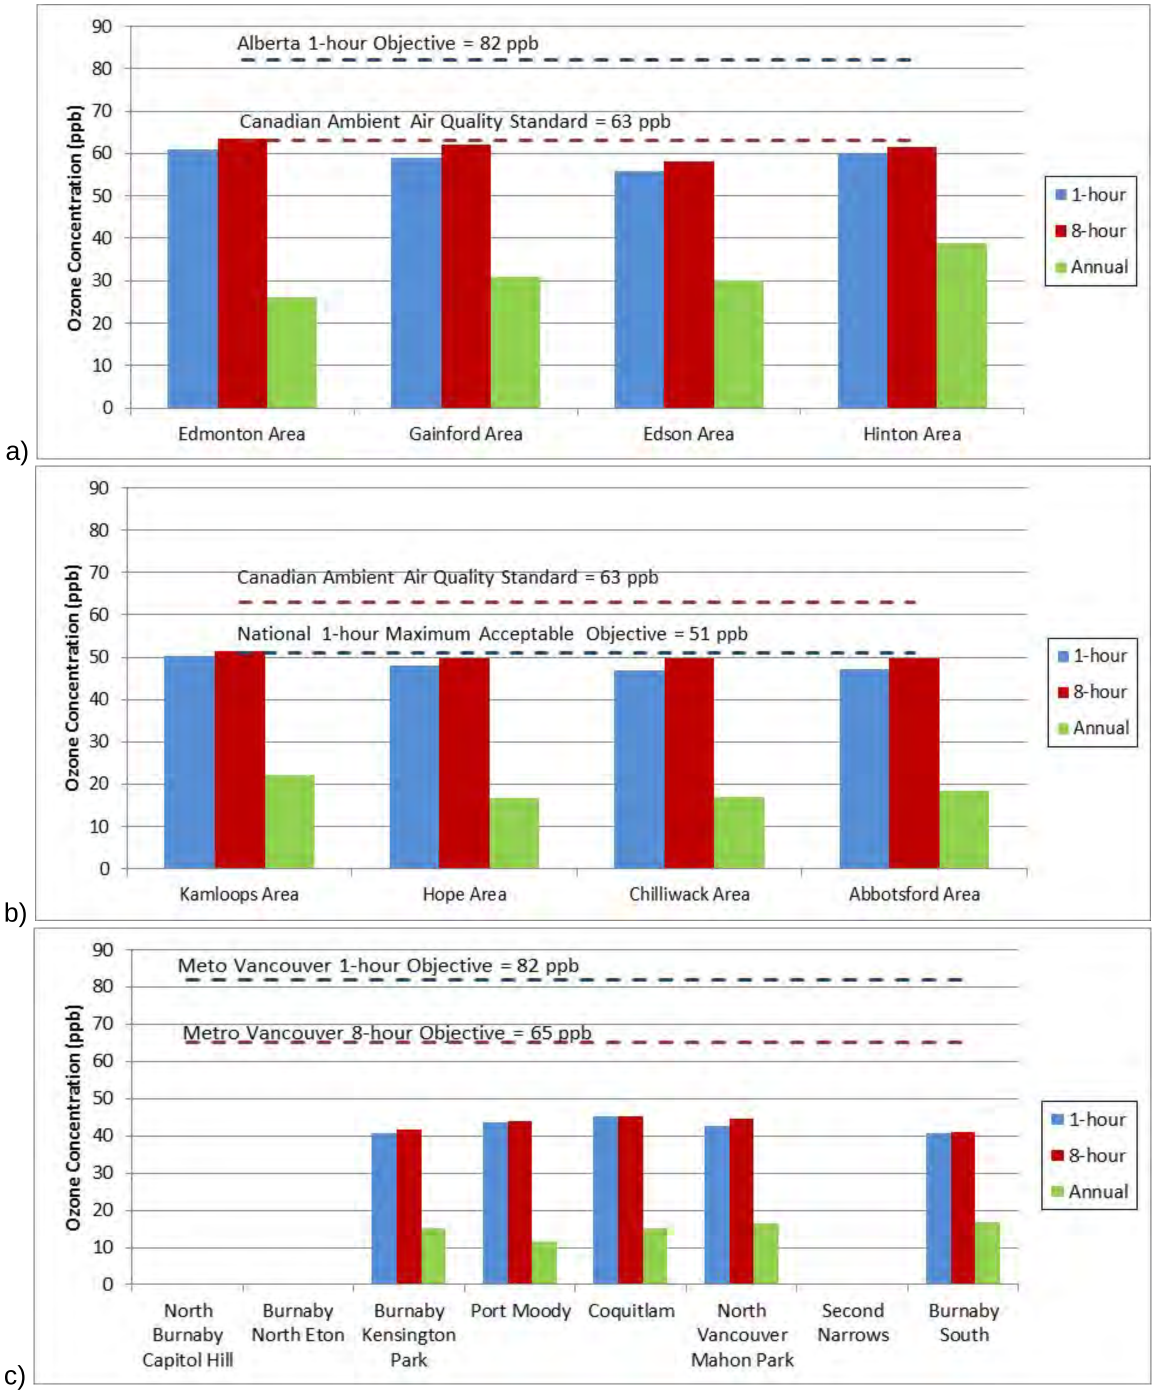
5.4.3.4 Hope to Burnaby Segment

Observed ozone concentrations in the Hope, Chilliwack and Abbotsford areas were similar to those for the Kamloops area discussed in Section 5.4.3.3.

5.4.3.5 Burnaby to Westridge Segment

The Burnaby Kensington Park, Port Moody, Coquitlam, North Vancouver Mahon Park, Second Narrows and Burnaby South stations monitor ozone. Ozone concentrations at all stations in the area are similar. Over the 10 year period from 2002 to 2011, there were occasional exceedances of the 1 hour and 8 hour Metro Vancouver objectives at the Port Moody and Coquitlam stations. There were also occasional exceedances of the 8 hour objective at the Burnaby Kensington Park and North Vancouver Mahon Park stations. No exceedances of the 1 hour or 8 hour Metro Vancouver objectives for ozone were observed at any of the stations in 2011.

Figure 5.4-10 Observed Ozone Concentrations in 2011 for (a) Alberta, (b) BC, Outside Metro Vancouver and (c) Metro Vancouver (in parts per billion [ppb])



Notes: The Canadian Ambient Air Quality Standard is based on the 4th highest annual 8 hour daily maximum value, averaged over 3 consecutive years, and will be effective in 2015, replacing the national ozone objectives.

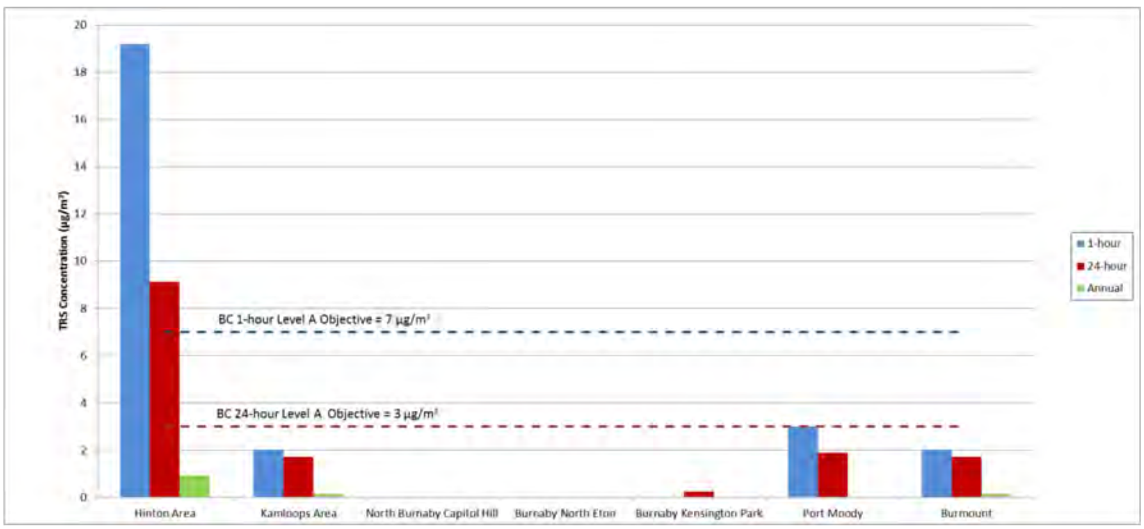
There is no annual ozone objective in Alberta, BC or Metro Vancouver.

5.4.4 Odorous Emissions

Reduced sulphur compounds are a complex family of substances defined by the presence of sulphur in a reduced state and are generally characterized by strong odours at relatively low concentrations. A common reduced sulphur compound is H_2S, a foul smelling gas resembling rotten eggs that is a by-product of anaerobic decomposition. H_2S can be further oxidized to form mercaptans which have strong odours resembling that of rotten garlic and are used as odorants to assist with the detection of natural gas. Individual reduced sulphur compounds are sometimes aggregated into what is known as TRS, expressed in terms of H_2S. These types of odours are often found in boiled eggs, raw sewage, swamps, brackish water, paper pulping mills, sour gas (*i.e.*, natural gas containing H_2S) and some condensates used to thin bitumen for shipping. Fugitive emissions from handling, shipping and storage of dilbit will be evaluated for their odour potential.

Only one CASA station in Edmonton measures H_2S concentrations. This is presented in Section 5.4.4.1. There is no monitoring data for mercaptans. Typically, monitoring data report TRS, which include H_2S and mercaptans and of which H_2S is the most prevalent. Observed TRS concentrations in 2011 are shown in Figure 5.4-11. TRS concentrations are highest in the Hinton area and those in the remaining areas were below the BC ambient objectives.

Figure 5.4-11 Observed TRS Concentrations in 2011 Along the Proposed Pipeline Corridor (in µg/m^3)



Note: There are no TRS objectives in Alberta or Metro Vancouver. BC objectives are shown to place observed concentrations in context. There is no annual TRS objective in BC.

5.4.4.1 Edmonton to Hinton Segment

The Edmonton East CASA station is the only station along the proposed pipeline corridor that records H_2S concentrations. In 2011, the maximum 1 hour and 24 hour concentrations remained below their respective Alberta ambient air quality objectives. The 99th percentile 1 hour concentration was approximately 30% of the objective.

Observed TRS concentrations along the proposed pipeline corridor were highest in the Hinton area. Since there are no Alberta or federal ambient air quality objectives for TRS, observed concentrations were compared to the BC objectives to place them in context. In 2011, 1 hour average TRS concentrations in the Hinton area were greater than 7 µg/m^3 (the 1 hour BC Level A objective) 5.9% of the time. For the 24 hour averaging period, concentrations were greater than 3 µg/m^3 (24 hour BC level A objective) 20% of the time. The high concentrations observed are likely attributable to the West Fraser Mills pulp and paper plant that reported 187 tonnes of TRS emissions to Environment Canada's National Pollutant Release Inventory (NPRI) in 2010 (Environment Canada 2013m).

5.4.4.2 Hargreaves to Darfield Segment

There is no representative TRS monitoring data available for the Hargreaves to Darfield Segment.

5.4.4.3 Black Pines to Hope Segment

TRS concentrations in the Kamloops area are available from June to December 2011. Overall, TRS concentrations were below detection limit most of the time. Exceedances of the 1 hour provincial objective were rare, having occurred less than 1% of the time from June to December 2011. TRS concentrations are not available for the Merritt area but are expected to be similar to Kamloops.

5.4.4.4 Hope to Burnaby Segment

There is no representative TRS monitoring data available for the Hope to Burnaby Segment.

5.4.4.5 Burnaby to Westridge Segment

The following Metro Vancouver monitoring stations in the Burnaby area monitor TRS: North Burnaby Capitol Hill; Burnaby North Eton; Burnaby Kensington Park; Port Moody; and Burmount. The Burmount Station is owned by KMC, but operated by Metro Vancouver and measures TRS near the Burnaby Terminal. TRS concentrations were highest at the Port Moody Station, followed by the Burmount and Burnaby North Eton stations. TRS concentrations at the Burnaby Kensington Park and North Burnaby Capitol Hill stations were low. No exceedances of the provincial or federal TRS objectives were observed at any of the stations in the 2002 to 2011 period.

5.5 Greenhouse Gas Emissions

This subsection discusses the existing conditions of the GHG emissions along the proposed pipeline corridor. The indicators selected for this element discussed below include common GHGs that are relevant to the Project (CO_2, CH_4, N_2O and SF_6) and the effect of the Project on climate change. The rationale for the selection of indicators is provided in Section 7.2.5. The potential Project-related effects and mitigation pertaining to the meteorological environment arising from construction and operation of the proposed pipeline are discussed in Section 7.2.5. Refer to the Air Quality and Greenhouse Gas Technical Report of Volume 5C for additional details on the existing conditions of the GHG emissions.

GHG emissions and the effects of the Project on climate change are global. With respect to the first indicator, common GHG, it is noted that global annual GHG emissions are aggregated from national inventories; moreover, in Canada this inventory is aggregated from provincial and territorial emission totals. Therefore, the estimated GHG emissions from the Project are set in the context of provincial, national and global emissions. In 2011, Canada had total GHG emissions of 702 Mt of carbon dioxide equivalent (CO_2e) as reported in the National Inventory Report 1990-2011 (Environment Canada 2013m). Alberta's contribution to national GHG emissions in 2011 was 72.7 Mt CO_2e, which is 10.4% of total Canadian emissions. Latest global GHG emission information available is for 2010 through the World Resources Institute (2013) CAIT tool. Including the effects of land use change and forestry, 2010 total global GHG emissions were approximately 47,183 Mt CO_2e.

An unknown percentage of the GHG emissions from fuel combustion in vehicles and aircraft for service, maintenance and aerial patrols are associated with the pipeline corridor. To ensure that all emissions are accounted for, aircraft emissions are attributed to the pipeline segments. This assumes that all jet fuel consumption was for the purpose of aerial patrols and that the aerial patrols primarily serve the pipeline segments. Only total GHG emissions from jet fuel combustion are known from previous years. The average GHG emissions over the last 3 years were pro-rated based on each pipeline segment's length. Since the pipeline is buried and sealed, no fugitive GHG emissions are expected to occur. In case of an accidental spill, small amounts of GHGs (*e.g.*, CH_4 and formation CO_2) associated with the product would be released, but would be classified as de-minimus (*i.e.*, intermittent, short-term or transient in nature) compared with GHG emissions from facility operations.

The main sources of direct GHG emissions as a result of pipeline operations are aerial patrols for maintenance purposes. Since pipelines are buried underground, no fugitive emissions are expected to happen under normal operations. Also, no indirect emissions are associated with the operation of the existing pipeline segments. Aerial patrols cause GHG emissions through the combustion of jet fuel. Associated GHG emissions were calculated for each pipeline segment averaged over years 2010 to 2012, and the results are summarized in Table 5.5-1.

TABLE 5.5-1

ANNUAL GHG EMISSIONS ASSOCIATED WITH THE EXISTING PIPELINE SEGMENTS (IN TONNES CO_2e)

Pipeline Segment	Length (km)	GHG Emissions
Edmonton to Hinton	318	97.6
Hargreaves to Darfield	268	84.7
Black Pines to Hope	227	69.6
Hope to Burnaby	135	41.4
Burnaby to Westridge	3.6	1.1
Total GHG Emissions		294.4

After global dispersion, the GHG emissions from any single industrial activity contribute very little to global emissions. Therefore, the current framework for environmental impact assessments is unlikely to trigger collective actions to reduce GHG emissions. Federal and provincial legislation has been put in place to address this issue. All facilities emitting more than 50,000 tonnes of GHGs are required to submit a report under Environment Canada's *Greenhouse Gas Emissions Reporting Program* (Environment Canada 2013m) pursuant to Section 46 of the *Canadian Environmental Protection Act*. Facilities in Alberta emitting more than 50,000 tonnes of GHGs are also required to submit reports under AESRD's *Specified Gas Reporting Regulation*. BC's *Reporting Regulation under the Greenhouse Gas Reduction (Cap and Trade) Act* sets out the requirements for reporting GHG emissions from BC facilities emitting 10,000 tonnes or more of GHGs. Facilities emitting 25,000 tonnes or more are required to have emissions reports verified by a third party. Based on the GHG emissions reported in Table 5.5-1, reporting would not be required from pipeline operations alone.

5.5.1 Climate Change

The second indicator is effects of the Project on climate change, defined as changes in long-term weather patterns caused by natural phenomena and human activities that alter the chemical composition of the atmosphere through the build-up of GHGs, which trap heat and reflect it back to the Earth's surface (Environment Canada 2013m). Annual temperatures in Canada have been at or above normal since 1993, with a warming trend of 1.5°C over the last 64 years (Environment Canada 2013m). It was demonstrated by Matthews *et al*. (2009) that global temperature increases are directly related to cumulative emissions of GHG. In its report, the National Research Council (NRC) (2010) estimated, based on the most current modeling results, approximately linear warming per cumulative emissions ranging from roughly 0.27°C to 0.68°C per 1,000,000 Mt CO_2e, or roughly 20 years of 2010 annual global GHG emissions. The NRC noted that other changes in the climate system and physical environment (*e.g.*, precipitation changes and decreases in crop yields) are likewise proportional to cumulative GHG emissions. On the basis of these expected changes per cumulative GHG emissions, the effect of the Project on climate change can be quantified (see Section 7.2.5).

5.6 Acoustic Environment

This subsection discusses the existing conditions of the acoustic environment. The indicators selected for this element discussed below include sound and vibration levels. The rationale for the selection of indicators is provided in Section 7.2.6. The potential Project-related effects and mitigation pertaining to the acoustic environment arising from construction and operation of the proposed pipeline are discussed in Section 7.2.6. Refer to the Terrestrial Noise and Vibration Technical Report of Volume 5C for additional details on the existing conditions of ambient sound and vibration levels.

This setting discusses the ambient sound level (ASL) within the Acoustic Environmental LSA, which is the ZOI potentially affected by sound generated during construction and operations, consisting of a 1.5 km band on both sides of the proposed pipeline corridor (*i.e.*, for a total width of 3.15 km). Vibration levels are discussed within the Acoustic Environment RSA, which is the area potentially affected by construction vibration, consisting of a 5 km band on both sides of the proposed pipeline corridor (*i.e.*, for a total width of 10.15 km). The spatial boundaries of the Acoustic Environment RSA are shown on Figures 5.4-1 to 5.4-4.

The ambient sound and vibration levels in the acoustic environment are a combination of both natural and/or man-made sources. Since each segment covers a vast area along the proposed pipeline corridor, the ambient levels at each potential receptor vary due to proximity to noise sources. A potential receptor has been defined in Section 7.2.6 as a residence or dwelling. Existing man-made sources can include, but are not limited to, transportation corridors, activities related to both energy and non-energy facilities, air craft flyovers and recreational trails.

5.6.1 All Pipeline Segments

Ambient conditions to be used in assessments are defined under the Alberta Energy Regulator (AER) *Directive 038: Noise Control Directive* (ERCB 2007) and BC Oil and Gas Commission (OGC) *Noise Control Best Practices Guideline* (BC OGC 2009) for each respective province. The normal operation of any buried pipeline does not create sound or vibration levels that are detectable or contributes to the ambient acoustical environment at surrounding receptors. The aspect of pipeline operation that may generate audible sound is when the pipeline is exposed at facilities and intermittent maintenance. Minor maintenance and inspections may be routinely completed, but have not been analyzed due to the infrequent nature of the activities. ASL along all segments of the proposed pipeline corridor (with the exception of major urban areas as noted in the subsections below) were assumed to follow the Category 1, least density for a populated area, for the ASL or base sound level (BSL), as per either AER *Directive 038: Noise Control Directive* (ERCB 2007) or BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009).

Details for each pipeline segment regarding receptors, dwelling density and roadway proximity are provided in the Terrestrial Noise and Vibration Technical Report of Volume 5C.

5.6.2 Edmonton to Hinton Segment

The ambient acoustic environment along the Edmonton to Hinton Segment of the proposed pipeline corridor is influenced in several areas by large facility operations and urbanized areas. The largest portion of this segment that is influenced by urbanization is the Edmonton area, which has large scale industrial operations, heavily travelled roadways, an airport and dense residential development. The existing sound levels are expected to be consistent with other dense urban developments with heavily travelled roads. The urban ASL based on AER *Directive 038: Noise Control Directive* (ERCB 2007) would range between 41-51 decibels (dBA) at night and 51-61 dBA during the day.

West of the Edmonton area, the proposed pipeline corridor loosely parallels Highways 16 and 16A. The ambient environment in close proximity to the highway will be elevated due to the presence of vehicle traffic. In general, if a heavily travelled roadway is within the Acoustic Environment LSA, then an elevated acoustic ambient environment may exist. AER *Directive 038: Noise Control Directive* (ERCB 2007) indicates that traffic affects ASLs at up to 500 m from the roadway, which is a consideration for assessing receptors within the Acoustic Environment LSA. The ASL at residences, based on AER *Directive 038: Noise Control Directive* (ERCB 2007), would range between 35-48 decibels (dBA) at night and 45-58 dBA during the day, depending on density of residential development and proximity to heavily travelled roads.

Several communities, including the City of Spruce Grove, the Hamlet of Entwistle and the towns of Stony Plain, Edson and Hinton, are located within the Acoustic Environment LSA. Due to the size of these communities, background sound levels are expected to reflect the degree of development based on density of residences and proximity to Highway 16/16A. The ASL at residences would range between 38-48 dBA at night and 48-58 dBA during the day, depending on density of residential development and proximity to heavily travelled roads.

The remainder of this pipeline segment is located in undeveloped, rural lands where natural sounds dominate the existing background. Some human activity may occur, but would not appreciably affect sound levels. For these areas, existing sound levels follow the rural ASL of 35 dBA at night and 45 dBA during the day as found in the AER *Directive 038: Noise Control Directive* (ERCB 2007).

Bylaws addressing noise or nuisance exist for communities where this segment of the proposed pipeline corridor is located within the respective community boundary. Bylaws exist for the cities of Edmonton and Spruce Grove, and the towns of Edson and Hinton. These noise bylaws state the hours of the day where it is acceptable to undertake activities (*e.g.*, construction) within the community and the City of Edmonton bylaw provides quantitative sound level limits. Generally, for most communities, activities are permitted from 7 AM to 10 PM, though timing is variable on weekends and holidays. No activities or sources of existing blast vibration were identified within the Acoustic Environment RSA for this segment.

5.6.3 Hargreaves to Darfield Segment

The main influences on the ambient acoustic environment along the Hargreaves to Darfield Segment of the proposed pipeline corridor are small communities, activities associated with forestry, small community airports and scattered commercial operations. This segment closely parallels Highway 5, with a deviation occurring between Blackpool Pump Station and the Village of Little Fort. The ambient environment in close proximity to Highway 5 will be elevated due to the presence of vehicle traffic. In general, if a heavily travelled roadway is within the Acoustic Environment LSA, then an elevated ambient acoustic environment may exist. The BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) indicates that traffic affects ASLs up to 500 m from the roadway, which is a consideration for assessing receptors within the Acoustic Environment LSA. The ASL at residences along the highways would range between 35-43 dBA at night and 45-53 dBA during the day.

Several communities, including the Village of Valemount, the communities of Blue River, Avola, Vavenby, the District of Clearwater and the Hamlet of Blackpool, are located within the Acoustic Environment LSA. Due to the size of these communities, background sound levels are expected to reflect the degree of development based on density of residences and proximity to Highway 5, as well as arterial roadways. The ASL at residences would range between 38-43 dBA at night and 48-53 dBA during the day.

The remainder of this segment is located in undeveloped, rural lands where natural sounds dominate the existing acoustic environment. Some human activity may occur, but would not appreciably affect sound levels. For these areas, existing sound levels follow the rural ASL of 35 dBA at night and 45 dBA during the day as found in the BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009).

This segment of the proposed pipeline corridor is located within the respective community boundary of the District of Clearwater. The District of Clearwater Bylaw No. 14 addresses nuisance noise and states the hours of the day where it is acceptable to undertake activities (*e.g.*, construction) within the community. Activities are permitted from 6 AM to 9 PM, though timing is variable on weekends and holidays. No activities or sources of existing blast vibration were identified within the Acoustic Environment RSA for this segment.

5.6.4 Black Pines to Hope Segment

The level of urbanization as well as forestry activities, airport flight routes and major industrial operations are the main influences of the ambient acoustic environment along the Black Pines to Hope segment of the proposed pipeline corridor. This segment follows several key transportation routes. The proposed pipeline corridor closely follows Westsyde Road to the north end of Kamloops (Westsyde), then follows trails to Kamloops and finally meanders and parallels Highways 5 and 5A to the District of Hope. The ambient environment in close proximity to the highway will be elevated due to the presence of vehicle traffic. In general, if a heavily travelled roadway is within the Acoustic Environment LSA, then an elevated acoustic ambient environment may exist. The BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) indicates that traffic affects ASLs at up to 500 m from the roadway, which is a consideration for assessing receptors within the Acoustic Environment LSA. The ASL at residences along the highways would range between 35-43 dBA at night and 45-53 dBA during the day.

Several communities, including the Hamlet of Black Pines, the cities of Kamloops and Merritt, and the District of Hope, are located within the Acoustic Environment LSA. Due to the size of these communities, existing sound levels are expected to reflect the degree of development based on density of residences and proximity to major highways and roadways. The ASL at residences would range between 38-43 dBA at night and 48-53 dBA during the day.

The remainder of this pipeline segment is located in undeveloped, rural lands where natural sounds dominate existing background. Some human activity may occur, but would not appreciably affect sound levels. For these areas, existing sound levels follow the rural ASL of 35 dBA at night and 45 dBA during the day as found in the BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009).

Bylaws addressing noise or nuisance exist for communities where this segment of the proposed pipeline corridor is located within the respective community boundary. Bylaws exist for the cities of Kamloops and Merritt, and the District of Hope. The noise bylaws address nuisance noise and state the hours of the day where it is acceptable to undertake activities (*e.g.*, construction) within the community. Generally, for most communities, activities are permitted from 7 AM to 10 PM, though timing is variable on weekends and holidays. No current activities or sources of existing blast vibration were identified within the Acoustic Environment RSA for this segment. The Ajax-Afton Mine near the City of Kamloops did include blasting activity, but stopped operations in 1997.

5.6.5 Hope to Burnaby Segment

The level of urbanization along the Hope to Burnaby segment changes from rural to areas with sparse housing to fully developed areas such as the cities of Surrey and Burnaby. The major sources contributing to the ambient acoustic environment are small industrial and commercial activities, aggregate operations and agricultural activities. The proposed pipeline corridor varies in distance from highways and communities.

The ambient environment for portions in close proximity to the highway will be elevated due to the presence of vehicle traffic. In general, if a heavily travelled roadway is located within the Acoustic Environment LSA, then an elevated acoustic ambient environment may exist. The BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) indicates that traffic affects ASLs up to 500 m from the roadway, which is a consideration for assessing receptors within the Acoustic Environment LSA. The urban ASLs based on the BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) for the cities of Surrey and Burnaby would range between 41-51 dBA at night and 51-61 dBA during the day.

Several communities, including the District of Hope, the cities of Chilliwack and Abbotsford, the Village of Clayburn, the Township of Langley and the cities of Surrey and Burnaby, are located within the Acoustic Environment LSA. Due to the size of these communities, background sound levels are expected to reflect the degree of development based on density of residences and proximity to major highways and roadways. The ASL at residences would range between 38-43 dBA at night and 48-53 dBA during the day.

Bylaws addressing noise or nuisance exist for communities where this segment of the proposed pipeline corridor is located within the respective community boundary. Bylaws exist for the cities of Chilliwack, Abbotsford, Surrey and Burnaby, and the Township of Langley. The noise bylaws address nuisance noise and state the hours of the day where it is acceptable to undertake activities (*e.g.*, construction) within the community. The cities of Chilliwack and Burnaby, and the District of Langley bylaws also provide some quantitative noise limits for residential areas. Generally, for most communities, activities are permitted from 7 AM to 10 PM, though timing is variable on weekends and holidays. No activities or sources of existing blast vibration were identified within the Acoustic Environment RSA for this segment.

5.6.6 Burnaby to Westridge Segment

There is a high level of urbanization along the Burnaby to Westridge Segment, as it is on the outskirts of the City of Burnaby. The major sources contributing to the ambient acoustic environment are due to human activities which include a large-scale industrial operation, activities along the waterway and vehicle roadways. The existing sound levels are expected to be consistent with other urban developments with heavily travelled roads. The urban ASL based on the BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) would range between 41-51 dBA at night and 51-61 dBA during the day.

The only applicable noise bylaw for this segment of the proposed pipeline corridor is the District of Burnaby's Bylaw No. 7332 (Corporation of the District of Burnaby 1979). This bylaw has a qualitative clause that no sound may disturb the peace and quiet in the area, stating that no sound, be it continuous or non-continuous, exceed the sound levels stated in the bylaw, in addition to providing qualitative and quantitative sound level limits for construction. Generally, construction activities are permitted from 7 AM to 10 PM on weekends and from 9 AM to 10 PM on weekends and holidays.

No activities or sources of existing blast vibration were identified within the Acoustic Environment RSA for this segment.

5.7 Fish and Fish Habitat

This subsection presents a summary of the findings related to fish and fish habitat in watercourses, non-classified drainages (NCDs) and fish-bearing wetlands crossed by the proposed pipeline corridor. The indicators selected for this element include riparian habitat, instream habitat, and fish mortality and injury. These three indicators apply in both Alberta and BC. A total of 11 indicator species (6 in Alberta and 5 in BC) were also selected. The rationale for the selection of indicators is provided in Section 7.2.7. Habitat potential for spawning, rearing, wintering and migration was rated at watercourse crossings identified along the proposed pipeline corridor and is documented in the Fish-Bearing Atlases (see Appendix C of the Fisheries [Alberta] Technical Report and Appendix B of the Fisheries [British Columbia] Technical Report of Volume 5C). The potential Project-related effects and mitigation pertaining to fish and fish habitat are discussed in Section 7.2.7.

This setting discusses the fish and fish habitat in the Fish and Fish Habitat LSA and the Aquatics RSA. The Fish and Fish Habitat LSA consists of the area extending 100 m above the centre of the proposed pipeline corridor to a minimum of 300 m downstream from the centre of the proposed pipeline corridor at defined watercourses and includes the area of riparian vegetation to a width of 30 m back from each bank edge the width of the construction right-of-way. The Aquatics RSA includes all watersheds directly affected by the Project. The spatial boundaries of the Aquatics RSA are shown on Figures 5.3-1 and 5.3-2.

All Aboriginal communities potentially affected by the Project were invited to participate in the fisheries field surveys conducted for the Project to allow for the collection of TEK. During the 2012 and 2013 fisheries field surveys, traditional methods of resource procurement were discussed, as well as modern methods currently employed. Seasonality of resource harvesting was also shared by the Aboriginal participants. At each investigating site, discussions were held with participants about the seasonality of fish and aquatic habitat and any changes to fisheries and aquatic resources over time. Potential mitigation measures to reduce any Project-related effects on a resource were also discussed during the fisheries field surveys. ATK includes, but is not limited to, the collection of TEK during field survey participation for the Project and TLU study information from potentially affected Aboriginal communities. Prior to TEK field data collection, preliminary background ATK data was compiled through sources such as open houses, community gatherings, public record of past projects and published reports.

5.7.1 Indicator Species

Indicator species were selected for each province as described in Section 7.2.7 based on initial feedback from regulatory authorities, Aboriginal communities, stakeholders and the professional judgment of the assessment team.

It was determined that each province traversed by the proposed pipeline corridor (*i.e.*, Alberta and BC) should have a unique set of fish species indicators due to several factors, including regional differences in fish community compositions, species abundance and the recreational, commercial or traditional use of fish. Indicator species in Alberta and BC included sportfish species of recreational, commercial and/or Aboriginal value that could potentially be encountered in watercourses crossed by the proposed pipeline corridor.

5.7.1.1 Alberta Indicator Species

Six indicator species (Arctic grayling, Athabasca rainbow trout, bull trout, burbot, northern pike and walleye) were selected for Alberta based on their distribution throughout the Aquatics RSA (see Fisheries [Alberta] Technical Report of Volume 5C), including 23 watercourses, NCDs or wetlands crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Table 5.7-6). The selection of indicator species in Alberta also considered interactions with stakeholders and species with management (*e.g.*, conservation) concerns. Of the six indicator species, five (*i.e.*, Arctic Grayling, Athabasca rainbow trout, burbot, northern pike and walleye) are neither *Species at Risk Act* [*SARA*]-listed or COSEWIC listed.

Fish play a large role in the subsistence lifestyle of many Aboriginal individuals and communities along the proposed pipeline corridor. According to Aboriginal communities, traditional fishing activities occur in waterbodies and watercourses crossed by the proposed pipeline corridor, and the species caught change seasonally. Species caught in the region include mountain trout (trout species), whitefish (mountain whitefish), jackfish (northern pike), rainbow trout, perch and pickerel (walleye) (Montana First Nation 2011, Neufeld 2012).

The use of lake sturgeon as an indicator species was suggested at the Edmonton ESA Workshop. Lake sturgeon is Endangered under the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) (2013a) and is considered Threatened under the Alberta *Wildlife Act* and *Wildlife Regulation*. Historical data and the results of the field program indicate that lake sturgeon is only found in one watercourse (*i.e.*, North Saskatchewan River) crossed by the proposed pipeline corridor (see Sections 4.4.1 and 5.0 of the Fisheries [Alberta] Technical Report of Volume 5C). Since lake sturgeon have a limited distribution in watercourses crossed by the proposed pipeline corridor, it was determined that this species would not be useful as an indicator since potential effects to lake sturgeon and their habitat would not be representative of potential effects to all fish and fish habitat in Alberta (see Section 7.2.7 for additional information about selection of indicator species).

Arctic grayling, Athabasca rainbow trout, bull trout, burbot, northern pike and walleye are found in watercourses crossed by the proposed pipeline corridor and elsewhere within the Aquatics RSA, according to historical data, literature review and/or field surveys. Table 5.7-1 shows the current distribution of the Alberta indicator species in the watersheds crossed by the Edmonton to Hinton Segment.

A brief description of the Alberta indicator species and their habitat requirements is presented in Sections 5.7.7 to 5.7.12. Additional information (*e.g.*, water quality requirements for each species) can be found in Section 4.3 of the Fisheries (Alberta) Technical Report of Volume 5C.

TABLE 5.7-1

CURRENT DISTRIBUTION OF ALBERTA INDICATOR SPECIES IN THE EDMONTON TO HINTON SEGMENT

5.7.1.2 British Columbia Indicator Species

Five indicator species (bull trout/Dolly Varden, Chinook salmon, coho salmon, cutthroat trout and rainbow trout/steelhead) were selected for BC based on their historical distribution throughout the Aquatics RSA, including 172 watercourses, NCDs and wetlands crossed by the proposed pipeline corridor (Tables 5.7-9, 5.7-13 and 5.7-17). The selection of indicator species in BC also considered interactions with stakeholders and species with management (*e.g.*, conservation) concerns. Of the five indicator species, two (*i.e.*, Chinook salmon and rainbow trout/steelhead) are neither *SARA* or COSEWIC listed.

There are four federally-listed (*i.e.*, *SARA*-listed) species (white sturgeon, green sturgeon, Nooksack dace and Salish sucker) in the Aquatics RSA that have not been used as indicator species because they are not well-represented (*i.e.*, distributed) in watercourses crossed by the proposed pipeline corridor and, therefore, potential effects to these species and their habitat are not representative of potential effects to fish and fish habitat as a whole.

The use of Nooksack dace as an indicator was considered after a suggestion by the FVRD. Nooksack dace is Endangered under COSEWIC (2013a) and *SARA* (Environment Canada 2013o) and has a very limited distribution in BC. Historical data and the results of the field program (see Section 4.4.4 of the Fisheries [British Columbia] Technical Report of Volume 5C) indicate that Nooksack dace are only found in two watercourse(s) (*i.e.*, Salmon River and Stoney Creek) crossed by the proposed pipeline corridor. Since Nooksack dace has a limited distribution in watercourses crossed by the proposed pipeline corridor, it was determined that this species would not be useful as an indicator since potential effects to Nooksack dace and their habitat would not be representative of potential effects to all fish and fish habitat in BC (see Section 7.2.7 for additional information about selection of indicator species).

Table 5.7-2 shows the current distribution of the BC indicator species in the watersheds crossed by the proposed pipeline corridor segments in BC.

A brief description of the indicator species and their habitat requirements is presented in Sections 5.7.13 to 5.7.17. Additional information (*e.g.*, water quality requirements for each species) can be found in the Fisheries (British Columbia) Technical Report of Volume 5C.

5.7.2 General Information – Edmonton to Hinton Segment

The proposed pipeline corridor along the Edmonton to Hinton Segment from RK 0.0 to RK 339.4 is located in both the North Saskatchewan and Athabasca river basins. There are 202 proposed waterbody crossings in this segment, of which 88 are crossings of watercourses (*i.e.*, having defined beds and banks). Of the 88 proposed watercourse crossings, 25 are located in the North Saskatchewan River Basin and 63 are located in the Athabasca River Basin.

The North Saskatchewan River originates from the Columbia Icefields in Banff National Park in western Alberta and flows for approximately 1,400 km to its confluence with the South Saskatchewan River in central Saskatchewan. The North Saskatchewan River generally flows northeast across Alberta, passing through the City of Edmonton before it crosses the provincial border into Saskatchewan.

The Athabasca River generally flows northeast from its mountain headwaters in Jasper National Park, in west central Alberta. It flows across the province and drains into Lake Athabasca, north of the City of Fort McMurray in northeast Alberta.

Many of the watercourses along the proposed Edmonton to Hinton Segment move slowly and TEK participants attribute this to beavers building dams that partially block the flow of water. Beaver dams have also influenced fish and their habitat, since these dams lower the water levels downstream.

The following subsections describe the watersheds, areas of special interest, hydrometric data, fish-bearing watercourses, riparian habitat and field results along the Edmonton to Hinton Segment.

5.7.2.1 Watersheds

Within the Alberta portion of the Project (*i.e.*, the Edmonton to Hinton Segment), the proposed pipeline corridor traverses eight watersheds. Watersheds were identified from the Environment Canada four-character sub-basins data (Prairie Farm Rehabilitation Administration - Agriculture and Agri-Food Canada 2008) and were assigned names based on the major watercourse within each watershed. The Lower, Middle and Upper North Saskatchewan River watersheds and the Sturgeon River Watershed comprise the area from the City of Edmonton to the Hamlet of Evansburg and drain into the North Saskatchewan River. The Pembina River, Upper and Lower McLeod River and the Athabasca River watersheds comprise the area from the Hamlet of Evansburg to the border of Jasper National Park and drain into the Athabasca River. The proposed pipeline corridor crosses several named watercourses within these watersheds, including the North Saskatchewan, Pembina, McLeod and Lobstick rivers. Table 5.7-3 provides the drainage areas and RK range(s) for each of the watersheds crossed by the Edmonton to Hinton Segment. Additional information about the watercourses crossed by the proposed pipeline corridor within each watershed is provided in the Fisheries (Alberta) Technical Report of Volume 5C.

TABLE 5.7-3

WATERSHEDS CROSSED BY THE PROPOSED PIPELINE CORRIDOR IN THE EDMONTON TO HINTON SEGMENT

Watershed	Approximate Drainage Area	RK Range(s)
Lower North Saskatchewan River	4,400 km²	RK 0 to RK 23.1
Middle North Saskatchewan River	3,100 km²	RK 23.1 to RK 51.5
Sturgeon River	3,300 km²	RK 51.5 to RK 75.2 RK 78.7 to RK 84.0 RK 117.5 to RK 131.0
Upper North Saskatchewan River	4,750 km²	RK 75.2 to RK 78.7 RK 84.0 to RK 117.5
Pembina River	6,250 km²	RK 131.0 to RK 191.5
Lower McLeod River	4,750 km²	RK 191.5 to RK 241.8
Upper McLeod River	4,900 km²	RK 241.8 to RK 278.0
Athabasca River	2,400 km²	RK 278.01 to RK 339.4

5.7.2.2 Areas of Special Interest

<u>Wabamun Lake Provincial Park</u>

Wabamun Lake Provincial Park is located approximately 60 km west of the City of Edmonton in the Upper North Saskatchewan River Watershed. Although the park is not crossed by the proposed pipeline corridor, the downstream LSA of two proposed crossings (two unnamed tributaries to Wabamun Lake [AB-36 and AB-39]) extends into the park. Wabamun Lake Provincial Park has the widest range of land and water users of any lake in Alberta including industrial, residential, recreational and agricultural uses

(Marshall Macklin Monaghan Western Limited 1985). A policy objective in the Lake Wabamun Management Plan (Marshall Macklin Monaghan Western Limited 1985) is to improve, develop and control the sport and commercial fishery at Lake Wabamun, since the importance of it as a valuable fisheries resource was recognized at the policy level. The erosion of bed and banks of Wabamun Lake was a topic of concern raised by participants at the Wabamun Lake Community Workshop. In Alberta, provincial parks are managed and designated under the *Provincial Parks Act.*

Environmentally Significant Areas

There are five Environmentally Significant Areas that have been identified as being traversed by the proposed pipeline corridor along this segment (Table 5.7-4). Environmentally Significant Areas are defined as those areas that are critical to the long-term maintenance of biological diversity, landscape features and natural processes at multiple spatial scales (Fiera Biological Consulting Ltd. 2009). Environmentally Significant Areas are categorised and defined based on seven different criteria: areas that contain elements of conservation concern; areas that contain rare or unique landforms; areas that contain habitat for local species; areas that contain important wildlife habitat; riparian areas; large natural areas; and sites of recognized significance. However, ATPR states that Environmentally Significant Areas do not represent government policy and do not necessarily require legal protection. They are intended to be an information tool to help inform land use planning and policy at local, regional and provincial scales.

TABLE 5.7-4

CHARACTERISTICS OF ENVIRONMENTALLY SIGNIFICANT AREAS TRAVERSED BY THE PROPOSED PIPELINE CORRIDOR IN THE EDMONTON TO HINTON SEGMENT

Environmentally Significant Area No.	Significance Rating	Natural Region; Natural Subregion	River Basins	Area (km²)	Criterion 1: Contains Elements of Conservation Concern	Criterion 2: Contains Rare or Unique Landforms	Criterion 3: Contains Habitat for Local Species	Criterion 4: Contains Important Wildlife Habitat	Criterion 5: Contains Riparian Areas			Criterion 6: Contains Large Natural Areas	Criterion 7: Contains Sites of Recognized Significance	Fish Species of Conservation Concern	Municipalities
									Headwater Streams	Intact Riparian Areas	Areas Along the Six Major Rivers				
70	Provincial	Foothills; Lower Foothills	Athabasca River	15.8	√				√	√				N/A	Yellowhead County
99	Provincial	Foothills, Boreal and Rocky Mountain; Lower Foothills, Central Mixedwood and Montane	Athabasca River	712.7	√	√			√	√	√	√		Pygmy whitefish	Woodlands, Yellowhead and Lac Ste. Anne counties, Municipal District of Greenview No. 16, County of Barrhead No.11

Source: Fiera Biological Consulting 2009

Canadian Heritage Rivers System

The headwaters of the North Saskatchewan River (*i.e.*, in Banff National Park) were designated to the Canadian Heritage Rivers System in 1989 (Canadian Heritage Rivers System 2011b). The 48.7 km long segment of the North Saskatchewan River designated as a Canadian Heritage River is outside of the Aquatics RSA and is not crossed by the proposed pipeline corridor. The proposed crossing of the North Saskatchewan River is several hundred kilometres downstream of the designated section.

A 168 km long segment of the Athabasca River that lies entirely within Jasper National Park was designated to the Canadian Heritage Rivers System in 1989 (Canadian Heritage Rivers System 2011c). The portion of the Athabasca River designated as a Canadian Heritage River is within the Aquatics RSA. There are no proposed crossings of the Athabasca River; however, there are tributaries to the Athabasca River crossed by the proposed pipeline corridor.

5.7.2.3 Hydrometric Data

The Water Survey of Canada maintains year-round hydrometric stations on several of the watercourses crossed by the proposed pipeline corridor along the Edmonton to Hinton Segment. A summary of discharge rates can be found in Table 5.7-5. Additional information about each station and the monthly mean flows can be found in Section 5.3 of this volume and in Appendix B of the Fisheries (Alberta) Technical Report of Volume 5C.

Seasonal flow patterns are similar between hydrometric stations identified in Table 5.7-5, indicating that the annual high flow events coincide with snowmelt. Flows are lowest during the winter months from October through March and discharge begins to increase during the spring, in April. Peak flows vary depending on the size and location of the waterbody. Lower elevation streams reach peak flows in early spring due to early spring snowmelt on the plains. Peak flows in the foothills correlate with spring snowmelt and are typically highest in mid-spring. Flow for mountain-fed streams correlates with delayed snowmelt in the mountains and is highest in early summer. Water flows in the North Saskatchewan River are regulated by two large hydroelectric dams. The Bighorn Dam is located on the North Saskatchewan River at Abraham Lake in the foothills of the Rocky Mountains. The Brazeau Dam is located on the Brazeau Reservoir near the Brazeau River's confluence with the North Saskatchewan River. These dams increase winter flows and decrease summer flows (Partners for the Saskatchewan River Basin 2009). The North Saskatchewan River reaches peak flow in July, while the smaller rivers and creeks reach peak flow from April to June. Flows begin to decline in July and continue to decline until October, just prior to freeze-up.

TABLE 5.7-5

SUMMARY OF STREAMFLOWS FROM HYDROLOGICAL STATIONS NEAR THE PROPOSED PIPELINE CORRIDOR IN THE EDMONTON TO HINTON SEGMENT

Watercourse Name	Station Name, Station Number	Years Station Data Available	Approximate Location of Station Relative to the Nearest RK	Month and Mean Monthly Discharge (m^3/s) During Lowest Flow Period	Month and Mean Monthly Discharge (m^3/s) During Highest Flow Period
North Saskatchewan River	North Saskatchewan River at Edmonton 05DF001	1911 to 2010	20 km downstream of RK 33.5	February 68.7 m^3/s	July 483.0 m^3/s
Pembina River	Pembina River near Entwistle 07BB002	1914 to 1923 1954 to 2010	2 km downstream of RK 135.0	February 2.31 m^3/s	May 48.9 m^3/s
McLeod River	McLeod River near Rosevear 07AG007	1984 to 2011	24 km downstream of RK 223.9	February 6.29 m^3/s	June 96.4 m^3/s

5.7.2.4 Fish-Bearing Crossings

Based on historical data or where field studies were conducted for the Project (see Fisheries [Alberta] Technical Report of Volume 5C), 56 of the 185 proposed crossings assessed were identified as fish-bearing (refer to the Fisheries [Alberta] Technical Report of Volume 5C) along the Edmonton to Hinton Segment. The 56 fish-bearing water crossings include 49 watercourses, 3 NCDs and 4 fish-bearing wetlands. An additional 17 sites, not assessed during the fisheries field program, have been defaulted to fish-bearing status. Table 5.7-6 provides a list of fish-bearing water crossings, their location along the proposed pipeline corridor, watershed, sensitivity rating, restricted activity periods (RAPs), recommended least risk biological windows, and the presence of indicator species. Additional information about these crossings, including known fish species presence, recommended crossing methods, water quality parameters, watercourse characteristics, and fish habitat ratings is provided in the Fisheries (Alberta) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing Atlas (Appendix C). Fish-bearing wetlands and drainages lack defined beds and banks and, therefore, do not fall under the Code of Practice in Alberta and have no classification or instream RAP. However, if sportfish are present, species-specific RAPs may be applicable, at the direction of the Qualified Aquatic Environment Specialist (QAES). Aboriginal participants reported that fly-fishing is the most common form of fishing along the Pembina River, but more traditional methods, such as net fishing are also used. Northern pike, suckers (sucker species), Arctic grayling and rainbow trout can be found in this river. Additional information is provided in the Fisheries (Alberta) Technical Report of Volume 5C.

The fish-bearing water crossings include one crossing of each of the North Saskatchewan, Pembina, Lobstick and McLeod rivers, 26 crossings of named creeks (including two crossings of Bench Creek), 3 NCDs and 7 wetlands (Table 5.7-6).

Fish and fish habitat sensitivity ratings were established for each proposed crossing using the professional judgment of a QAES and are based on the fish species present at the time of the field assessment or previously documented within a given system, flow regime (*i.e.*, seasonal or perennial) or the habitat type available for each life history stage (*e.g.*, spawning) of the key fish species present. This closely follows criteria defined by Fisheries and Oceans Canada (DFO) (Canadian Association of Petroleum Producers [CAPP] *et al.* 2005). A sensitivity rating allows the use of a risk assessment approach to determine the overall risk to fishes and their habitat at a given watercourse crossing. Ratings for Sensitivity of Fish and Fish Habitat allow regulators and the proponent to determine the level of risk associated with pipeline construction activities and methods/designs for pipeline and vehicle crossings for each proposed watercourse crossing. The associated effects can be evaluated by DFO to define the Categories of Risk (*i.e.*, Significant, Negative Effects, High Risk, Medium Risk and Low Risk) once an appropriate construction method and construction timing have been selected for a particular watercourse. Where fish habitat has been ranked as sensitive, the level of risk to fish and fish habitat has been determined to be high. Additional information about the evaluation criteria and corresponding sensitivity rankings is provided in the Fisheries (Alberta) Technical Report of Volume 5C.

Notes:
1 Project watershed as described in detail in Section 5.7.3.1.
2 Methodology for determination of watercourse sensitivity is described in detail in the Fisheries (Alberta) Technical Report of Volume 5C.
3 Athabasca rainbow trout may be pure, possible, suspected or confirmed (Table 4.21 of the Fisheries [Alberta] Technical Report of Volume 5C).
* Indicates that an aquatic assessment was not conducted at the site during the fisheries field program. These sites have been defaulted to fish-bearing status with a fish and fish habitat sensitivity rating of high until field work has been conducted (see Section 9.0 for information on supplemental studies).

5.7.2.5 Riparian Habitat

Riparian habitat composition at watercourses crossed by the proposed pipeline corridor within the Edmonton to Hinton Segment varies from east to west. Within the Edmonton Transportation/Utility Corridor (TUC) (RK 0.0 to RK 33.5), riparian habitat is largely comprised of mixed coniferous and deciduous trees, although grasses and shrubs are also present at some proposed crossing sites. Crown closure ranges from 1-40% at watercourses. From the Edmonton TUC to approximately RK 220.0 (*i.e.*, near the proposed crossing of Wolf Creek), riparian habitat composition shifts from being dominated by coniferous and deciduous trees to predominantly grasses and shrubs. Grazing is a common land use practice in this portion of the proposed pipeline corridor, resulting in diminished riparian health and diversity. Crown closure in this portion of the proposed pipeline corridor generally ranges between 0-20%. As the proposed pipeline corridor extends into the Green Area (RK 247.9) to the western boundary of the Edmonton to Hinton Segment, riparian habitat shifts back to (in general) mature stands of deciduous and coniferous trees, with grasses and shrubs included in some instances. Crown closure ranges between

0-70% in this portion. The total area of riparian habitat within the Aquatics RSA in the Edmonton to Hinton Segment is approximately 193,182.1 ha.

5.7.2.6 Field Results

A total of 202 potential water crossings were identified in the proposed pipeline corridor along the Edmonton to Hinton Segment. During the fisheries field program, habitat use and potential were assessed at 185 locations. Limited access permission and limiting existing information at the remaining 17 locations prevented field assessments (see Section 9.3). Of the 185 crossings assessed during the fisheries field program, 39 were visited in 2 seasons. There were 3 crossings visited during the 2012 fall spawning survey, 16 were visited during the 2013 wintering habitat potential assessment, 138 were assessed during the spring 2013 fisheries program and 4 crossings were visited during the fall 2013 spawning assessment. Of the 185 potential watercourse crossings assessed during the fisheries field program of where suitable historic information exists, 56 were determined to be fish-bearing and 129 were determined to be nonfish-bearing. The 17 potential crossings not assessed during the fisheries field program are presumed to be fish-bearing and to have a fish and fish habitat sensitivity rating of high based on previously documented fish information or by default.

During the field surveys, traditional methods of resource procurement were discussed, as well as modern methods currently employed. Seasonality of resource harvesting was also important information shared by the Aboriginal participants. Geographical locations were identified, as were areas that are not used and the reasons why these are not used. Participants assisted in the identification of potential fish species within each watercourse crossed. At each investigation site, discussions were held with participants about the seasonality of fish, aquatic habitat, water quality and quantity, suitability for navigation and any changes to fisheries and water resources over time. Potential mitigation measures to reduce any Project-related effects on a resource were also discussed during the fisheries field surveys. Open discussions occurred regularly between participants and TEK facilitators regarding the resources present and available to Aboriginal communities. These discussions were important to help build relationships among the field crews. Aboriginal participants spoke about aspects of the environment that were important to them and the importance of the resource from a western science perspective was also discussed. The TEK collected during the fisheries field surveys has: added results that western science may not have gathered or considered; confirmed results that had been collected through the field surveys; and identified and confirmed issues of concern to be addressed. The TEK collected is also used to assist in the review of potential Project-related effects on fish and fish habitat.

<u>Fish and Fish Habitat Assessment</u>

Fish and fish habitat assessments (Fisheries [Alberta] Technical Report of Volume 5C) were conducted in order to document existing fish and fish habitat conditions at each proposed water crossing with fish and fish habitat. Information will be provided to DFO to assist with any case-specific reviews of water crossings they may need to conduct.

During the fisheries field program, 157 of the 185 crossings were determined to be sites of Low sensitivity for species of management concern (*i.e.*, sportfish and/or provincially or federally-listed fish species). This total includes all 129 crossings of nonfish-bearing habitat and 28 crossings of fish-bearing habitat. Sites with fish habitat of High sensitivity for species of management concern were confirmed at 28 of 56 proposed crossings of known fish-bearing habitat. These High sensitivity sites resulted where fish capture or observation included species of management concern and/or where the habitat potential for species of management concern of two or more fish life stages (*i.e.*, of rearing, spawning and wintering) were rated as Moderate-High or High. Refer to Section 5.2 of the Fisheries (Alberta) Technical Report of Volume 5C for further details.

Indicator Species

Information on indicator species captured or observed during the fisheries field program are discussed in Sections 5.7.7 to 5.7.12.

Species of Management Concern

Five of the 12 additional species of management concern (*i.e.*, in addition to indicator species) that occur frequently within the Edmonton to Hinton Segment were captured at watercourse crossings within the proposed pipeline corridor. These species include: brook trout; rainbow trout (introduced populations); mountain whitefish; mooneye; and spoonhead sculpin. Species of management concern that were not captured or observed at any of the proposed crossings within the studied watercourse crossings include brown trout; lake sturgeon; cutthroat trout; yellow perch; sauger; goldeye; and northern redbelly dace.

Brook trout were captured or observed at eight watercourses. One watercourse is within the Lower McLeod River Watershed, one watercourse is located within the Upper McLeod River Watershed and six watercourses are located within the Athabasca River Watershed. Rainbow trout (introduced populations) were captured or observed at four watercourses; one watercourse lies within the Lower McLeod River Watershed and the other three watercourses are located within the Athabasca River Watershed. Mountain whitefish were captured or observed at five watercourses. One watercourse is located within the Middle North Saskatchewan River Watershed, one watercourse is within the Pembina River Watershed, two watercourses lie within the Lower McLeod River Watershed and one watercourse is within the Upper McLeod River Watershed. Mooneye were captured or observed at one watercourse in the Middle North Saskatchewan River Watershed. Spoonhead sculpin were captured from one watercourse in the Pembina River Watershed and one watercourse in the Athabasca River Watershed.

Refer to Section 5.2.8 of the Fisheries (Alberta) Technical Report of Volume 5C for additional information on watercourses at which species of management concern were captured or observed.

Spawning Assessments

Spawning assessments were performed in September 2012 in the Pembina River (RK 135.0), Wolf Creek (RK 220.6) and McLeod River (RK 223.9) and in September 2013 at Maskuta, Hardisty, Sundance and Little Sundance creeks.

A total of 102 fish were observed in the Pembina River. Most were sucker species, although, mountain whitefish, walleye and trout species were also observed. No spawning activity was observed; however, fish were observed using the deep pool habitat, supporting the high habitat sensitivity rating assigned to the Pembina River. According to TEK participants, fish are abundant in watercourses in the fall and participants reported that the fish caught in the fall taste better than those caught at other times of the year.

Comparatively fewer fish were observed during the snorkel survey of Wolf Creek (RK 220.6) (n=68) which included mountain whitefish, Arctic grayling, brook trout, northern pike, trout species (unidentified) and sucker species (unidentified). One redd was identified and presumed to be that of a nearby brook trout. Spawning activity and diversity of species observed during the fall 2012 survey support the high habitat sensitivity rating assigned to Wolf Creek.

Results from the 2012 fall spawning survey supported the assertion that fish habitat near the proposed crossing of the McLeod River is of high sensitivity for species of management concern since 4,225 fish were observed. This total was comprised of Arctic grayling, mountain whitefish, northern pike, walleye, burbot, rainbow trout (introduced populations) and sucker species. Many of the mountain whitefish were estimated to be of adult size and presumed to be staging or in the process of spawning.

A total of 11 fish were observed at Maskuta Creek during the 2013 spawning survey. Of this, eight fish were confirmed to the species-level (*i.e.*, five rainbow trout and three brook trout). Two additional trout (unconfirmed species) and one sculpin (unconfirmed species) were also observed.

The 2013 spawning survey at Hardisty Creek observed 130 fish, including rainbow trout (n=53), brook trout (n=29). An additional 48 trout (unidentified) were also observed. No confirmed observations of mountain whitefish or bull trout resulted.

The survey at Sundance Creek observed 162 fish, including mountain (n=153), rainbow trout (n=2), burbot (n=2) and 5 sucker species. The rainbow trout occurring in Sundance Creek are “possible” pure strain Athabasca rainbow trout (Sterling pers. comm.).

No fish or redds were observed during the spawning assessment at Little Sundance Creek due to numerous woody debris piles and abundant instream vegetation, which limited the effectiveness of the snorkel survey. Although no fish were observed during the fall 2013 spawning assessment, limited visibility and abundant cover elements indicate that the absence of spawning activity should not be assumed.

2013 Potential Wintering Habitat Survey

A total of 16 proposed crossings were visited during the 2013 potential wintering habitat survey. Of these, seven were confirmed as having habitat of high sensitivity for species of management concern or rated higher (*i.e.*, as compared to ratings assigned during assessments conducted in the open water season). Winter habitat ratings for five watercourse crossings diminished due to limited water depth, flow and water quality parameters (Section 5.2.5 of the Fisheries [Alberta] Technical Report of Volume 5C).

5.7.3 General Information - Hargreaves to Darfield Segment

The proposed pipeline corridor along the Hargreaves to Darfield Segment from RK 489.6 to RK 769.0 traverses the Fraser River Basin for most of its length, with only a 20 km section (RK 527.9 to RK 547.7) in the Columbia River Basin. The Fraser and Columbia River basins have drainage areas of 232,300 km^2 and 102,800 km^2, respectively (Fisheries [British Columbia] Technical Report of Volume 5C). There are 349 proposed water crossings along the Hargreaves to Darfield Segment, of which 189 are crossings of watercourses (*i.e.*, having defined beds and banks), including the Fraser, Canoe, North Thompson and Clearwater rivers.

The Fraser River, the longest river in BC, originates in Mount Robson Provincial Park in BC, flowing northwest to Prince George before bending south to the Lower Mainland where it enters the Pacific Ocean after 1,370 km. The Fraser River Basin provides spawning and rearing habitat for six species of Pacific salmon (including steelhead trout) and is the largest salmon producing river in BC (DFO 2012). There are seven proposed watercourse crossings in the Fraser River Basin within this segment, including one proposed crossing of the Fraser River at RK 499.7.

The Columbia River originates in the Rocky Mountain Trench. It flows northwest through the Columbia Valley to Kinbasket Lake, after which it flows south, eventually crossing the border into the US before draining into the Pacific Ocean. The total length of the Columbia River is approximately 1,930 km, of which 668 km is in Canada (US Geological Survey 2013). The Columbia River is not crossed by the proposed corridor along this pipeline segment, although there are seven crossings of watercourses that drain into the Columbia River Basin, including one proposed crossing of the Canoe River upstream of Kinbasket Lake at RK 531.3.

The Canoe River originates in the Caribou Mountains and flows east for approximately 40 km to its confluence with Kinbasket Lake. This arm of Kinbasket Lake is referred to as Canoe Reach and was previously the lower reaches of the Canoe River. Canoe Reach was created when lower portions of the Canoe River were flooded during installation of the Mica Dam in 1973.

The headwaters to the North Thompson River originate in the Caribou Mountains at the foot of the Thompson Glacier, east of Wells Gray Provincial Park. The North Thompson River flows approximately 325 km, first east towards Highway 5 then south, to its confluence with the South Thompson River at Kamloops, marking the beginning of the Thompson River which shortly drains into Kamloops Lake. There are three proposed crossings of the North Thompson River (at RK 581.2, RK 619.9 and RK 651.6) along the Hargreaves to Darfield Segment. Other river crossings include three proposed crossings of the Albreda River (RK 552.1, RK 561.2 and RK 563.6) and one each of the Thunder (RK 600.2), Blue (RK 613.8), Mad (RK 683.4), Raft (RK 717.7) and Clearwater (RK 725.5) rivers, all of which are tributaries to the North Thompson River.

The Clearwater River is a direct tributary to the North Thompson River, flowing mainly south for 201 km from its headwaters to the confluence with the North Thompson River. The Clearwater River flows through Wells Gray and North Thompson River provincial parks for much of its length. There is one proposed crossing of the Clearwater River in the Hargreaves to Darfield Segment at RK 725.5.

Fishing remains an important traditional and commercial activity for Aboriginal communities residing in BC. The Barriere, Fraser, Raft, Blue, Albreda and North Thomson rivers, and Lemieux, Dunn, Moonbeam, and Finn creeks are currently fished by TEK participants.

The following subsections describe the watersheds, areas of special interest, hydrometric data, fish-bearing watercourses, riparian habitat and field results along the Hargreaves to Darfield Segment.

5.7.3.1 Watersheds

The proposed pipeline corridor traverses five watersheds in this segment, identified by the BC Freshwater Atlas Watershed Groups data file (BC MFLNRO 2008a). The Upper Fraser, Upper and Lower North Thompson and Clearwater river watersheds drain into the Fraser River Basin. The Canoe Reach Watershed is the only watershed crossed within the Columbia River Basin.

Table 5.7-7 provides the drainage areas and RK range(s) for each of the watersheds crossed by the proposed pipeline corridor in the Hargreaves to Darfield Segment. Additional information about the watercourses crossed by the proposed pipeline corridor within each watershed is provided in the Fisheries (British Columbia) Technical Report of Volume 5C.

TABLE 5.7-7

WATERSHEDS CROSSED BY THE PROPOSED PIPELINE CORRIDOR IN THE HARGREAVES TO DARFIELD SEGMENT

Watershed	Approximate Drainage Area	RK Range(s)
Upper Fraser River	6,759 km²	RK 489.6 to RK 527.9
Canoe Reach	3,168 km²	RK 527.9 to RK 547.7
Upper North Thompson River	5,388 km²	RK 547.7 to RK 722.9 RK 723.0 to RK 723.1 RK 724.0 to RK 724.5
Clearwater River	3,113 km²	RK 722.9 to RK 723.0 RK 723.1 to RK 724.0 RK 724.5 to RK 725.2 RK 725.2 to RK 725.3 RK 725.3 to RK 725.9
Lower North Thompson River	4,911 km²	RK 725.2 to RK 725.2 RK 725.3 to RK 725.3 RK 725.9 to RK 769.0

5.7.3.2 Areas of Special Interest

Finn Creek Provincial Park is traversed by the proposed pipeline corridor from RK 638.7 to RK 639.3 and there are two proposed crossings of watercourses in the park (BC-201 and BC-202). Participants of the Blue River Community Workshop commented that Finn Creek Provincial Park contains good quality salmon habitat. The proposed pipeline corridor also crosses one watercourse (BC-312) in the North Thompson River Provincial Park, which is traversed from RK 725.5 to RK 725.9.

The entire length of the Fraser River, from its origins in Mount Robson Provincial Park to its outflow into the Pacific Ocean at Vancouver, is designated as a Canadian Heritage River by the Canadian Heritage Rivers System as well as a BC Heritage River by the BC MOE (BC MOE 2011b, Canadian Heritage Rivers System 2011a). No other designated or nominated Canadian or BC Heritage Rivers are crossed by the proposed pipeline corridor in this segment (BC MOE 2011c, Canadian Heritage Rivers System 2011a).

There are no national parks, Fisheries Sensitive Watersheds or other areas of special interest traversed by this proposed pipeline segment (BC MOE 2013e).

5.7.3.3 Hydrometric Data

The Water Survey of Canada maintains several hydrometric stations on watercourses crossed by the proposed pipeline corridor in this segment (Table 5.7-8). In general, the annual high flow event occurs in spring/early summer (*i.e.*, May to July) and mean monthly flows are lowest in the winter (*i.e.*, February and March). Additional information about each station and the monthly mean flows can be found in Section 5.3.

TABLE 5.7-8

SUMMARY OF STREAMFLOWS FROM HYDROLOGICAL STATIONS NEAR THE PROPOSED PIPELINE CORRIDOR IN THE HARGREAVES TO DARFIELD SEGMENT

Watercourse Name	Station Name, Station Number	Years Station Data Available	Approximate Location of Station Relative to the Nearest RK	Month and Mean Monthly Discharge (m^3/s) During Lowest Flow Period	Month and Mean Monthly Discharge (m^3/s) During Highest Flow Period
Fraser River	Fraser River at Red Pass 08KA007	1955 to 2010	27 km upstream of RK 499.7	March 5.32 m^3/s	June 152 m^3/s
Clearwater River	Clearwater River Near Clearwater Station 08LA001	1914 to 1919 1921 to 1928 1950 to 2010	2 km upstream of RK 725.5	February 45.3 m^3/s	June 714 m^3/s
North Thompson River	North Thompson River at Birch Island 08LB047	1960 to 2010	65 km downstream of RK 651.7	February 28.1 m^3/s	June 444 m^3/s

Sources: Environment Canada 2013e-g

5.7.3.4 Fish-Bearing Crossings

Based on historical data and field studies conducted for the Project (see Fisheries [British Columbia] Technical Report of Volume 5C), 84 of the proposed water crossings were identified as fish-bearing. Table 5.7-9 provides a list of fish-bearing water crossings, their location along the proposed pipeline corridor, watershed, sensitivity rating, instream work windows, least risk biological windows and the presence of indicator species. Additional information about these crossings, including known fish species presence, recommended crossing methods, water quality parameters, watercourse characteristics, and fish habitat ratings is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing Atlas (Appendix B).

The fish-bearing watercourse crossings include at least one proposed crossing of each of the Fraser, Canoe, Albreda, North Thompson, Mad, Raft, Clearwater, Thunder and Blue rivers (Table 5.7-9). Participants of the Blue River and Kamloops Community Workshops agreed that important fish habitat is found in at least two of the named rivers (*i.e.*, Blue River, Thompson River).

TEK participants identified several types of salmon during field surveys along the proposed Hargreaves to Darfield Segment including: Chinook; dog (*i.e.*, chum); coho; and sockeye.

Sensitivity ratings were established using the professional judgment of a Qualified Environmental Professional (QEP) and are based on the fish species present at the time of the field assessment or previously documented within a given system, flow regime (*i.e.*, seasonal or perennial) or the habitat type available for each life history stage (*e.g.*, spawning) of the key fish species present. This closely follows criteria defined by DFO (CAPP *et al.* 2005). A sensitivity rating allows the use of a risk assessment approach to determine the overall risk to fishes and their habitat at a given watercourse crossing. Additional details about the fish and fish habitat sensitivity ratings are provided in Section 5.7.2.4 and the Fisheries (British Columbia) Technical Report of Volume 5C.

TABLE 5.7-9

FISH-BEARING WATER CROSSINGS ALONG THE PROPOSED PIPELINE CORRIDOR OF THE HARGREAVES TO DARFIELD SEGMENT

Site No.	RK	Name	Watershed[1]	Sensitivity Rating[2]	Historical Indicator Species Present (Captured/Observed)[3]	Instream Work Window [BC MOE and DFO] (Least Risk Biological Window)[4]

Notes:
1 Project watershed as described in detail in Section 5.7.4.1.
2 Methodology for determination of watercourse sensitivity is described in detail in the Fisheries (British Columbia) Technical Report of Volume 5C.
3 Blended species indicator (*i.e.*, bull trout/Dolly Varden, rainbow trout/steelhead) presence indicates that at least one species was found at the watercourse.
4 Watercourses requiring ongoing studies are identified in Appendix F of the Fisheries (British Columbia) Technical Report of Volume 5C.
* Indicates unidentified species because it was only observed, therefore; species level could not be positively identified.

5.7.3.5 Riparian Habitat

Riparian habitat composition at watercourses crossed by the proposed pipeline corridor within the Hargreaves to Darfield Segment (RK 489.6 to RK 769.0) varies. Within the Hargreaves to Darfield segment the main biogeoclimatic zone crossed is the Interior Cedar-Hemlock (ICH) Zone. Riparian habitat within this zone is mainly comprised of mixed coniferous trees: ponderosa pine; Douglas-fir; western larch; lodgepole pine; and western white pine. Devil's club and large ferns are also common within the riparian zone.

5.7.3.6 Field Results

Fish and fish habitat assessments (Fisheries [British Columbia] Technical Report of Volume 5C) were conducted in order to document existing fish and fish habitat conditions at proposed watercourse crossings with fish and fish habitat. A total of 333 potential watercourse crossings were assessed within the Hargreaves to Darfield Segment. Three sites (*i.e.*, Baer, Marathon and Terry Fox creeks [BC-3, BC-5 and BC-8, respectively]) have been assigned a stream classification based on adequate historical information. Overall, 84 watercourse crossings are considered to be fish-bearing and 252 are considered to be nonfish-bearing based on sites assessed in the field and historical information. Sixteen potential watercourse crossings require ongoing studies to confirm stream classification (see Appendix F of the Fisheries [British Columbia] Technical Report of Volume 5C). Table 5.7-10 summarizes the stream classifications for all fish-bearing and nonfish-bearing drainages crossed by the proposed pipeline corridor along the Hargreaves to Darfield Segment.

TABLE 5.7-10

STREAM CLASSIFICATIONS OF POTENTIAL CROSSINGS INVESTIGATED ALONG THE HARGREAVES TO DARFIELD SEGMENT

Classification[1]	Total Number
Fish-bearing	
S1A	4
S1B	9
S2	33
S3	21
S4	9
NCD-W/Wetlands	8
Nonfish-bearing	
S5	14
S6	99
NCDs	62
NVCs	62
NCD-W/Wetlands	15

Note: 1 Classification refers to BC Stream Classification System (BC Ministry of Forests [BC MOF] 1995).

Of the 84 proposed fish-bearing crossings in the Hargreaves to Darfield Segment, 68 were rated as High sensitivity while the 16 fish-bearing crossings were rated as Low sensitivity (Table 5.7-10 of this volume and Section 5.2 of the Fisheries [British Columbia] Technical Report of Volume 5C).

Indicator Species

Information on indicator species captured or observed during the fisheries field program is discussed in Sections 5.7.13 to 5.7.17.

Species of Management Concern

No *SARA*-listed species were captured or observed along the Hargreaves to Darfield Segment during the 2012/2013 fisheries field program. Bull trout, which are Blue-listed provincially (BC Conservation Data Centre [CDC] 2013a) were captured during the 2012/2013 fisheries fish program and these results are discussed in Section 5.7.13. Coho salmon, which is listed as Endangered under COSEWIC (2013a), was also captured and is discussed in Section 5.7.15. Additional information about species of management concern captured or observed during the 2012/2013 fisheries field program is provided in the Fisheries [British Columbia] Technical Report of Volume 5C.

5.7.4 General Information - Black Pines to Hope Segment

The Black Pines to Hope Segment, from RK 811.9 to RK 1043.7, lies entirely within the Fraser River Basin. There are 318 proposed crossings in this segment, of which 111 are crossings of watercourses (*i.e.*, having defined beds and banks), including the Thompson, Nicola, Coquihalla and Coldwater rivers. There are no proposed crossings of the South Thompson River.

The Thompson River drains from Kamloops Lake near the Town of Savona and flows southwest for approximately 120 km to its confluence with the Fraser River. The Thompson River is the largest tributary to the Fraser River and supports five species of Pacific salmon (DFO 2011). TEK participants identified the North Thompson River as a major salmon migration route. The salmon run in this river from August through September or October. There is one proposed crossing of the Thompson River at RK 846.8 in the Black Pines to Hope Segment.

The Nicola River is a major tributary to the Thompson River, which drains west from the Thompson Plateau and feeds both Douglas and Nicola lakes. From the outlet to Nicola Lake, the Nicola River meanders northwest for approximately 85 km to its confluence with the Thompson River near the Town of Spences Bridge. Both trout and salmon are present in the Nicola River according to TEK participants. There is one proposed crossing of the Nicola River at RK 928.0 in the Black Pines to Hope Segment.

The Coldwater River originates in the Cascade Mountains near the Coquihalla Summit Recreation Area. The Coldwater River flows for approximately 95 km, mostly paralleling Highway 5, before draining into the Nicola River near the City of Merritt. There are four proposed crossings of the Coldwater River (at RK 957.9, RK 970.3, RK 980.0 and RK 990.0) along the Black Pines to Hope Segment.

The Coquihalla River originates in the Coquihalla Lakes within the Coquihalla Summit Recreation Area. The Coquihalla River flows through the Cascade Mountains, following Highway 5 and Old Coquihalla Road for approximately 56 km to its confluence with the Fraser River at the District of Hope. The Coquihalla is a major tributary to the lower Fraser River and is known to support all six species of Pacific salmon. TEK participants noted that fish are healthier in the smaller fresh water watercourse in the region since the water quality in the Coquihalla is poor. There are five proposed crossings of the Coquihalla River (at RK 1021.8, RK 1026.5, RK 1028.6, RK 1032.6 and RK 1043.2) along the Black Pines to Hope Segment.

The following subsections describe the watersheds, areas of special interest, hydrometric data, fish-bearing watercourses, riparian habitat and field results along the Black Pines to Hope Segment.

5.7.4.1 Watersheds

The Black Pines to Hope Segment lies entirely within the Fraser River Basin and traverses several watersheds. The proposed pipeline corridor crosses the Lower North Thompson, Thompson, South Thompson and Lower Nicola river watersheds as well as the Fraser Canyon Watershed (BC MFLNRO 2008a).

Table 5.7-11 provides the drainage areas and RK range(s) for each of the watersheds crossed by the proposed pipeline corridor in the Black Pines to Hope Segment. Additional information about the watercourses crossed by the proposed pipeline corridor within each watershed is provided in the Fisheries (British Columbia) Technical Report of Volume 5C.

TABLE 5.7-11

WATERSHEDS CROSSED BY THE PROPOSED PIPELINE CORRIDOR IN THE BLACK PINES TO HOPE SEGMENT

Watershed	Total Drainage Area	RK Range(s)
Lower North Thompson River	4,911 km²	RK 811.9 to RK 840.9
Thompson River	3,617 km²	RK 840.9 to RK 853.2 RK 856.5 to RK 857.8
South Thompson River	3,666 km²	RK 853.2 to RK 856.5 RK 857.8 to RK 875.6
Lower Nicola River	3,675 km²	RK 875.6 to RK 991.4
Fraser Canyon	5,158 km²	RK 991.4 to RK 1057.6

5.7.4.2 Areas of Special Interest

The proposed pipeline corridor crosses Lac du Bois Grasslands Protected Area from RK 829 to RK 836.8 and from RK 842.4 to RK 843.9 and crosses 17 watercourses within the Protected Area. The Coquihalla Summit Recreational Area is also crossed by the proposed pipeline corridor, from RK 992.4 to RK 1005.1. There are 12 proposed watercourse crossings in the Coquihalla Summit Recreational Area. There are no national parks, Environmentally Significant Areas, Canadian or BC Heritage Rivers, fisheries sensitive watersheds or any other areas of special interest related to fish and fish habitat along the proposed pipeline corridor for the Black Pines to Hope Segment.

5.7.4.3 Hydrometric Data

The Water Survey of Canada maintains hydrometric stations on several watercourses crossed by the proposed pipeline corridor in this segment (Table 5.7-12). The stations on the Coquihalla and Thompson rivers (near Hope and Kamloops, respectively) are located within 1 km of a proposed crossing location. In the Coquihalla River, lowest mean monthly flows occur in August (12 m^3/s) and the highest monthly mean flow is June (78.5 m^3/s). In the Thompson River, low mean monthly flow occurs in winter (*i.e.*, March) and the mean monthly high flow is in the spring/early summer (*i.e.*, June). Additional information about each station and the monthly mean flows can be found in Section 5.3.

TABLE 5.7-12

SUMMARY OF STREAMFLOWS FROM HYDROLOGICAL STATIONS NEAR THE PROPOSED PIPELINE CORRIDOR IN THE BLACK PINES TO HOPE SEGMENT

Watercourse Name	Station Name, Station Number	Years Station Data Available	Approximate Location of Station Relative to the Nearest RK	Month and Mean Monthly Discharge (m^3/s) During Lowest Flow Period	Month and Mean Monthly Discharge (m^3/s) During Highest Flow Period
Thompson River	Thompson River at Kamloops 8LF023	1911 to 2011	Within 1 km of RK 846.8	March 3.411 m^3/s	June 7.114 m^3/s
Coquihalla River	Coquihalla River near Hope 08MF003	1911 to 1983	Within 1 km of RK 1043.2	August 12.0 m^3/s	June 78.5 m^3/s

Sources: Environment Canada 2013h,i

5.7.4.4 Fish-Bearing Crossings

Along the Black Pines to Hope Segment, the desktop review identified that fish are still harvested by many Aboriginal communities. Kokanee, steelhead, rainbow trout, cutthroat trout, suckerfish, whitefish, burbot, sturgeon and salmon are among the fish caught in this region. Migrating salmon are caught in the Thompson River and the Nicola River (AMEC Earth and Environmental 2010). Bull trout and Dolly Varden char are fished at the Coldwater River and at the Fraser River (Katzie Development Corporation 2011).

Based on historical data and field studies conducted for the Project (see Fisheries [British Columbia] Technical Report of Volume 5C), 39 of the proposed crossings were identified as fish-bearing. Table 5.7-13 provides a list of fish-bearing water crossings, their location along the proposed pipeline corridor, watershed, sensitivity rating, instream work windows, least risk biological windows and the presence of indicator species. Additional information about these crossings, including known fish species presence, recommended crossing methods, water quality parameters, watercourse characteristics, and fish habitat ratings is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing Atlas (Appendix B).

The fish-bearing watercourse crossings include at least one proposed crossing of each of the Thompson, Nicola, Coldwater and Coquihalla rivers.

Sensitivity ratings were established using the professional judgment of a QEP and are based on the fish species present at the time of the field assessment or previously documented within a given system, flow regime (*i.e.*, seasonal or perennial) or the habitat type available for each life history stage (*e.g.*, spawning) of the key fish species present. This closely follows criteria defined by DFO (CAPP *et al.* 2005). A sensitivity rating allows the use of a risk assessment approach to determine the overall risk to fishes and their habitat at a given watercourse crossing. Additional details about the fish and fish habitat sensitivity ratings are provided in Section 5.7.2.4 and the Fisheries (British Columbia) Technical Report of Volume 5C.

NCDs and WETLANDS						
BC-414	847.4	Unnamed Drainage (Wetland)	Thompson River	Low	None (none)	None (Open)
BC-433	865.2	Anderson Creek	South Thompson River	High	Rainbow trout/steelhead (rainbow trout/steelhead)	July 22 to August 15 (July 22 to October 31)

Notes:
1 Project watershed as described in detail in Section 5.7.5.1.
2 Methodology for determination of watercourse sensitivity is described in detail in the Fisheries (British Columbia) Technical Report of Volume 5C.
3 Blended indicator (*i.e.*, bull trout/Dolly Varden, rainbow trout/steelhead) presence indicates that at least one species is found in the watercourse.
4 Watercourses requiring ongoing studies are identified in Appendix F of the Fisheries (British Columbia) Technical Report of Volume 5C.
* Located in a community watershed and received a S1 to S4 (fish-bearing) stream classification status as per BC OGC's *Environmental Protection and Management Regulation* (see Section 4.1.2 of the Fisheries (British Columbia) Technical Report of Volume 5C).

5.7.4.5 Riparian Habitat

Riparian habitat composition at watercourses crossed by the proposed pipeline corridor within the Black Pines to Hope Segment (RK 811.8 to RK 1043.7) varies. Within the Black Pines to Hope Segment and both power lines, the main biogeoclimatic zone is IDF. Riparian habitat within this zone is mainly comprised of dense, closed-canopy spruce (coniferous) forest.

5.7.4.6 Field Results

Fish and fish habitat assessments (Fisheries [British Columbia] Technical Report of Volume 5C) were conducted in order to document existing fish and fish habitat conditions at proposed watercourse crossings with fish and fish habitat. Information will be provided to DFO to assist with any case-specific reviews of water crossings they may need to conduct.

A total of 303 potential watercourse crossings were assessed within the Black Pines to Hope Segment. One watercourse (*i.e.*, Shuta Creek) has been assigned a stream classification based on adequate historical information. Overall, 39 watercourse crossings are considered to be fish-bearing and 265 are considered to be nonfish-bearing based on sites assessed in the field and historical information. Of these, 15 watercourse crossings require ongoing studies to confirm stream classification (see Appendix F of the

Fisheries [British Columbia] Technical Report of Volume 5C). Overall, 39 watercourse crossings are considered to be fish-bearing and 265 are considered to be nonfish-bearing based on sites assessed in the field and historical information. A summary of stream classifications for all fish-bearing and nonfish-bearing drainages crossed by the proposed pipeline corridor along the Black Pines to Hope Segment is presented in Table 5.7-14.

TABLE 5.7-14

STREAM CLASSIFICATIONS OF THE POTENTIAL CROSSINGS INVESTIGATED ALONG THE BLACK PINES TO HOPE SEGMENT

Classification[1]	Total Number
Fish-bearing	
S1A	1
S1B	11
S2	10
S3	13
S4	2
NCD-W/Wetlands	2
Nonfish-bearing	
S5	16
S6	58
NCDs	73
NVCs	112
NCD-W/Wetlands	6

Note: 1 Classification refers to BC Stream Classification System (BC MOF 1995).

Of the 39 proposed fish-bearing crossings in the Black Pines to Hope Segment, 30 were rated as High sensitivity while the remaining 9 fish-bearing crossings were rated as Low sensitivity (Table 5.7-14 of this volume and Section 5.3 of the Fisheries [British Columbia] Technical Report of Volume 5C).

Indicator Species

Information on indicator species captured or observed during the fisheries field program is discussed in Sections 5.7.13 to 5.7.17.

Species of Management Concern

No *SARA*-listed species were captured or observed in the Black Pines to Hope Segment during the 2012/2013 fisheries field program. Capture or observation of provincially listed or COSEWIC-listed species included bull trout (Blue-listed [BC CDC 2013a]), chiselmouth (Blue-listed [BC CDC 2013a]) and interior Fraser coho (Endangered under COSEWIC [2013a]). Chiselmouth were captured in the Nicola River LSA; capture data for bull trout and coho are discussed in Sections 5.7.13 and 5.7.15. Additional information about species of management concern captured or observed during the 2012/2013 fisheries field program is provided in the Fisheries [British Columbia] Technical Report of Volume 5C.

5.7.5 General Information - Hope to Burnaby Segment

The Hope to Burnaby Segment, from RK 1043.7 to RK 1179.8, is located entirely within the Fraser River Basin. There are 131 proposed crossings along this segment, of which 84 are crossings of watercourses (*i.e.*, having defined beds and banks), including the Chilliwack/Vedder and Fraser rivers.

The Chilliwack River originates in North Cascades National Park in Washington State and flows north into Chilliwack Lake and then west for approximately 61 km to its confluence with the Fraser River. Below Vedder Crossing, the Chilliwack River becomes the Vedder River. The Chilliwack/Vedder River converges with the Sumas River approximately 3.5 km upstream of the confluence with the lower Fraser River. There are three proposed crossings of the Chilliwack/Vedder River (RK 1102.1, RK 1102.3, RK 1102.4) and one proposed crossing of the Sumas River (RK 1114.6) in the Hope to Burnaby Segment.

The Fraser River is the largest watercourse crossed by the proposed pipeline corridor along this segment. The lower Fraser River drains into the Strait of Georgia approximately 30 km downstream of the proposed crossing location. This portion of the lower Fraser River is important, as salmon undergo physiological changes in this region to acclimatise between a saline and freshwater environment. Additional information about the Fraser River can be found in Section 5.7.2. The Fraser River is crossed once, at RK 1168.9, in the Hope to Burnaby Segment.

The following subsections describe the watersheds, areas of special interest, hydrometric data, fish-bearing watercourses, riparian habitat and field results along the Hope to Burnaby Segment.

5.7.5.1 Watersheds

The Hope to Burnaby Segment lies entirely within the Fraser River Basin and traverses several watersheds. The proposed pipeline corridor crosses the Harrison River, Chilliwack River and Lower Fraser River watersheds (BC MFLNRO 2008a).

Table 5.7-15 provides the drainage areas and RK range(s) for each of the watersheds crossed in the Hope to Burnaby Segment. Additional information about the watercourses crossed by the proposed pipeline corridor within each watershed is provided in the Fisheries (British Columbia) Technical Report of Volume 5C.

TABLE 5.7-15

WATERSHEDS CROSSED BY THE PROPOSED PIPELINE CORRIDOR IN THE HOPE TO BURNABY SEGMENT

Watershed	Approximate Drainage Area	RK Range(s)
Harrison River	3,007 km²	RK 1057.2 to RK 1081.1
Chilliwack River	1,209 km²	RK 1081.1 to RK 1117.4
Lower Fraser River	4,679 km²	RK 1117.4 to RK 1179.8

5.7.5.2 Areas of Special Interest

The proposed pipeline corridor traverses F.H Barber Provincial Park from RK 1062.8 to RK 1062.8 and there are no crossings of watercourses in the park. There are two proposed watercourse crossings in Surry Bend Regional Park, which is traversed by the proposed pipeline corridor from RK 1160.5 to RK 1163.7. Cheam Lake Wetlands Regional Park is also crossed by the proposed pipeline corridor, from RK 1079.9 to RK 1080.0 and RK 1080.1 to RK 1080.4. There are no national parks, Environmentally Significant Areas, Canadian Heritage Rivers, fisheries sensitive watersheds or any other areas of special interest related to fish and fish habitat along the proposed pipeline corridor in the Hope to Burnaby Segment.

5.7.5.3 Hydrometric Data

The Water Survey of Canada maintains a hydrometric station on the lower Fraser River at Mission, BC approximately 47 km upstream of the proposed crossing location (Table 5.7-16). The flow data indicates low mean monthly flows occur in the winter (*i.e.*, February) and highest mean monthly flows occur in the spring/early summer (*i.e.*, June).

TABLE 5.7-16

SUMMARIES OF STREAMFLOWS FROM HYDROLOGICAL STATIONS NEAR THE PROPOSED PIPELINE CORRIDOR IN THE HOPE TO BURNABY SEGMENT

Watercourse Name	Station Name, Station Number	Years Station Data Available	Approximate Location of Station Relative to the Proposed Pipeline Corridor	Month and Mean Monthly Discharge (m^3/s) During Lowest Flow Period	Month and Mean Monthly Discharge (m^3/s) During Highest Flow Period
Fraser River	Lower Fraser River at Mission 08MH024	1911 to 2011	47 km upstream of RK 1168.9	February 1,400 m^3/s	June 8,180 m^3/s

Source: Environment Canada 2013j

5.7.5.4 Fish-Bearing Crossings

Along the Hope to Burnaby Segment, the desktop review identified that fish are still harvested by many Aboriginal communities. In particular, salmon fishing is of great importance to the Aboriginal communities in the region. TEK participants reported that fish are generally harvested from the spring to the fall and each family typically harvests from 50 to 200 salmon annually. The timing and location of the salmon runs historically dictated seasonal movements and locations of habitation sites for many communities.

Based on historical data and field studies conducted for the Project (see Fisheries [British Columbia] Technical Report of Volume 5C), 59 of the proposed crossings were identified as fish-bearing Table 5.7-17 provides a list of fish-bearing water crossings, their location along the proposed pipeline corridor, watershed, sensitivity rating, instream work windows, least risk biological windows and the presence of indicator species. Additional information about these crossings, including known fish species presence, recommended crossing methods, water quality parameters, watercourse characteristics and fish habitat ratings is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing Atlas (Appendix B).

The fish-bearing watercourse crossings include one crossing of each of the Fraser, Sumas and Chilliwack rivers (Table 5.7-17).

Sensitivity ratings were established using the professional judgment of a QEP and are based on the fish species present at the time of the field assessment or previously documented within a given system, flow regime (*i.e.*, seasonal or perennial) or the habitat type available for each life history stage (*e.g.*, spawning) of the key fish species present. This closely follows criteria defined by DFO (CAPP *et al.* 2005). A sensitivity rating allows the use of a risk assessment approach to determine the overall risk to fishes and their habitat at a given watercourse crossing. Additional details about the fish and fish habitat sensitivity ratings are provided in Section 5.7.2.4 and the Fisheries (British Columbia) Technical Report of Volume 5C.

Notes:
1 Project watershed as described in detail in Section 5.7.1.1.
2 Methodology for determination of watercourse sensitivity is described in detail in the Fisheries (British Columbia) Technical Report of Volume 5C.
3 Blended indicator species (*i.e.*, bull trout/Dolly Varden, rainbow trout/steelhead) indicates that at least one species is found in the watercourse.
4 Watercourses requiring ongoing studies are identified in Appendix F of the Fisheries (British Columbia) Technical Report of Volume 5C.
* Indicates unidentified species because it was only observed, therefore; species level could not be positively identified.

5.7.5.5 Riparian Habitat

Riparian habitat composition at watercourses crossed by the proposed pipeline corridor within the Hope to Burnaby Segment (RK 1043.7 to RK 1179.8) varies. Within the Hope to Burnaby Segment the main biogeoclimatic zone is CWH. Riparian habitat within this zone is mainly comprised of mixed deciduous and coniferous trees; western hemlock, western red cedar, ambilis fir, yellow cedar, Douglas-fir, grand fir, western white pine and bigleaf maple.

5.7.5.6 Field Results

Fish and fish habitat assessments (Fisheries [British Columbia] Technical Report of Volume 5C) were conducted in order to document existing fish and fish habitat conditions at proposed watercourse crossings with fish and fish habitat. Information will be provided to DFO to assist with any case-specific reviews of water crossings they may need to conduct. A total of 105 potential watercourse crossings were assessed within the Hope to Burnaby Segment. Four sites (*i.e.*, two unnamed tributaries to Yorkson Creek [BC-766 and BC-767], Yorkson Creek and an unnamed tributary to the Fraser River [BC-773]) have been assigned a stream classification based on adequate historical information. Overall, 59 watercourse crossings are considered to be fish-bearing and 50 are considered to be nonfish-bearing based on sites assessed in the field and historical information. Of these, 26 proposed watercourse crossings require ongoing studies to confirm stream classification (see Appendix F of the Fisheries [British Columbia] Technical Report of Volume 5C). A summary of stream classifications for all fish-bearing and nonfish-bearing drainages crossed by the proposed pipeline corridor along the Hope to Burnaby Segment is presented in Table 5.7-18.

TABLE 5.7-18

STREAM CLASSIFICATIONS OF POTENTIAL CROSSINGS INVESTIGATED ALONG THE HOPE TO BURNABY SEGMENT

Classification	Total Number
Fish-bearing	
S1A	1
S1B	8
S2	19
S3	27
S4	3
Wetland/Fish Sensitive Zone	1
Nonfish-bearing	
S5	10
S6	16
NCDs	11
NVCs	11
NCD-W/Wetlands	2

Note: 1 Classification refers to BC Stream Classification System (BC MOF 1995).

Of the 59 fish-bearing crossings in the Hope to Burnaby Segment, 54 were rated as high sensitivity while 5 were rated as low sensitivity (Table 5.7.18 of this volume and Section 5.6 of the Fisheries [British Columbia] Technical Report of Volume 5C).

Indicator Species

Information on indicator species captured or observed during the fisheries field program is discussed in Sections 5.7.13 to 5.7.17.

Species of Management Concern

No *SARA*-listed species were captured or observed along the Hope to Burnaby Segment during the 2012/2013 fisheries field program; however, ongoing studies are required at Semmihault and Stoney creeks, and there is the potential for capture of Salish sucker or Nooksack dace (both species are Endangered under *SARA* and Red-listed provincially). Salish sucker has previously recorded in Semmihault Creek, Salmon River and Chilliwack Creek. Nooksack dace has been previously recorded in Salmon River and Stoney Creek. Historical records for provincially-listed species present in watercourses crossed by the proposed pipeline corridor included bull trout (Blue-listed) (BC CDC 2013a) (see Appendix A of the Fisheries [British Columbia] Technical Report of Volume 5C for specific crossings at which bull trout has been historically reported). Bull trout were captured during the 2012/2013 fisheries field program, and these results are discussed in Section 5.7.13. Additional information about fish species of management concern captured or observed during the 2012/2013 fisheries field program is provided in the Fisheries [British Columbia] Technical Report of Volume 5C.

5.7.6 General Information - Burnaby to Westridge Segment

The Burnaby to Westridge Segment, from RK 0 to RK 3.6, is located entirely within the Fraser River Basin and traverses the Lower Fraser River and Squamish River watersheds. There are no proposed crossings of any named creeks or rivers in the Burnaby to Westridge Segment, however, there is one proposed watercourse crossing at RK 1182.5.

In particular, salmon fishing is of great importance to the Aboriginal communities in the region. The timing and location of the salmon runs historically dictated seasonal movements and locations of habitation sites for many communities.

The following subsections describe the watersheds, areas of special interest, hydrometric data, fish-bearing watercourses, riparian habitat and field results along the Burnaby to Westridge Segment.

5.7.6.1 Watersheds

The Burnaby to Westridge Segment traverses the Lower Fraser River Watershed and the Squamish River Watershed. Table 5.7-19 provides the drainage area and RK range for the watersheds crossed in the Burnaby to Westridge Segment. Additional information about the watercourses crossed by the proposed pipeline corridor within the watershed is presented in the Fisheries (British Columbia) Technical Report of Volume 5C.

TABLE 5.7-19

WATERSHEDS CROSSED BY THE PROPOSED PIPELINE CORRIDOR IN THE BURNABY TO WESTRIDGE SEGMENT

Watershed	Approximate Drainage Area	RK Range
Lower Fraser River Watershed	4,679 km^2	RK 0 to RK 1.6
Squamish River	105.4 km^2	RK 1.6 to RK 3.6

5.7.6.2 Areas of Special Interest

There are no provincial or national parks, Environmentally Significant Areas, Canadian or BC Heritage Rivers or any other areas of special interest related to fish and fish habitat along the proposed pipeline corridor in the Burnaby to Westridge Segment.

5.7.6.3 Hydrometric Data

There are no hydrometric stations on any watercourses crossed by the proposed pipeline corridor in the Burnaby to Westridge Segment.

5.7.6.4 Fish-Bearing Crossings

Along the Burnaby to Westridge Segment, the desktop review identified that fish are still harvested by many Aboriginal communities. Kwikwetlem First Nation members historically moved to the Lower Fraser River area in the summer to fish for salmon and sturgeon. A fishing camp on the south shore of the Fraser River near the Pattullo Bridge (approximately 4 km west of KP 1136) was used by a number of Aboriginal communities. Villages and fishing camps were also located along the north Fraser River shoreline from the Pitt River to New Westminster approximately 3 km north of RK 1164 to 5 km south of RK 1178 (Kwickwetlem First Nation 2007). In addition to salmon, the Kwikwetlem fish for eulachon, trout, catfish, and carp in the Fraser River (crossed at RK 118.8) and the Pitt River (approximately 3 km north of RK 1164) (Kwickwetlem First Nation 2007). Additional information on ATK fishing sites can be found in the Fisheries (British Columbia) Technical Report of Volume 5C. While salmon such as Chinook, coho and kokanee constitute the main fishery for the region, steelhead, rainbow trout, cutthroat trout, and burbot are also fished (AMEC Earth and Environmental 2010).

Based on historical data and field studies conducted for the Project (see Fisheries [British Columbia] Technical Report of Volume 5C), the proposed crossing was identified as non-fish-bearing. Additional information about this nonfish-bearing watercourse is provided in the Fisheries [British Columbia] Technical Report of Volume 5C.

5.7.6.5 Riparian Habitat

Within the Burnaby to Westridge Segment the main biogeoclimatic zone is Coastal Western Hemlock (CWH). Riparian habitat within this zone is mainly comprised of: mixed deciduous and coniferous trees; western hemlock; western red cedar; ambilis fir; yellow cedar; Douglas-fir; grand fir; western white pine; and bigleaf maple.

5.7.6.6 Field Results

The watercourse in the Burnaby to Westridge Segment was assessed during the 2012/2013 fisheries field program and was assigned a stream classification of S6. Refer to the Fisheries (British Columbia) Technical Report of Volume 5C for additional information.

5.7.7 Arctic Grayling

Populations of Arctic grayling (*Thymallus arcticus*) occupy three major watersheds in Alberta: the Hay; Peace; and Athabasca river watersheds. With respect to temperature, water levels, gradients and winter conditions, Arctic grayling live in environmentally variable conditions compared to other fish species that require stable environments. Arctic grayling spawn in the spring once water temperatures reach 5°C to 10°C. Unlike many other salmonids, Arctic grayling are broadcast spawners and do not construct redds. They are confined to the cold and coolwater streams, rivers and lakes, usually occupying boreal and foothill rivers and streams and occasionally small lakes.

Population declines, particularly in the southern portions of their range in Alberta, are often attributed to pollution, habitat degradation, fragmentation, increasing water temperatures and overharvest by anglers (Alberta Sustainable Resource Development [ASRD] and Alberta Conservation Association [ACA] 2005, Berry 1998). Arctic grayling are highly mobile and use different reaches of the stream. Habitat fragmentation disrupting Arctic grayling movement is one of the biggest contributors affecting populations (MacPherson and Furukawa 2010).

Provincially, Arctic grayling are listed as Sensitive by the General Status of Alberta Wild Species 2010 (ASRD 2011). Arctic grayling are neither *SARA* or COSEWIC listed. Alberta has implemented a management and recovery plan for Arctic grayling (Berry 1998) and Alberta's Endangered Species Conservation Committee (ESCC) has identified Arctic grayling as a Species of Special Concern (AESRD 2012b). Arctic grayling have not been considered for a status designation by the COSEWIC, but are considered to be an immediate priority candidate for status evaluation (COSEWIC 2013b).

Arctic grayling was selected as an indicator species in Alberta because of its provincial listing and the distribution of Arctic grayling in four watersheds along the Edmonton to Hinton Segment, namely the Pembina River, Lower McLeod River, Upper McLeod River and Athabasca River watersheds (Table 5.7-1). Based on the existing data and the results of the aquatic assessment, Arctic grayling may be found in seven watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Table 5.7-6).

Refer to the Fisheries (Alberta) Technical Report of Volume 5C for additional information on the life history phases and biology of the Arctic grayling as well as the watercourses at which this indicator species was captured or observed.

5.7.8 Athabasca Rainbow Trout

Athabasca rainbow trout (*Oncorhynchus mykiss*) are an indigenous stock of rainbow trout in Alberta restricted to an area less than 2,000 km^2 within the Upper Athabasca River watershed, its tributaries and headwater streams including the McLeod, Berland, Wildhay and Freeman rivers (ASRD and ACA 2009). Although Athabasca rainbow trout are not considered to be a distinct subspecies, COSEWIC guidelines recognize Athabasca rainbow trout populations as a designatable unit below the species level (ASRD and ACA 2009). Athabasca rainbow trout have a general status of At Risk in Alberta (ASRD 2011). Athabasca rainbow trout are neither *SARA* or COSEWIC listed. Rainbow trout thrive in cool waters where they prefer temperatures under 20°C, but can withstand temperatures up to 24°C (Nelson and Paetz 1992). Athabasca rainbow trout are known to spawn later in the spring, grow more slowly and mature at a smaller size than that of Alberta's introduced rainbow trout populations and are thought to be better adapted to colder, less productive headwater streams (ASRD and ACA 2009).

Athabasca rainbow trout was selected because of its provincial listing and its distribution across three watersheds along the Edmonton to Hinton Segment, namely Lower McLeod River, Upper McLeod River and Athabasca River watersheds (Table 5.7-1). Based on the historical data and the results of the fisheries field program, Athabasca rainbow trout may be found in 10 watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Table 5.7-6).

Refer to the Fisheries (Alberta) Technical Report of Volume 5C for additional information on the life history phases and biology of the Athabasca rainbow trout as well as the watercourses at which this indicator species was captured or observed.

5.7.9 Bull Trout

Bull trout (*Salvelinus confluentus*) have been designated a Species of Special Concern by the Alberta ESCC (AESRD 2012b) and are listed under COSEWIC as Threatened and Special Concern, depending on population (see Table 4.3 of the Fisheries [Alberta] Technical Report of Volume 5C) (COSEWIC 2013a). Bull trout are not listed under Schedule 1 of *SARA*. A management and recovery plan for the species has been implemented (ASRD 2012). Bull trout are frequently referenced as having the most sensitive habitat requirements among trout and char species in western North America (Brewin *et al.* 2001, Mackay *et al.* 1997). They are a late summer to early fall spawning species that requires clean gravels and groundwater inflow for spawning. They are often a top predator in the ecosystems where they occur. Their susceptibility to angler overharvest, slow maturity and sensitive habitat requirements, as well as competition from introduced non-native species and habitat fragmentation, are frequently cited as factors contributing to the species decline through most of their range in North America (*e.g.*, Berry 1994, P. Brewin and M. Brewin 1997, Pollard and Down 2001, Post and Johnston 2002).

Bull trout was selected as an indicator species in Alberta because of its provincial and COSEWIC listings and because of its presence in four watersheds along the Edmonton to Hinton Segment, namely Pembina River, Lower McLeod River, Upper McLeod River and Athabasca River watersheds (Table 5.7-1). Bull trout were not captured or observed at any proposed crossings along the proposed pipeline corridor during the fisheries field program in Alberta (see Table 5.7-6), however, they have been previously documented in six watercourses crossed by the proposed pipeline corridor.

Refer to the Fisheries (Alberta) Technical Report of Volume 5C for additional information on the life history phases and biology of bull trout.

5.7.10 Burbot

Burbot (*Lota lota*) are a sportfish that occur in cold lakes, rivers and small streams. Burbot prey and scavenge on fish, insect larvae and fish eggs. Burbot are a broadcast spawner, spawning in the late winter and early spring over a variety of substrates including sand and silt (Nelson and Paetz 1992). Nelson and Paetz (1992) also indicate that although their popularity as a sportfish is increasing, a large portion of the angler harvest often results from incidental catches of burbot by anglers targeting other highly desired species. Burbot are not *SARA*, COSEWIC or provincially listed as a species of concern.

Burbot was selected as an indicator species because it is a sportfish species (Government of Alberta 2013b), a winter spawner and by suggestion in the Edmonton ESA Workshop as well as its distribution in all eight watersheds along the Edmonton to Hinton Segment. Burbot may be found at 10 watercourses crossed by the proposed pipeline corridor based on historical data, and burbot were observed at Sundance Creek during the fisheries field program (Table 5.7-6).

Refer to the Fisheries (Alberta) Technical Report of Volume 5C for additional information on the life history phases and biology of burbot as well as the watercourse at which this indicator species was captured or observed.

5.7.11 Northern Pike

Northern pike (*Esox lucius*) are a coolwater sportfish species that prefer relatively shallow, weedy and clear water. They occur primarily in lakes and marshes, but are also commonly found in streams and rivers with slow to moderate currents. They are known as a voracious predator that feeds on insects as well as fish, amphibians and small mammals and birds (Nelson and Paetz 1992). Northern pike spawn in the early spring, often before all of the ice cover has melted (Berry 1999). Typical spawning areas include shallow marsh areas or flooded vegetation that forms shallow bays. The presence of vegetation is important for spawning success since their eggs stick to vegetation. Young hatchlings often remain sticking to vegetation with their yolk sacs for about two weeks and it is thought this may help them stay off the bottom where silt accumulation and lower dissolved oxygen concentrations often occur.

Although Alberta considers northern pike Secure (ASRD 2011), the species has experienced severe population declines across most of their range and the province has implemented management and recovery plans (Berry 1999). Northern pike are neither Schedule 1 of *SARA* or COSEWIC listed. Angler overharvest and habitat degradation are commonly cited in these management plans as key factors that have led to the decline of this species.

Northern pike was selected as an Alberta indicator species because it is a sportfish species (Government of Alberta 2013b) with a management and recovery strategy in place (Berry 1999) and because it is distributed in all eight watersheds crossed by the proposed pipeline corridor. Based on existing data and the results of the fisheries field program, northern pike may be found at 15 watercourses in the Edmonton to Hinton Segment (Table 5.7-6). Northern pike were captured or observed at five proposed watercourse crossings during the fisheries field program.

Refer to the Fisheries (Alberta) Technical Report of Volume 5C for additional information on the life history phases and biology of northern pike as well as the watercourses at which this indicator species were captured or observed.

5.7.12 Walleye

Walleye (*Sander vitreus*) in Alberta are found primarily in lakes and large rivers. Spawning occurs when water temperatures reach 5°C, usually in early spring and before northern pike and suckers spawn. Walleye can live up to 14 years old, reaching a maximum length of 100 cm.

Although Alberta considers walleye as Secure (ASRD 2011), the species has experienced severe population declines across most of their range and the province has implemented management and recovery plans (Berry 1995). Angler overharvest and habitat degradation are commonly cited in the management plan as key factors that have led to the decline of this species. Walleye are not *SARA*, COSEWIC or provincially listed as a species of concern.

Walleye was selected as an indicator species in Alberta because it is a sportfish species (Government of Alberta 2013b) with a management and recovery plan in place (Berry 1995) and because it is distributed in six watersheds (the Lower North Saskatchewan River, Middle North Saskatchewan River, Sturgeon River, Upper North Saskatchewan River, Pembina River and Lower McLeod River watersheds [Table 5.7-1]) in the Edmonton to Hinton Segment. Based on results of the fisheries field program and existing data, walleye may be found in 4 watercourses crossed by the proposed pipeline corridor (Table 5.7-6). Walleye were captured or observed at four proposed watercourse crossings during the fisheries field program.

Refer to the Fisheries (Alberta) Technical Report of Volume 5C for additional information on the life history phases and biology of walleye as well as the watercourses at which this indicator species were captured or observed.

5.7.13 Bull Trout/Dolly Varden

Bull trout and Dolly Varden coexist and hybridise in Coast Mountain drainages. Where the two species overlap, they are often difficult to tell apart, although their morphology is different (McPhail 2007). Dolly Varden are a true coastal and anadromous species, which regularly enters the ocean. Its distribution does not typically extend far inland (*i.e.*, past the District of Hope, BC). Dolly Varden are generally smaller than bull trout, inhabiting small streams. Bull trout are typically larger and distributed in cool waters throughout the interior, but are absent from many coastal rivers, with the exception of the Fraser River (McPhail 2007).

Bull trout are Blue-listed as a Species of Special Concern in BC (BC CDC 2013a) and the south coast population is considered a Species of Special Concern under COSEWIC. Bull trout are not listed under Schedule 1 of *SARA*. Bull trout are particularly vulnerable to angling pressure and poaching (McPhail 2007). Hybridization and competitive interactions with introduced brook trout can also cause declines in bull trout populations (McPhail 2007). The typically low densities of bull trout, low reproductive capacity, susceptibility to angling pressure and sensitivity to changes in water quality support the provincial Blue-listing of bull trout.

Bull trout/Dolly Varden was selected as an indicator species in BC because of the provincial and COSEWIC listings of bull trout and because bull trout/Dolly Varden are found in 10 Project watersheds crossed by the proposed pipeline corridor in BC (Table 5.7-2). Based on existing data and the results of the fisheries field program, bull trout/Dolly Varden may be found in 72 watercourses crossed by the proposed pipeline corridor in BC (Tables 5.7-9, 5.7-13 and 5.7-17). Bull trout/Dolly Varden were captured or observed at 39 proposed watercourse crossings during the fisheries field program.

Refer to the Fisheries (British Columbia) Technical Report of Volume 5C for additional information on the life history phases and biology of bull trout/Dolly Varden as well as the watercourses at which this indicator species was captured or observed.

5.7.14 Chinook Salmon

Chinook salmon are the largest anadromous salmon species that spawn and rear in Fraser River mainstems and tributaries. The Fraser River is also the largest Canadian producer of Chinook salmon (DFO 1999). DFO (1999) has divided Fraser River Chinook salmon into four major geographical stock complexes and three timing groups (spring-run, summer-run and late-run) (refer to Section 4.3.2 of the Fisheries [British Columbia] Technical Report of Volume 5C). Chinook salmon can be found throughout the Aquatics RSA in BC.

Chinook salmon were selected based on their presence in 10 Project watersheds crossed by the proposed pipeline corridor in BC (Table 5.7-2). Chinook salmon are neither *SARA* or COSEWIC listed. Based on existing data and results of the fisheries field program, Chinook salmon may be found in 54 watercourses crossed by the proposed pipeline corridor in BC (Tables 5.7-9, 5.7-13 and 5.7-17). Chinook salmon were captured or observed at 21 proposed watercourse crossings during the fisheries field program.

Refer to the Fisheries (British Columbia) Technical Report of Volume 5C for additional information on the life history phases and biology of Chinook salmon as well as the watercourses at which this indicator species was captured or observed.

5.7.15 Coho Salmon

Coho salmon are a Yellow-listed anadromous species in BC. The Interior Fraser population was designated as Endangered under COSEWIC in 2002 due to overexploitation and changes in marine and freshwater habitats (COSEWIC 2002). Coho salmon are not listed under Schedule 1 of *SARA*. Coho salmon spawn and rear in many coastal streams of BC; their distribution is especially extensive through the Lower Mainland portion of the Aquatics RSA which includes many tributaries to the lower Fraser River (DFO 2013). The upper and middle Fraser River Basin, particularly the Thompson River and its tributaries, are also extremely important for coho salmon reproduction in BC. Coho salmon do not migrate as far up the Fraser River system as Chinook salmon or sockeye salmon, but reach the headwaters of the North and South Thompson rivers. Interior Fraser River coho salmon have been divided into five subpopulation groups based on genetics (refer to Section 4.3.3 of the Fisheries [British Columbia] Technical Report of Volume 5C).

Coho salmon was selected as an indicator species in BC because of its COSEWIC listing and because it is found in 11 Project watersheds crossed by the proposed pipeline corridor in BC (Table 5.7-2). Based on existing data and the results of the fisheries field program, coho salmon may be found at 113 watercourses crossed by the proposed pipeline corridor (Tables 5.7-9, 5.7-13 and 5.7-17) Coho salmon were captured or observed at 74 proposed watercourse crossings during the fisheries field program.

Refer to the Fisheries (British Columbia) Technical Report of Volume 5C for additional information on the life history phases and biology of coho salmon as well as the watercourses at which this indicator species was captured or observed.

5.7.16 Cutthroat Trout

Cutthroat trout are distributed widely throughout BC and coexist commonly with rainbow trout (McPhail 2007). Cutthroat trout is a polytypic species and two native subspecies, the coastal cutthroat and the westslope cutthroat, are common to BC (McPhail 2007). The main external difference between coastal and westslope cutthroat trout is the pattern of black spots on the body, however, these two subspecies also differ in their morphology, genetics, chromosome number, biology and geographic distributions (McPhail 2007).

Westslope cutthroat trout are the northern most and only interior subspecies of cutthroat trout (Hagen and Baxter 2009). They are located along the Eastern Slopes and west of the Continental Divide but have also been introduced into tributaries to the South Thompson River, the Fraser River basin, streams in southeastern BC and some lakes in the lower Peace River system (COSEWIC 2006, McPhail 2007). Westslope cutthroat in BC are listed as a Species of Special Concern due to stresses to the population associated with hybridization, increased competition with introduced species, habitat loss and degradation and increased exploitation (COSEWIC 2013b). Westslope cutthroat trout are Blue-listed provincially, indicating that they are At Risk (BC CDC 2013a). This subspecies is also listed under Schedule 1 of *SARA*. Westslope cutthroat trout have limited distribution within the South Thompson and Fraser river drainage systems (*e.g.*, tributaries to the Eagle River and Mabel Lake) (McPhail 2007). Westslope cutthroat are most common to the Kootenay and Pend d'Oreille river systems (Columbia River Basin) in the southeastern portion of the province, although a few introductions of westslope cutthroat have been made into other areas of the Fraser River system (McPhail 2007).

Coastal cutthroat trout are a Blue-listed species in BC. There are three general life history forms of coastal cutthroat within the Aquatics RSA: a non-migratory freshwater-resident form; a migratory (often adfluvial) freshwater-resident form; and a sea-run form (anadromous) (McPhail 2007). Sexual maturity for coastal cutthroat is typically reached by 3 to 6 years of age.

Cutthroat trout was selected as an indicator species in BC because of its provincial listing and because it is distributed in five project watersheds crossed by the pipeline segments in BC, namely the Fraser Canyon, Harrison River, Chilliwack River, Lower Fraser River and Squamish River watersheds (Table 5.7-2). Based on the results of the aquatic assessment and existing data, cutthroat trout may be found in 52 watercourses crossed by the proposed pipeline corridor (Tables 5.7-13 and 5.7-17). Cutthroat trout were captured or observed at 18 proposed watercourse crossings during the fisheries field program.

Refer to the Fisheries (British Columbia) Technical Report of Volume 5C for additional information on the life history phases and biology of cutthroat trout as well as the watercourses at which this indicator species was captured or observed.

5.7.17 Rainbow Trout/Steelhead

Rainbow trout are a cool water salmonoid species that is widespread throughout BC and may occur both as freshwater resident (rainbow trout) and anadromous (steelhead) populations within the Fish and Fish Habitat LSA (McPhail 2007). Rainbow trout live entirely in freshwater with possible short periods of time spent in estuarine or near-shore marine waters (Alaska Department of Fish and Game 2013). It is suggested that there are two subspecies of resident rainbow trout in BC, which includes coastal and interior forms (McPhail 2007). Rainbow trout are known to hybridise commonly with cutthroat trout (McPhail 2007).

Juvenile rainbow trout and steelhead occupy the same habitat, display similar foraging characteristics and are not distinguishable within the first few years of their life (Alaska Department of Fish and Game 2013). Juvenile steelhead will spend two to three summers in freshwater before migrating to the ocean where they grow to maturity and return to their natal streams after 1 to 4 years at sea. There are two major groups of steelhead recognized within the Fish and Fish Habitat LSA: a southern coastal group; and a southern interior group.

Rainbow trout/steelhead was selected as an indicator species in BC because it is found in all 13 Project watersheds crossed by the pipeline segments in BC (Table 5.7-2). Rainbow trout/steelhead are neither *SARA* or COSEWIC listed. Based on existing data and the results of the aquatic assessment, rainbow trout/steelhead may be found in 112 watercourses crossed by the proposed pipeline corridor (Tables 5.7-9, 5.7-13 and 5.7-17). Rainbow trout/steelhead were captured or observed at 73 proposed watercourse crossings during the fisheries field program.

Refer to the Fisheries (British Columbia) Technical Report of Volume 5C for additional information on the life history phases and biology of rainbow trout/steelhead as well as the watercourses at which this indicator species was captured or observed.

5.8 Wetland Loss or Alteration

This subsection presents a summary of the findings related to wetlands in the Wetland LSA and Wetland RSA. The indicator selected for this element discussed below is wetland function. The rationale for the selection of this indicator is provided in Section 7.2.8. The potential Project-related effects and mitigation pertaining to wetlands are discussed in Section 7.2.8. Refer to the Wetland Evaluation Technical Report of Volume 5C for additional details on the existing conditions of wetlands.

This setting discusses wetland loss or alteration within the Wetland LSA and Wetland RSA. The Wetland LSA is considered the ZOI likely to be affected by direct disturbance during construction and operations, consisting of a 300 m wide band generally from the proposed pipeline corridor (*i.e.*, 150 m on both sides of the proposed pipeline corridor centre) with site-specific tailoring to extend around larger wetland complexes that are encountered by the proposed pipeline corridor. The Wetland RSA includes all watersheds affected by the Project. The spatial boundaries of the Wetland RSA are shown on Figures 5.8-1 and 5.8-2.

Wetlands are defined as follows:

> "*…land that is saturated with water long enough to promote wetland or aquatic processes as indicated by poorly-drained soils, hydrophytic vegetation and various kinds of biological activity which are adapted to a wet environment*" (National Wetland Working Group [NWWG] 1997).

This wetland definition encompasses a wide range of ecosystems, from semi-terrestrial fens, bogs and swamps to semi-aquatic marshes and shallow open water complexes. Wetlands include a broad range of ecosystem types, from those permanently flooded by shallow water and dominated by aquatic organisms to forested sites with merely moist soils.

ALL LOCATIONS APPROXIMATE

Wetlands surveyed were classified to both class and form hierarchical levels according to the Canadian Wetland Classification System (NWWG 1997) and the Mackenzie and Moran (2004) Wetland Classification System in BC. Table 3.6-1 of the Wetland Evaluation Technical Report (Volume 5C) lists wetland characteristics of the dominant wetland classes of the Canadian Wetland Classification System that commonly occur in the wetland regions encountered by the proposed pipeline corridor. The dominant wetland classes include bogs, fens, swamps, marshes and shallow open water wetlands.

Wetland data collection for the Project utilized both helicopter reconnaissance and ground-based wetland surveys where ground access was available. The helicopter reconnaissance, used to gather high-level delineation and classification information for wetlands, and the ground-based surveys were completed by wetland ecologists in 2012. The field program focused on the proposed pipeline corridor.

An additional helicopter reconnaissance was conducted in April and May 2013 along segments of the proposed pipeline corridor that were finalized subsequent to the 2012 field program completion.

Following the spring 2013 overflights, all wetlands identified during the helicopter reconnaissance were ground-truthed where land access was available. The intent is that all wetlands within the proposed pipeline corridor will be surveyed on the ground prior to Project construction. The multiple helicopter reconnaissances conducted at various times throughout the year (*i.e.*, spring and fall) give a better understanding of the seasonal fluctuations of the local hydrologic regime.

Wetland function can be described as the ability of wetlands to perform numerous hydrological, biogeochemical and habitat-related functions within an ecosystem. These functions include: flood control; ground water recharge; water quality functions, such as water purification as well as sediment and nutrient retention; carbon sequestration; substrate protection; and maintaining biodiversity. Wetland function can change throughout the year and from year to year (*e.g.*, from times of drought to excessive precipitation). Given changing conditions, wetland function is used as a general description of the ability of a wetland to perform a variety of functions. A literature review summary for wetland function is provided below (*e.g.*, Hoorens *et al.* 2010, Houlahan *et al.* 2006, Hunt *et al.* 1999, Kellner and Halldin 2002, McLatchey and Reddy 1998, Mitsch and Gosselink 2007, Price *et al.* 2005, van der Kamp and Hayashi 1998, Vitt 2000). Description of wetland function conditions identified can be found in Section 7.0 of this volume and in the Wetland Evaluation Technical Report of Volume 5C. The methods used to evaluate wetland function, which were developed through consultation with Environment Canada can be found in the Wetland Evaluation Technical Report of Volume 5C.

Wetland function was evaluated at each wetland visited during the ground-based field work. The function of wetlands crossed by the proposed pipeline corridor are reported on the premise that disturbed wetlands would be revisited in the years following construction to document the progress of function returning to the wetland system after pipeline construction. Wetland function documented during the existing (*i.e.*, pre-construction) condition ground-based wetland surveys will be compared to wetland function observed along the reclaimed (*i.e.*, post-construction) construction right-of-way. The results of this comparison will be used to measure the effectiveness and efficiency of mitigation and reclamation measures, to ensure that wetlands are on the trajectory to returning to pre-construction functional condition and provide support to the determination of loss or “no net loss” of wetland function. Data collection methods are based on the Wisconsin Rapid Assessment Methodology (Wisconsin Department of Natural Resources 2001), Manual for the Wetland Ecosystem Services Protocol for the US (Adamus 2011), Riparian Health Assessment for Lakes, Sloughs and Wetlands (Ambrose *et al.* 2009), Riparian Health Assessment for Streams and Small Rivers (Fitch *et al.* 2001), Ontario Wetland Evaluation System (Ontario Ministry of Natural Resources 1993) and are part of an Environment Canada recommended approach (Hanson *et al.* 2008). These methods were presented to Environment Canada through consultation and no issue was presented at that time.

Wetlands provide a nutrient-rich habitat for a variety of plants and animals that are important to Aboriginal communities for subsistence harvesting and sustaining traditional practices. Large mammals found in and around these areas, such as caribou and moose, as well as small furbearers make these ecosystems important for Aboriginal trapping and hunting activities. Medicinal and other culturally important plants, such as the diamond willow, are also frequently found in wetland regions.

In 2012 and 2013, TEK was gathered and recorded during the wetlands field surveys. During the field surveys, traditional methods of resource procurement were discussed, as well as modern methods currently employed. Seasonality of resource harvesting, species of traditional importance, classification of wetland areas and descriptions of traditional resources contained within the different wetland areas was also important information shared by the Aboriginal participants. Geographical locations were identified, as were areas that are not used and the reasons why. Potential mitigation measures to reduce any Project-related effects on a resource were also discussed during the wetland field surveys.

5.8.1 Edmonton to Hinton Segment

The proposed pipeline corridor along the Edmonton to Hinton Segment is located within: two ecozones (*i.e.*, Prairies and Boreal Plains) and three ecoregions of Canada (*i.e.*, Aspen Parkland, Boreal Transition and Western Alberta Upland) (Agriculture and Agri-Food Canada 2013, Ecological Stratification Working Group 1995); two Wetland Regions of Canada (*i.e.*, Continental and Transitional Mid-Boreal) (Government of Canada 1986); and five natural subregions of Alberta, including the Central Parkland, Dry Mixedwood, Central Mixedwood, Lower Foothills and Montane Natural Subregions (Natural Regions Committee 2006b).

Alberta represents approximately 7% of Canada's land mass. Wetlands in Alberta cover approximately 20% of the province, over 90% of which are peatlands in the boreal region, while the remaining 5% to 10% are mineral wetlands (*i.e.*, marshes, swamps and shallow open water wetlands) in the parkland and prairie region (NWWG 1986, Tarnocai 1984, Vitt *et al.* 1996).

In Alberta, the proposed pipeline corridor does not encounter the 200 m setback of any provincially identified piping plover waterbodies (AESRD 2010-2012). The proposed pipeline corridor does encounter the 1,000 m setback of provincially identified colonial nesting bird waterbodies and the 800 m setback of many provincially identified trumpeter swan waterbodies (AESRD 2010-2012).

The proposed pipeline corridor along the Edmonton to Hinton Segment does not cross any Migratory Bird Sanctuaries (Environment Canada 2013n), Western Hemisphere Shorebird Reserves (Western Hemisphere Shorebird Reserve Network [WHSRN] 2013), Important Bird Areas (IBAs) (Bird Studies Canada and Nature Canada 2012) or Ramsar wetlands (Bureau of the Convention on Wetlands 2013).

Ducks Unlimited Canada (DUC) has identified three levels of priority for wetland conservation in Canada. The Edmonton to Hinton Segment travels through the DUC Level 1 Priority Landscapes, Prairie Pothole and Western Boreal Forest (DUC 2013). No DUC sites are crossed by the proposed pipeline corridor (McFarlane pers. comm.).

Provincial parks, recreational areas, protected areas and regional parks were identified within the Wetland LSA for all of the proposed pipeline segments. In Alberta, two protected areas, Nojack Provincial Recreation Area (RK 175) and Yates Natural Area (RK 222), were identified in proximity to the proposed pipeline corridor along the Edmonton to Hinton Segment. The proposed pipeline corridor is located approximately 70 m south of Nojack Provincial Recreation Area and 20 m south of the Yates Natural Area but does not cross through these areas. During the Edmonton ESA Workshop, the Wagner Natural Area was raised as a concern. This natural area is located 3.4 km to the north of the proposed pipeline corridor, however, areas that feed this natural area are crossed by the Project.

Along the Edmonton to Hinton Segment, the most common land use consists of cultivation, pasture, residential developments and linear disturbances (*e.g.*, highways, pipeline rights-of-way) which has contributed to disturbance to wetlands. For additional information on the current level of disturbance to wetlands along the Edmonton to Hinton Segment, see Appendix B in the Wetland Evaluation Technical Report of Volume 5C.

Aboriginal Traditional Knowledge

Available ATK related to wetlands along the Edmonton to Hinton Segment is limited. However, the desktop review identified concerns regarding the disruption of wetlands and "muskeg" (a colloquial term for peatlands) due to pipeline construction activities since these disruptions could result in lower animal populations and affect medicinal plants (Northern Gateway Pipelines Limited Partnership Inc. [NGPLP] 2010).

Consultation

Table 5.8-1 provides the outcomes from ESA Workshops and meetings held with federal, provincial and municipal representatives and community workshops relating to presence and characteristics of wetland areas along the Edmonton to Hinton Segment. For more information on other topics raised during these workshops and meetings, see Section 3.0 of this volume and Section 2.0 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-1

SUMMARY OF ESA WORKSHOP AND MEETING OUTCOMES

Workshop Location	Date	Outcome[1]
Edmonton, Alberta	March 4, 2013	During this workshop, it was identified that Wagner Bog and the Wagner Natural Area exist near the proposed pipeline corridor and concerns were expressed that the pipeline may potentially cut across areas feeding that region and may impact the water supply.
Spruce Grove, Alberta	October 1, 2012	Staff at the City of Spruce Grove identified some areas of environmental concerns, including wetlands/peatlands (around RK 61.5 to RK 61.9 and south of RK 59.4 to RK 59.7 along the existing TMPL right-of-way).
Yellowhead County, Alberta	October 17, 2012	Staff at Yellowhead County commented that there is a peatland area surrounding Chip Lake.
Edson, Alberta	April 23, 2013	Participants identified a bog area west of the Town of Edson that has been difficult to revegetate which many other companies have avoided.
Hinton, Alberta	April 24, 2013	Participants identified some wet areas along the proposed pipeline corridor as well as noted that there seems to be a layer of mineral soil within boggy areas about 0.6 m down indicating high water tables.

Note: 1 Terminology captured at community workshops may be colloquial in nature and may not reflect wetland classification based on the Canadian Wetland Classification System (NWWG 1997).

Results of Field Data Collection

Helicopter reconnaissances along this segment were conducted from August 16 to 17, 2012 and on May 10, 2013. Ground-based field work at wetlands along this segment with available land access permission was conducted from August 13 to 23, 2012 and from May to July 2013.

A desktop review of overflight photographs and satellite imagery was conducted to try and identify and delineate all potential wetland areas along the proposed pipeline corridor. The desktop review identified 339 wetlands (51.6 km), comprising approximately 5.2% of the proposed pipeline corridor. Wetlands crossed by the proposed pipeline corridor include 154 basin marshes, 31 riparian marshes, 59 flat swamps, 26 riparian swamps, 2 discharge swamps, 1 slope swamps, 18 basin water, 3 riparian water, 11 basin fens, 23 horizontal fens, 7 riparian fens, 2 channel fens, 1 feather fen and 1 basin bog.

The 2012 and 2013 wetland field surveys were conducted on lands where access was granted and confirmed that 261 wetlands are crossed by the proposed pipeline corridor. Wetlands crossed by the proposed pipeline corridor visited during the 2012 and 2013 ground-based wetland field surveys include 115 basin marshes, 24 riparian marshes, 46 flat swamps, 21 riparian swamps, 2 discharge swamps, 1 slope swamps, 9 basin water, 3 riparian water, 10 basin fens, 22 horizontal fens, 7 riparian fens and 1 feather fen. Typical wetland community types documented include seasonal emergent and deep marsh community types, open water community types, shrubby community types, mixedwood treed community types, broad-leaf treed community types, needle-leaf treed community types, treed community types and graminoid community types. These numbers will be updated following the completion of the 2014 supplemental field program.

Wetland functional assessments were conducted at all wetlands ground-truthed in 2012 and 2013. The results of this assessment identified that the Edmonton to Hinton Segment encounters 78 wetlands were High Functional Condition, 142 wetlands were High-Moderate Functional Condition and 41 wetlands were of Low-Moderate Functional Condition within the proposed pipeline corridor.

It was also determined that approximately 13 rare plants or rare ecological communities are associated with wetlands found along the Edmonton to Hinton Segment. Additional information on the rare ecological communities found associated with wetlands is provided in the Vegetation Technical Report of Volume 5C.

Table 5.8-2 provides a summary of the classes, approximate length of disturbance and percent of proposed pipeline corridor crossed by wetlands along the proposed pipeline corridor along the Edmonton to Hinton Segment. Additional information on wetlands along this segment, including conservation status, is provided in Section 5.1 of the Wetland Evaluation Technical Report of Volume 5C. As the Environmental Alignment Sheets were finalized prior to field work being conducted in October 2013, the numbers provided in Table 5.8-2 may differ from those provided on the Environmental Alignment Sheets of Volume 6E.

TABLE 5.8-2

SUMMARY OF WETLANDS CROSSED ALONG THE EDMONTON TO HINTON SEGMENT

Wetland Class	All Wetlands Crossed by Proposed Pipeline Corridor	Number of Ground-Truthed Wetlands Crossed by Proposed Pipeline Corridor[1]	Approximate Length of Wetland Crossed by Proposed Pipeline Corridor (m)	Percent of Proposed Pipeline Corridor Crossed
Basin Marsh	154	115	13,727	1.4
Riparian Marsh	31	24	5,486	0.6
Flat Swamp	59	46	10,433	1.1
Riparian Swamp	26	21	5,045	0.5
Discharge Swamp	2	2	465	0.05
Slope Swamp	1	1	82	0.01
Basin Water	18	9	2,139	0.2
Riparian Water	3	3	619	0.1
Basin Fen	11	10	1,983	0.2
Horizontal Fen	23	22	9,690	1.0
Riparian Fen	7	7	1,676	0.2
Channel Fen	2	--[2]	131	0.01
Feather Fen	1	1	125	0.01
Basin Bog	1	--[2]	114	0.01
Total	339	261	51,714	4

Notes: 1 Ground-truthing and functional assessments were conducted at wetlands where land access permission was available in 2012 and 2013.

2 A double dash indicates that those particular wetland classes were not ground-truthed in 2012 or 2013.

Traditional Ecological Knowledge

During the field studies along the proposed Edmonton to Hinton Segment, TEK participants reported that wetlands are complex ecosystems used by many animals. Moose, deer, elk, beaver, muskrat, ducks, geese and other birds access wetlands for food, water and protection from predators. Wetlands are abundant in willows, muskeg moss, hard woods, berries and roots, and medicinal plants that thrive in wet soils.

Participants noted that wetlands are often used as migratory routes for moose, elk, coyotes and wolves and bears are also drawn to these nutrient-rich areas. Moose will calve in wetlands where nearby tall grasses and tree cover offer protection from predators and make ideal calving beds. Muskeg moss (peat moss) is used by Aboriginal peoples for diapers, whereby the moss is harvested and hung to dry before it is used.

5.8.2 Hargreaves to Darfield Segment

The Hargreaves to Darfield Segment is located within: one ecozone (*i.e.*, Montane Cordillera) and three ecoregions of Canada (*i.e.*, Eastern Continental Ranges, Western Continental Ranges and the Mountains and Highlands) (Agriculture and Agri-Food Canada 2013, Ecological Stratification Working Group 1995); two Wetland Regions of Canada (*i.e.*, Continental Mid-Boreal and South Interior Mountain) (Government of Canada 1986); and three BGC zones of BC (*i.e.*, ICH, SBS and IDF) (BC MFLNRO 2012, Meidinger and Pojar 1991).

BC represents approximately 10% of Canada's land mass. Wetlands in BC cover approximately 3% of the province, approximately 33% of which are peatlands, while approximately 66% are mineral wetlands (*i.e.*, marshes, swamps and shallow open water wetlands) (NWWG 1986, Tarnocai 1984).

The Hargreaves to Darfield Segment does not cross any Migratory Bird Sanctuaries (Environment Canada 2013n), Western Hemisphere Shorebird Reserves (WHSRN 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Ramsar wetlands (Bureau of the Convention on Wetlands 2013) or any of the DUC Priority Landscapes (DUC 2013). No DUC sites are crossed by the proposed pipeline corridor (Harrison pers. comm.).

There were six protected areas identified within the Wetland LSA along the Hargreaves to Darfield Segment. The proposed pipeline corridor crosses two of these, Finn Creek Provincial Park and North Thompson River Provincial Park. The other four protected areas are located within the Wetland LSA at the following distances from the proposed pipeline corridor: Blue River Black Spruce Provincial Park (30 m east); Jackman Flats Provincial Park (40 m west); Eskin Creek Canyon Provincial Park (70 m west); and Chu Chua Cottonwood Provincial Park (30 m east).

Along the Hargreaves to Darfield Segment, the most common land uses consist of cultivation, pasture, residential developments, forestry and linear disturbances (*e.g.*, highways, pipeline rights-of-way) which has contributed to disturbance to wetlands. For additional information on the current level of disturbance to wetlands along the Hargreaves to Darfield Segment, see Appendix B in the Wetland Evaluation Technical Report of Volume 5C.

Aboriginal Traditional Knowledge

Available ATK related to wetlands along the Hargreaves to Darfield Segment is limited. However, the desktop review identified concerns regarding peatland areas where Labrador tea may be harvested (Lifeways of Canada Ltd. 2012, NGPLP 2010).

Consultation

Table 5.8-3 provides the outcomes community workshops relating to presence and characteristics of wetland areas along the Hargreaves to Darfield Segment. For more information on other topics raised during these workshops and meetings, see Section 3.0 of this volume and Section 2.0 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-3

SUMMARY OF COMMUNITY WORKSHOP OUTCOMES IN THE HARGREAVES TO DARFIELD SEGMENT

Workshop Location	Date	Outcome[1]
Valemount, BC	May 28, 2013	The Valemount Community Workshop identified that generally the area to the southwest of Valemount is quite wet and marshy, seasonally and permanently. They also commented on the presence of Cranberry Marsh located south of the Village of Valemount.
Blue River, BC	May 29, 2013	The Blue River Community Workshop identified the presence of a black spruce bog located south of the community which provides unique habitat. This area was felt by the participants to perhaps be a protected area, although it is not marked as a park. Participants also commented that there are many swampy areas in the general area around the Community of Blue River.
Clearwater, BC	June 5, 2013	During the Clearwater Community Workshop, participants made note that there is an abundance of wetlands around Blackpool.

Note: 1 Terminology captured at community workshops may be colloquial in nature and may not reflect wetland classification based on the Canadian Wetland Classification System (NWWG 1997).

Results of Field Data Collection

Helicopter reconnaissances along this segment were conducted from August 19 to 20, 2012 and on May 8, 2013. Ground-based field work at wetlands along this segment with available land access permission was conducted from September 27 to October 3, 2012 and from April to July 2013.

A desktop review of overflight photographs and satellite imagery was conducted to try and identify and delineate all potential wetland areas along the proposed pipeline corridor. The desktop review identified 155 wetlands (totalling approximately 27.5 km in length), comprising approximately 2.8% of the proposed pipeline corridor. Wetlands crossed by the proposed pipeline corridor include 31 basin marshes, 17 riparian marshes, 2 lacustrine marshes, 1 slope marsh, 30 flat swamps, 41 riparian swamps, 3 slope swamps, 10 basin water, 10 riparian water, 1 basin fen, 3 horizontal fens and 1 riparian fens.

The 2012 and 2013 wetland field surveys were conducted on lands where access was granted and confirmed that 106 wetlands are crossed by the proposed pipeline corridor. Wetlands crossed by the proposed pipeline corridor visited during the 2012 and 2013 ground-based wetland field surveys include 21 basin marshes, 13 riparian marshes, 1 slope marsh, 21 flat swamps, 36 riparian swamps, 3 slope swamps, 2 basin water, 6 riparian water, 1 basin fen and 2 horizontal fens. Typical wetland community types documented include seasonal emergent and deep marsh community types, open water community types, shrubby community types, mixedwood treed community types, broad-leaf treed community types, needle-leaf treed community types and graminoid community types. These numbers will be updated following the completion of the 2014 supplemental field program.

Wetland functional assessments were conducted at all wetlands ground-truthed in 2012 and 2013. The results of this assessment identified 24 wetlands that were High Functional Condition, 72 wetlands were High-Moderate Functional Condition and 10 wetlands were of Low-Moderate Functional Condition.

It was also determined that approximately 20 wetlands were associated with 4 rare plant observations and 6 rare ecological communities found along the Hargreaves to Darfield Segment. Of these rare plants and rare ecological communities, 2 are Red-listed, 6 are Blue-listed and 1 currently is not listed.

Table 5.8-4 provides a summary of the classes, length of disturbance and percent of proposed pipeline corridor crossed by wetlands along the proposed pipeline corridor in the Hargreaves to Darfield Segment. Additional information on wetlands along this segment, including conservation status, is provided in Section 5.1 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-4

SUMMARY OF WETLANDS CROSSED ALONG THE HARGREAVES TO DARFIELD SEGMENT

Wetland Class	All Wetlands Crossed by Proposed Pipeline Corridor	Number of Ground-Truthed Wetlands Crossed by Proposed Pipeline Corridor[1]	Approximate Length of Wetland Crossed by Proposed Pipeline Corridor (m)	Percent of Proposed Pipeline Corridor Crossed
Basin Marsh	31	21	3,750	0.4
Riparian Marsh	17	13	2,954	0.3
Lacustrine Marsh	2	--[2]	244	0.02
Slope Marsh	1	1	45	0.005
Flat Swamp	30	21	6,980	0.7
Riparian Swamp	41	36	8,702	0.9
Slope Swamp	3	3	524	0.1
Basin Water	10	2	931	0.1
Riparian Water	10	6	1,501	0.2
Basin Fen	1	1	9	0.001
Horizontal Fen	3	2	437	0.04
Riparian Fen	6	--[2]	1,266	0.1
Total	155	106	27,343	2.8

Notes: 1 Ground-truthing and functional assessments were conducted at wetlands where land access permission was available in 2012 and 2013.

2 A double dash indicates that those particular wetland classes were not ground-truthed in 2012 or 2013.

Traditional Ecological Knowledge

During the field studies along the proposed Hargreaves to Darfield Segment, TEK participants identified wildlife typically observed in wetland habitats including moose, beavers, fish, toads, frogs, snakes, red-winged blackbirds, chicks, minnows, migratory birds, eagles, bats, deer, bears, muskrat, caribou, hare, ducks, elk and deer. Participants explained that the diversity of the vegetation supported by wetland habitats attracts a wide range of wildlife species. Wetland vegetation identified during the field studies includes fireweed, dogbane, cottonwood, water lilies, bulrushes, thistle species, cattail, birch, bunchberry, Saskatoon berry, wild rhubarb, no-leaves plant, cedar, soapberry, mint and poplar.

5.8.3 Black Pines to Hope Segment

The Black Pines to Hope Segment is located within: one ecozone (*i.e.*, Montane Cordillera) and two ecoregions of Canada (*i.e.*, Thompson-Okanagan Plateau and Okanagan Range) (Agriculture and Agri-Food Canada 2013, Ecological Stratification Working Group 1995); three Wetland Regions of Canada (*i.e.*, Intermountain Prairie, South Coastal Mountain and Pacific Temperate) (Government of Canada 1986); and eight BGC zones of BC (*i.e.*, PP, BG, IDF, MS, CWH, ESSF and MH) (BC MFLNRO 2012, Meidinger and Pojar 1991).

BC represents approximately 10% of Canada's land mass. Wetlands in BC cover approximately 3% of the province; approximately 33% of which are peatlands, while approximately 66% are mineral wetlands (*i.e.*, marshes, swamps and shallow open water wetlands) (NWWG 1986, Tarnocai 1984).

The Black Pines to Hope Segment does not cross any Migratory Bird Sanctuaries (Environment Canada 2013n), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Ramsar wetlands (Bureau of the Convention on Wetlands 2013).

One IBA is located within the Wetland LSA along the Black Pines to Hope Segment, namely the Douglas Lake Plateau (RK 850.6 to RK 863.7) (Bird Studies Canada and Nature Canada 2012). The Douglas Lake Plateau IBA is located south of the City of Kamloops. The proposed pipeline corridor crosses a small portion of this IBA at its northern extent where it crosses Highway 5. This IBA consists of rolling BG grasslands, small marshy lakes, Douglas-fir/PP forests and aspen parkland. This area is home to a small population of American badger (Red-listed), great basin spadefoot toad (Blue-listed) and rubber boa (Yellow-listed). The Douglas Lake Plateau is an important migration breeding area for the sandhill crane (a Blue-listed, vulnerable species in BC). The number of sandhill cranes that use this area for breeding and migration staging areas represent over 1.5% of the North American population. The area is also a major migration corridor for loons, grebes, waterfowl, raptors, shorebirds, gulls and passerines. Perhaps 5-10% of the population of the flammulated owl, a nationally vulnerable species, breed within the IBA. The Lewis' woodpecker is also known to breed within the Douglas Lake Plateau IBA, though exact numbers of this nationally vulnerable species are not known. There are 10 burrowing owls (Red-listed) that have been released within this IBA at several locations. Swainson's hawk (Red-listed), ferruginous hawk and prairie falcon (Red-listed) are also known to breed within the IBA. Birds that are not common within BC that are known to breed within the Douglas Lake Plateau are bobolink (Blue-listed), Brewer's sparrow (Yellow-listed), common nighthawk (Yellow-listed), American avocet (Blue-listed), black tern (Yellow-listed) and yellow-headed blackbird (Yellow-listed) (Bird Studies Canada and Nature Canada 2012).

The Black Pines to Hope Segment encounters the DUC Level 3 Priority Landscapes. This priority level is classified as Eastern Boreal Forest since it consists of characteristics similar to those found in the eastern reaches of this forest zone (DUC 2013). No DUC conservation sites are crossed by the proposed pipeline corridor (Harrison pers. comm.).

The Black Pines to Hope Segment encounters four protected areas within the Wetland LSA. The proposed pipeline corridor crosses two of these, Lac du Bois Grasslands Protected Area and Coquihalla Summit Recreational Area. The other two protected areas are located within the Wetland LSA at the following distances from the proposed pipeline corridor: Coldwater River Provincial Park (10 m east); and Coquihalla River Provincial Park (50 m west).

Aboriginal Traditional Knowledge

Along the Black Pines to Hope Segment, the desktop review identified that several Aboriginal communities harvest wapato, a nutritious tuber that is found scattered throughout marshy areas. The harvest is collected by using canoes or by wading into the shallows and treading on the plants until the roots float to the surface (Golder Associates 2008).

Consultation

Table 5.8-5 provides the outcomes of community workshops relating to presence and characteristics of wetland areas along the Black Pines to Hope Segment. For more information on other topics raised during these workshops and meetings, see Section 3.0 of this volume and Section 2.0 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-5

SUMMARY OF COMMUNITY WORKSHOP OUTCOMES IN THE BLACK PINES TO HOPE SEGMENT

Workshop Location	Date	Outcome
Merritt, BC	June 12, 2013	The Merritt Community Workshop brought forth information on the wetland habitat found along the Nicola River at the proposed crossing location.

Results of Field Data Collection

Helicopter reconnaissances along this segment were conducted from September 22 to 23, 2012 and on May 8, 2013. Ground-based field work at wetlands along this segment with available land access was conducted from April 28 to May 7, 2013.

A desktop review of overflight photographs and satellite imagery was conducted to identify and delineate all potential wetland areas along the proposed pipeline corridor. The desktop review identified 88 wetlands (totalling approximately 10.3 km in length), comprising approximately 1.0% of the proposed pipeline corridor. Wetlands crossed by the proposed pipeline corridor include 45 basin marshes, 7 riparian marshes, 2 lacustrine marshes, 6 slope marsh, 10 flat swamps, 4 riparian swamps, 2 slope swamps, 7 basin water, 3 riparian water, 1 basin fen and 1 slope fen.

The 2012 and 2013 wetland field surveys were conducted on lands where access was granted and confirmed that four wetlands are crossed by the proposed pipeline corridor. Wetlands crossed by the proposed pipeline corridor visited during the 2012 and 2013 ground-based wetland field surveys include three basin marshes and one flat swamp. Typical wetland community types documented include seasonal emergent, alkali and deep marsh community types, open water community types, shrubby community types, broad-leaf treed community types, needle-leaf treed community types and graminoid community types. These numbers will be updated following the completion of the 2014 supplemental field program.

Wetland functional assessments were conducted at all wetlands ground-truthed in 2012 and 2013. The results of this assessment identified two wetlands were High-Moderate Functional Condition and two wetlands were of Low-Moderate Functional Condition.

It was also determined that one wetland was associated with one rare ecological community found along the Black Pines to Hope Segment. This rare ecological community is Blue-listed.

Table 5.8-6 provides a summary of the classes, length of disturbance and percent of proposed pipeline corridor crossed by wetlands along the proposed pipeline corridor in the Black Pines to Hope Segment. Additional information on wetlands along this segment, including conservation status, is provided in Section 5.1 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-6

SUMMARY OF WETLANDS CROSSED ALONG THE BLACK PINES TO HOPE SEGMENT

Wetland Class	All Wetlands Crossed by Proposed Pipeline Corridor	Number of Ground-truthed Wetlands Crossed by Proposed Pipeline Corridor[1]	Approximate Length of Wetland Crossed by Proposed Pipeline Corridor (m)	Percent of Proposed Pipeline Corridor Crossed
Basin Marsh	45	3	3,913	0.4
Riparian Marsh	7	--[2]	1,028	0.1
Lacustrine Marsh	2	--[2]	476	0.05
Slope Marsh	6	--[2]	599	0.06
Flat Swamp	10	1	1,350	0.14
Riparian Swamp	4	--[2]	941	0.1
Slope Swamp	2	--[2]	412	0.04
Basin Water	7	--[2]	781	0.08
Riparian Water	3	--[2]	411	0.04
Basin Fen	1	--[2]	195	0.02
Slope Fen	1	--[2]	187	0.02
Total	88	4	10,292	1.0

Notes: 1 Ground-truthing and functional assessments were conducted at wetlands where land access permission was available in 2012 and 2013.

2 A double dash indicates that those particular wetland classes were not ground-truthed in 2012 or 2013.

Traditional Ecological Knowledge

TEK information was not gathered during the wetland field surveys associated with the Black Pines to Hope Segment due the limited amount of field work that was conducted in this area as a result of lack of access to the Hope to Burnaby Segment.

The Hope to Burnaby Segment is located within: one ecozone (*i.e.*, Pacific Maritime) and three ecoregions of Canada (*i.e.*, Pacific Ranges, Cascade Ranges and Lower Mainland) (Agriculture and Agri-Food Canada 2013, Ecological Stratification Working Group 1995); one wetland region of Canada (*i.e.*, Pacific Temperate) (Government of Canada 1986); and one BGC zone of BC (*i.e.*, CWH) (BC MFLNRO 2012, Meidinger and Pojar 1991).

The Hope to Burnaby Segment does not cross any Migratory Bird Sanctuaries (Environment Canada 2013n), Western Hemisphere Shorebird Reserves (WHSRN 2013), IBAs (Bird Studies Canada and Nature Canada 2012) or Ramsar wetlands (Bureau of the Convention on Wetlands 2013).

The Hope to Burnaby Segment encounters the DUC Level 2 Priority Landscapes. The Level 2 Priority Landscapes consist of the BC Coastal Areas and Estuaries and the BC Interior (DUC 2013). One DUC conservation site was identified as being indirectly crossed by the proposed pipeline corridor, Cheam Lake Wetlands (Harrison pers. comm.). The proposed pipeline corridor does not cross the wetland, but does cross the southern portion of the regional park in which the conservation site is located.

The Hope to Burnaby Segment encounters the southwestern portion of the Cheam Lake Wetlands Regional Park in two locations (RK 1079.9 to RK 1080.0 and RK 1080.1 to RK 1080.4) and Surrey Bend Regional Park (RK 1160.5 to RK 1163.7).

Aboriginal Traditional Knowledge

The desktop review did not identify available ATK related to wetlands along the Hope to Burnaby Segment.

Consultation

Table 5.8-7 provides the outcomes of community workshops relating to presence and characteristics of wetland areas along the Hope to Burnaby Segment. The ESA workshops and meetings held with federal, provincial and municipal representatives did not reveal any site-specific wetland information. For more information on other topics raised during these workshops and meetings, see Section 3.0 of this volume and Section 2.0 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-7

SUMMARY OF COMMUNITY WORKSHOP OUTCOMES IN THE HOPE TO BURNABY SEGMENT

Workshop Location	Date	Outcome[1]
Hope, BC	June 11, 2013	During the Hope Community Workshop, participants commented that the Thacker Marsh is a valued wetland area near Kakawa Lake.
Chilliwack, BC	June 17, 2013	The participants at the Chilliwack Community Workshop identified the importance of the Cheam wetland.
Coquitlam, BC	June 25, 2013	The Coquitlam Community Workshop brought attention to the peaty soils and potential for subsidence and instability in the area after the Fraser River towards the Blue Mountain area.

Note: 1 Terminology captured at community workshops may be colloquial in nature and may not reflect wetland classification based on the Canadian Wetland Classification System (NWWG 1997).

Results of Field Data Collection

Helicopter reconnaissances along this segment were conducted from September 22 to 23, 2012 and on May 8, 2013. Ground-based field work at wetlands along this segment with available land access was conducted from April 28 to May 7 and June 10 to 12, 2013.

A desktop review of overflight photographs and satellite imagery was conducted to try and identify and delineate all potential wetland areas along the proposed pipeline corridor. The desktop review identified 55 wetlands (totalling approximately 4.8 km in length), comprising approximately 0.9% of the proposed pipeline corridor. Wetlands crossed by proposed pipeline corridor include 17 basin marshes, 12 riparian marshes, 2 hummock marshes, 5 flat swamps, 6 riparian swamps, 10 basin water and 3 riparian water.

The 2012 and 2013 wetland field surveys were conducted on lands where access was granted and confirmed that 6 wetlands are crossed by the proposed pipeline corridor. Wetlands crossed by the proposed pipeline corridor visited during the 2012 and 2013 ground-based wetland field surveys include one basin marsh, one riparian marsh, two hummock marshes, one basin water and one riparian water. Typical wetland community types documented include seasonal emergent, and deep marsh community types, open water community types, shrubby community types, and mixedwood treed community types. These numbers will be updated following the completion of the 2014 supplemental field program.

Wetland functional assessments were conducted at all wetlands ground-truthed in 2012 and 2013. The results of this assessment identified five wetlands were Low-Moderate Functional Condition and one wetlands were of Low Functional Condition.

It was also determined that two wetlands were associated with two rare ecological community found along the Hope to Burnaby Segment. These rare ecological communities are Blue-listed.

Table 5.8-8 provides a summary of the classes, length of disturbance and percent of proposed pipeline corridor crossed by wetlands along the proposed pipeline corridor in the Hope to Burnaby Segment. Additional information on wetlands along this segment is provided in Section 5.1 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-8

SUMMARY OF WETLANDS CROSSED ALONG THE HOPE TO BURNABY SEGMENT

Wetland Class	All Wetlands Crossed by Proposed Pipeline Corridor	Number of Ground-Truthed Wetlands Crossed by Proposed Pipeline Corridor[1]	Approximate Length of Wetland Crossed by Proposed Pipeline Corridor (m)	Percent of Proposed Pipeline Corridor Crossed
Basin Marsh	17	1	1,166	0.1
Riparian Marsh	12	1	1,087	0.1
Hummock Marsh	2	2	185	0.02
Flat Swamp	5	--[2]	529	0.1

TABLE 5.8-8 Cont'd

Wetland Class	All Wetlands Crossed by Proposed Pipeline Corridor	Number of Ground-Truthed Wetlands Crossed by Proposed Pipeline Corridor[1]	Approximate Length of Wetland Crossed by Proposed Pipeline Corridor (m)	Percent of Proposed Pipeline Corridor Crossed
Riparian Swamp	6	--[2]	752	0.1
Basin Water	10	1	653	0.1
Riparian Water	3	1	453	0.05
Total	55	6	4,824	0.5

Notes: 1 Ground-truthing and functional assessments were conducted at wetlands where land access permission was available in 2012 and 2013.

2 A double dash indicates that those particular wetland classes were not ground-truthed in 2012 or 2013.

Traditional Ecological Knowledge

TEK information was not gathered during the wetland field surveys associated with the Hope to Burnaby Segment due the limited amount of field work that was conducted in this area as a result of lack of access.

5.8.4 Burnaby to Westridge Segment

The Burnaby to Westridge Segment is located within one ecozone (*i.e.*, Pacific Maritime) and one ecoregion of Canada (*i.e.*, Lower Mainland) (Agriculture and Agri-Food Canada 2013, Ecological Stratification Working Group 1995); one wetland region of Canada (*i.e.*, Pacific Temperate) (Government of Canada 1986); and one BGC zone of BC (*i.e.*, CWH) (BC MFLNRO 2012, Meidinger and Pojar 1991).

The Burnaby to Westridge Segment does not cross any Migratory Bird Sanctuaries (Environment Canada 2013n), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Ramsar wetlands (Bureau of the Convention on Wetlands 2013).

One IBA, the English Bay and Burrard Inlet IBA (RK 3.2 to RK 3.6), is crossed by the Burnaby to Westridge Segment (Bird Studies Canada and Nature Canada 2012). This sheltered fjord of the Strait of Georgia incorporates a variety of habitats. This IBA was designated for three species of global importance including the western grebe, Barrow's goldeneye and surf scoter, and one species of national importance, the great blue heron. Historically, large numbers of western grebe wintered here, however, due to population decline these numbers have decreased so that often no more than approximately 1% of the global population have been observed. Counts of Barrow's goldeneye have also declined from approximately 4% of the global population utilizing the area in 1990 to about 1.5% in 2000. This IBA also supports on a regular basis at least 1% of the global surf scoter population. A known great blue heron nesting colony is also present within this IBA in the Stanley Park area. The great blue heron population located here has increased since 2001 resulting in approximately 1% of the Canadian population breeding in this area. The English Bay and Burrad Inlet IBA also supports other valuable bird species such a purple martin, pelagic and double-crested cormorants, osprey and bald eagles.

Within BC, the Burnaby to Westridge Segment encounters the DUC Level 2 Priority Landscapes. The Level 2 Priority Landscapes consist of the BC Coastal Areas and Estuaries and the BC Interior (DUC 2013). No DUC conservation sites are crossed by the proposed pipeline corridor (Harrison pers. comm.).

The Burnaby to Westridge Segment does not encounter any protected areas within the Wetland LSA.

Aboriginal Traditional Knowledge

The desktop review did not identify available ATK related to wetlands along the Burnaby to Westridge Segment.

Consultation

The ESA workshops, meetings held with federal, provincial and municipal representatives and community workshops did not provide any information on the presence and characteristics of wetland areas along the Burnaby to Westridge Segment. For more information on other topics raised during these workshops and meetings, see Section 3.0 of this volume and Section 2.0 of the Wetland Evaluation Technical Report Results of Volume 5C.

Field Data Collection

Helicopter reconnaissances along this segment were conducted from September 22 to 23, 2012 and on May 8, 2013. Ground-based field work was not conducted along the Burnaby to Westridge Segment due to lack of land access.

A desktop review of overflight photographs and satellite imagery was conducted to try and identify and delineate all potential wetland areas along the proposed pipeline corridor. The desktop review identified 1 wetland (totalling approximately 79.1 m in length), comprising approximately 0.01% of the proposed pipeline corridor. The wetland crossed by the proposed pipeline corridor is a basin marsh. This number will be updated following the completion of the 2014 supplemental field program.

This area was not ground-truthed in 2012 or 2013 due to the lack of land access. Potential wetland community types documented through the desktop review include seasonal emergent marsh community type.

As this area was not ground-truthed in 2012 or 2013, it is uncertain whether any wetlands associated with rare ecological communities are present.

Table 5.8-9 provides a summary of the classes, length of disturbance and percent of proposed pipeline corridor crossed by wetlands along the proposed pipeline corridor in the Burnaby to Westridge Segment. Additional information on wetlands along this segment, including conservation status, is provided in Section 5.1 of the Wetland Evaluation Technical Report of Volume 5C.

TABLE 5.8-9

SUMMARY OF WETLANDS CROSSED ALONG THE BURNABY TO WESTRIDGE SEGMENT

Wetland Class	All Wetlands Crossed by Proposed Pipeline Corridor	Number of Ground-Truthed Wetlands Crossed by Proposed Pipeline Corridor[1]	Approximate Length of Wetland Crossed by Proposed Pipeline Corridor (m)	Percent of Proposed Pipeline Corridor Crossed
Basin Marsh	1	--[2]	79	0.01
Total	1	--[2]	79	0.01

Notes: 1 Ground-truthing and functional assessments were conducted at wetlands where land access permission was available in 2012 and 2013.

2 A double dash indicates that those particular wetland classes were not ground-truthed in 2012 or 2013.

5.9 Vegetation

This subsection discusses the existing conditions of vegetation in the Vegetation RSA. The indicators selected for this element include vegetation communities of concern, plant species of concern (*i.e.*, vascular plants [those containing a vascular system for transporting fluids] and non-vascular plants [those without a vascular system, including bryophytes {mosses and liverworts}]), lichen species of concern and presence of infestations of provincially-listed weed species and other invasive non-native species identified as a concern. The rationale for the selection of indicators is provided in Section 7.2.9. The potential Project-related effects to vegetation arising from construction and operation of the proposed pipeline and mitigation pertaining to vegetation are discussed in Section 7.2.9. Refer to the Vegetation Technical Report of Volume 5C for additional details on the existing condition of vegetation resources.

This setting discusses the vegetative environment within the Vegetation RSA, which is the area where the direct and indirect influence of other land uses and activities could interact with Project-specific effects and may cause cumulative effects on vegetation. The Vegetation RSA consists of a 2 km wide band generally from the centre of the proposed pipeline corridor centre and facilities (*e.g.*, 1,000 m on both sides of the centre of the proposed pipeline corridor). The spatial boundaries of the Vegetation RSA are shown on Figures 5.9-1 to 5.9-4.

The vegetation surveys were comprised of rare vascular plant surveys, Terrestrial Ecosystem Mapping (TEM) field verification, a weed survey, a targeted survey for rare non-vascular plants and lichens as well as non-vascular collection. Where vegetation communities of concern were observed, the communities were mapped and photographed and their locations were recorded. All listed weeds and non-listed, non-native species were recorded at all locations where they were observed during the survey. Refer to the Vegetation Technical Report of Volume 5C for additional details on field survey methodology.

In order to determine pre-construction vegetation diversity, relative abundance and distribution of vegetation communities of ecological, economic or human importance, vegetation communities in the Vegetation RSA needed to be described using relevant and up-to-date ecological classification and mapping. Ecosite phase and site series variants were mapped for segments in Alberta and BC, respectively. There are no provincial guidelines for mapping ecological units in Alberta. Therefore, the provincial guidelines for mapping ecological units in BC were adopted for the portion of the proposed pipeline corridor in Alberta. In BC, the most relevant and up to date ecological classification system is outlined in the Field Manual for Describing Terrestrial Ecosystems Second Edition (BC Ministry of Forests and Range and BC MOE 2010) and various regional land management handbooks. See the Vegetation Technical Report of Volume 5C for more details on the field guides used in each natural subregion for the Project. Mapping methodology for the Project was developed according to the Standards for TEM in BC (Resources Inventory Committee 1998) and was applied to both the BC and Alberta portions of the Project.

In 2012 and 2013, TEK was gathered and recorded during the vegetation field surveys. During the field surveys, traditional methods of resource procurement were discussed, as well as modern methods currently employed. Seasonality of resource harvesting, species of traditional importance, identification of traditionally harvested plants, description of uses and preparation techniques as well as plant rarity and abundance was also important information shared by the Aboriginal participants. Geographical locations were identified, as were areas that are not used and the reasons why. Potential mitigation measures to reduce any Project-related effects on a resource were also discussed during the vegetation field surveys.

5.9.1 Overview

5.9.1.1 Edmonton to Hinton Segment

The Edmonton to Hinton Segment is located in five natural subregions within four natural regions in Alberta. This pipeline segment encounters the Central Parkland Natural Subregion within the Parkland Natural Region, the Dry Mixedwood and Central Mixedwood Natural Subregions within the Boreal Forest Natural Region, the Lower Foothills Natural Subregion within the Foothills Natural Region and the Montane Natural Subregion within the Rocky Mountain Natural Region (Natural Regions Committee 2006a).

The Central Parkland Natural Subregion occupies over 50,000 km² of land and most of these lands are under cultivation. Undulating till plains and hummocky uplands dominate the landscape. Plains rough fescue dominates the vegetation communities in the southern and eastern areas of the subregion with small trembling aspen-dominated communities occurring in more moist habitats. The northern and western parts of the subregion are composed of trembling aspen forest with grasslands restricted to the driest areas (Natural Regions Committee 2006a).

The Dry Mixedwood Natural Subregion is the most southern and the warmest of the Boreal Forest Subregions in Alberta. Trembling aspen forests with understories dominated by prickly rose, low-bush cranberry, beaked hazelnut and Canada buffaloberry are typical of the uplands. Treed, shrubby or sedge-dominated fens are common in wet areas. Jack pine typically dominates dry, well-drained areas (Natural Regions Committee 2006a).

The Central Mixedwood Natural Subregion is the largest natural subregion in Alberta and is characterized by upland forests and wetlands on level to gently undulating plains. Upland forests are a mosaic of trembling aspen, mixedwood and white spruce. Jack pine stands occur on coarser materials. Wetlands are often extensive and are dominated by black spruce fens and bogs (Natural Regions Committee 2006a).

Natural landscapes in the Lower Foothills Natural Subregion are characterized by rolling, till-covered plateaus forested by mesic, closed canopy mixed stands of trembling aspen, lodgepole pine, white spruce and balsam poplar (Natural Regions Committee 2006a).

Vegetation communities in the Montane Natural Subregion are mainly comprised of closed forest communities dominated by lodgepole pine, Douglas-fir, trembling aspen and white spruce. Deciduous forests occur on fluvial fans, terraces and flood plains. Open grasslands occur on dry and exposed sites, and are dominated by various grasses including June grass, northern wheatgrass, western wheatgrass, Kentucky bluegrass and slender wheatgrass (Natural Regions Committee 2006a).

The Edmonton to Hinton Segment is located within five provincial Environmentally Significant Areas (70, 99, 441, 442 and 690) (Fiera Biological Consulting Ltd. 2009). ATPR defines Environmentally Significant Areas as being important to the long-term maintenance of biological diversity, soil, water or other natural processes, at multiple spatial scales and/or areas that contain rare or unique elements or that include elements that may require special management consideration due to their conservation needs. However, ATPR states that Environmentally Significant Areas do not represent government policy and do not necessarily require legal protection. They are intended to be an information tool to help inform land use planning and policy at local, regional and provincial scales. Further details regarding these Environmentally Significant Areas are provided in the Vegetation Technical Report of Volume 5C.

There were six protected areas identified within the Vegetation RSA along the Edmonton to Hinton Segment: Strathcona Science Provincial Park; Wabamun Lake Provincial Park; Nojack Provincial Recreation Area; Yates Natural Area; Hornbeck Creek Provincial Recreation Area; and Obed Lake Provincial Park (ATPR 2012, NRCan 2013b). A summary of vegetation communities traversed by this segment is detailed in the TEM Report in Appendix C of the Vegetation Technical Report of Volume 5C.

Land use along the Edmonton to Hinton Segment is a mix of native land use (49% of the length of the segment) and agricultural and anthropogenic (*e.g.*, recreational, cleared or disturbed) (44% of the length of the segment). The dominant native vegetation land use traversed by the route is treed (46%) with some treed pasture (3%). The dominant agricultural land uses are hay (20%), cultivation (12%) and tame pasture (10%). Approximately 7% of this segment was not surveyed for land use, some of which was due to access issues. The Project parallels existing disturbance for approximately 92% of the length in this segment. Land use and length of new cut for this segment are further discussed in Section 5.0 of Volume 5B.

Vegetation surveys in this segment were conducted from May 17 to 28 (TEM), June 7 to 13 and 18 to 29 (early-season), July 16 to 22 and August 3 to 14, 2013 (late-season).

5.9.1.2 Hargreaves to Darfield Segment

The Hargreaves to Darfield Segment is located within three BGC zones. The first zone, the ICH Zone, has the highest diversity of tree species of any zone in BC. Western redcedar and western hemlock dominate mature climax forests, while lodgepole pine, trembling aspen and paper birch are common in all areas. Wetlands are infrequent due to the mountainous terrain throughout most of the zone. Where they do occur, wetlands are usually small transitional bogs, fens and skunk cabbage swamps. Riparian and lakeshore marshes tend to be more common (Meidinger and Pojar 1991). The proposed pipeline corridor crosses five subzones in the ICH BGC Zone: Moist Mild (mm); Wells Gray Wet Cool (wk1); Mica Very Wet Cool (vk1); Thompson Moist Warm (mw3); and North Thompson Dry Warm (dw3).

The SBS BGC Zone dominates the central interior of BC. The climate in this zone is one of extremes; the winter is severe and snowy, and the summers are relatively warm and moist. However, the winters are slightly shorter and the growing season is slightly longer than those of other boreal zones. The zone is characterized by upland coniferous forests of subalpine fir and hybrid white spruce. Major streams and rivers are bordered by alluvial forests that are dominated by black cottonwood with an occasional spruce. Wetlands are common and include sedge marshes, shrub and tree dominated fens, treed swamps and bogs (Meidinger and Pojar 1991). The proposed pipeline corridor crosses one subzone in the SBS BGC Zone, the McLennan Dry Hot (dh1).

The landscape of the IDF BGC Zone consists largely of open to closed, mature forests of Douglas-fir. Pure Douglas-fir climax stands are common. Mixed stands of Douglas-fir and lodgepole pine are often present in areas frequently affected by fire. Extensive grassland communities also occur in parts of the zone due to a combination of edaphic and topographic conditions and fire history. Non-forested wetlands are common in this zone and include marshes, sedge and shrub fens, shrub-carrs and saline meadows. Willow swamps often occur along small streams and drainages (Meidinger and Pojar 1991). The proposed pipeline corridor crosses seven subzones in the IDF BGC Zone: the Thompson Moist Warm (mw2); the Thompson Moist Warm – Steep South phase (mw2b); the Thompson Very Dry Hot (xh2); the Thompson Very Dry Hot – Grassland phase (xh2a); the Okanagan Very Dry Hot (xh1); the Thompson Dry Cool (dk1); and the Cascade Dry Cool (dk2).

There were 12 protected areas identified within the Vegetation RSA along the Hargreaves to Darfield Segment. The proposed pipeline corridor crosses two of these: Finn Creek Provincial Park from RK 638.7 to RK 639.3; and North Thompson River Provincial Park from RK 725.5 to RK 725.9 (BC MFLNRO 2008b,c, NRCan 2013b). The other 10 protected areas located within the Vegetation RSA, but not crossed by the corridor, include Mount Robson Provincial Park, Rearguard Falls Provincial Park, Jackman Flats Provincial Park, Pyramid Creek Falls Provincial Park, Blue River Black Spruce Provincial Park, Blue River Pine Provincial Park, Wire Cache Provincial Park, Eakin Creek Canyon Provincial Park, North Thompson Islands Provincial Park and Chu Chua Cottonwood Provincial Park (BC MFLNRO 2008b,c, NRCan 2013b). Within the Vegetation RSA, this segment encounters 169 legal Old Growth Management Areas (OGMAs) and 40 non-legal OGMAs (BC MFLNRO 2009a,b). Of these OGMAs, 32 legal and 7 non-legal OGMAs are crossed by the proposed pipeline corridor. A summary of vegetation communities traversed by this segment of the Project is detailed in the TEM Report in Appendix C of the Vegetation Technical Report of Volume 5C.

The Hargreaves to Darfield Segment is dominated by native vegetation and the predominant native vegetation type is treed (85% of the length of the segment) with some treed pasture (1%). The dominant agricultural land uses are tame pasture (7%) and hay (4%), with some anthropogenic land use (*e.g.*, recreational, disturbed). Less than 1% of this segment was not surveyed for land use due to access issues. The Project parallels existing disturbance for approximately 88% of the length in this segment. Land use and length of new cut for this segment are further discussed in Section 5.0 of Volume 5B.

Vegetation surveys were conducted from May 6 to 13 (TEM), June 17 to 30 (early-season) and August 1 to 14, 2013 (late-season).

5.9.1.3 Black Pines to Hope Segment

The Black Pines to Hope Segment crosses seven different BGC zones. One zone, the IDF BGC Zone, is described above in Section 5.9.1.2 and the other six zones are described below.

The PP BGC Zone is the driest and has the warmest summer temperatures of all the forested zones in BC. The forests in this zone are dominated by very open PP stands with an understory consisting largely of bluebunch wheatgrass. Grasslands are commonly scattered throughout the zone. Fires have played an important role in the ecology of the zone. Alkaline ponds can occur in depressional areas (Meidinger and Pojar 1991). The proposed pipeline corridor crosses one Subzone in the PP BGC Zone, the Thompson Very Dry Hot (xh2).

The BG BGC Zone is an arid zone largely characterized by grasslands dominated by BGs, such as bluebunch wheatgrass, and shrubs, such as big sagebrush, are also present. The vegetation reflects minor changes in topography, aspect and drainage. Patterns of native plant communities are poorly understood because of heavy livestock grazing throughout the zone, which has lead to an increased abundance of unpalatable or weedy vascular species. Small patches of trembling aspen can occur on wetter areas at higher elevations. Wetlands are common throughout the zone and include shrub dominated habitats, marshes with shallow open water and saline meadows (Meidinger and Pojar 1991). The proposed pipeline corridor crosses two subzones in the BG BGC Zone, the Nicola Very Dry Warm (xw1) and the Thompson Very Dry Hot (xh2).

The MS BGC Zone is characterized by climax stands of hybrid white spruce and subalpine fir. Extensive, young and maturing seral stands of lodgepole pine are common in areas following wildfires. Trembling aspen occurs throughout the zone. Wetland areas are uncommon due to mountainous topography, but where they do occur they are usually shrub fens (Meidinger and Pojar 1991). The proposed pipeline corridor crosses two Subzones in the MS BGC Zone, the South Thompson Dry Mild (dm2) and the Cascade Moist Warm (mw1).

The CWH is, on average, the wettest BGC zone in BC. Western hemlock is the most common tree species in forested areas. Western redcedar occurs throughout the zone and Douglas-fir is abundant in drier areas of the zone. Shore pine is common on very dry or very boggy areas throughout the zone. Sitka spruce occurs over a wide variety of habitats north of Vancouver Island but is restricted to flood plains and exposed beaches in the south (Meidinger and Pojar 1991). The proposed pipeline corridor crosses four subzones in the CWH BGC Zone: the Southern Moist Submaritime (ms1); the Southern Dry Submaritime (ds1); the Dry Maritime (dm); and the Eastern Very Dry Maritime (xm1).

The ESSF BGC Zone is the uppermost (highest elevation) zone in southern interior BC and is characterized by mountainous terrain. The climate is generally cool with a short growing season and a long winter. As a result, most of the precipitation (50-70%) is in the form of snow. Engelmann spruce and subalpine fir are the dominant climax tree species. Engelmann spruce typically dominates the canopy of mature stands with subalpine fir being more common in the understory. In drier areas or areas affected by fire, lodgepole pine may be dominant (Meidinger and Pojar 1991). The proposed pipeline corridor crosses one subzone in the ESSF BGC Zone, the Moist Warm (mw).

The MH BGC Zone occurs at relatively high elevations (400-1,000 m) and is characterized by short, cool summers and long, cool, wet winters, with heavy snow cover for several months (Meidinger and Pojar 1991). The most common tree species in the zone are MH, amabilis fir and yellow-cedar, although they do not grow in continuous stands and are largely confined to lower elevations. Other characteristics of the MH BGC Zone are the high occurrence of shrubs such as blueberries and copperbush, the relatively low occurrence of herbs and the dominance of bryophytes (Meidinger and Pojar 1991). The proposed pipeline corridor crosses one subzone in the MH BGC Zone, the Leeward Moist Maritime (mm2).

The Black Pines to Hope Segment encounters seven protected areas within the Vegetation RSA. The proposed pipeline corridor crosses two of these, the Lac du Bois Grasslands Protected Area from RK 829.0 to RK 836.8 and RK 842.4 to RK 843.9, as well as the Coquihalla Summit Recreation Area from

RK 992.5 to RK 1005.1 (BC MFLNRO 2008b,c, NRCan 2013b). The other five protected areas located within the Vegetation RSA are North Thompson Oxbows Jensen Island Provincial Park, McQueen Creek Ecological Reserve, Coldwater River Provincial Park, Coquihalla River Provincial Park and Coquihalla Canyon Provincial Park (BC MFLNRO 2008b,c, NRCan 2013b). Within the Vegetation RSA, this segment encounters 33 legal OGMAs and 67 non-legal OGMAs (BC MFLNRO 2009a,b). There are 9 legal OGMAs and 19 non-legal OGMAs crossed by the proposed pipeline corridor. A summary of vegetation communities traversed by this segment is detailed in the TEM Report in Appendix C of the Vegetation Technical Report of Volume 5C.

The Black Pines to Hope Segment is dominated by native vegetation (70% of the length of the segment) and the predominant native vegetation type is treed (54%) with some native grassland (9%) and some treed pasture (7%). The dominant agricultural land uses are tame pasture (10%) and hay (2%), with anthropogenic land use (*e.g.*, disturbed) making up 4%. Approximately 13% of this segment was not surveyed for land use due to access issues. The Project parallels existing disturbance for approximately 86% of the length in this segment. Land use and length of new cut for this segment are further discussed in Section 5.0 of Volume 5B.

Vegetation surveys in this segment were conducted from June 3 to 9 (TEM), May 23 to June 3 (early-season), July 15 to 25 and August 26 to 29, 2013 (late-season).

5.9.1.4 Hope to Burnaby Segment

The Hope to Burnaby Segment crosses only one BGC zone, the CWH BGC Zone in BC, which was described above in Section 5.9.1.3.

The Hope to Burnaby Segment encounters four protected areas within the Vegetation RSA. The proposed pipeline corridor crosses three of these, F.H. Barber Provincial Park from RK 1062.8 to RK 1062.8, Cheam Lake Wetlands Regional Park from RK 1079.9 to RK 1080.0 and from RK 1080.1 to RK 1080.4 as well as Surrey Bend Regional Park from RK 1160.5 to RK 1163.7 (BC MFLNRO 2008b,c, NRCan 2013b). The other protected area within the Vegetation RSA is Bridal Veil Falls Provincial Park. Within the Vegetation RSA, this segment encounters seven legal OGMAs and does not encounter any non-legal OGMAs (BC MFLNRO 2009a,b). One legal OGMA is crossed by the proposed pipeline corridor. The proposed pipeline corridor does not cross any non-legal OGMAs. A summary of vegetation communities traversed by this segment of the Project is detailed in the TEM Report in Appendix C of the Vegetation Technical Report of Volume 5C.

Land use along the Hope to Burnaby Segment is predominantly native land use (52% of the length of the segment) with anthropogenic land use making up 36% of the length of the proposed pipeline corridor. Native land use is composed of treed areas (51%) and some treed pasture (1%). The dominant agricultural land uses are cultivation (11%), tame pasture (4%) and hay (4%), with anthropogenic land use (*e.g.*, recreational, disturbed land [*e.g.*, residential, roads, greenhouses, farm yards, blueberry cultivation]) making up 15% of the length of the segment. Approximately 12% of this segment was not surveyed for land use, primarily due to access issues. The Project parallels existing disturbance for approximately 99% of the length in this segment. Land use and length of new cut for this segment are further discussed in Section 5.0 of Volume 5B.

Vegetation surveys in this segment were conducted from April 11 to 19 (TEM), May 7 to 10 and May 22 to 23 (early-season), and July 13 to 15 and August 19 to 23, 2013 (late-season).

5.9.1.5 Burnaby to Westridge Segment

The Burnaby to Westridge Segment crosses only one BGC zone, the CWH BGC Zone in BC, which is described above in Section 5.9.1.3.

The Burnaby to Westridge Segment does not encounter any protected areas within the Vegetation RSA (BC MFLNRO 2008b,c, NRCan 2013b). This segment does not encounter any legal or non-legal OGMAs (BC MFLNRO 2009a,b). A summary of vegetation communities traversed by this segment of the Project is detailed in the TEM Report in Appendix C of the Vegetation Technical Report of Volume 5C.

Land use and length of new cut for this segment are further discussed in Section 5.0 of Volume 5B. Due to lack of land access in 2013, vegetation surveys were not conducted on the Burnaby to Westridge Segment of the proposed pipeline corridor. Vegetation surveys on this segment are expected to be conducted in 2014.

5.9.2 Vegetation Communities of Concern

The vegetation communities of concern indicator addresses rare ecological communities as identified by the Alberta Conservation Information Management System (ACIMS), the BC Identified Wildlife Management Strategy (IWMS) and the BC CDC, as well as the vegetation communities identified as the most impacted by the Project (as determined through TEM). In addition, this indicator addresses vegetation communities identified as of concern during consultation, specifically grassland communities within the BG BGC Zone. This indicator addresses the NEB *Filing Manual* requirement to consider avoidance of sensitive or rare communities. Potential rare ecological community locations along the proposed pipeline corridor are identified on Figure 2 in the Vegetation Technical Report of Volume 5C and shown on the Environmental Alignment Sheets of Volume 6E.

5.9.2.1 Edmonton to Hinton Segment

Vegetation surveys were conducted along those locations of the Edmonton to Hinton Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support vegetation communities of concern. The survey methodology used and complete results of the 2013 vegetation surveys are provided in the Vegetation Technical Report of Volume 5C. A list of rare communities that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

A search of the ACIMS database identified no previously recorded occurrences of rare ecological communities within the Vegetation RSA in this segment (ACIMS 2013). See the Vegetation Technical Report of Volume 5C for more details. Five potentially rare ACIMS-listed ecological communities were observed during the 2013 vegetation surveys (see Table 5.9-1).

TABLE 5.9-1

VEGETATION COMMUNITIES OF CONCERN OBSERVED ALONG THE EDMONTON TO HINTON SEGMENT

Common Name	Scientific Name	Provincial Rank[1]	Observed Number of Occurrences
beaked sedge marsh[2]	*Carex rostrata* marsh (needs confirmation)	S3?	1
beaked willow - red osier dogwood community	*Salix bebbiana - Cornus stolonifera* community	S3?	1
white birch – stiff club-moss community	*Betula papyrifera – Lycopodium annotinum* community	S2?	3

Notes: 1 Provincial (S) ratings range from S1 (five or fewer occurrences or very few remaining hectares) to S5 (demonstrably secure, though it may be quite rare in parts of its range, especially at the periphery). Ranks may be combined (*e.g.*, S1S2). This indicates a larger margin of error than ranks assigned a "?" qualifier. Ratings that are not of concern (4-5) are not included.

S1 = Critically Imperilled: because of extreme rarity or because of some factor(s) making it especially vulnerable to extirpation. Typically five or fewer occurrences or very few remaining individuals (< 1,000).

S2 = Imperilled: because of rarity or because of some factor(s) making it very vulnerable to extirpation. Typically 6-20 occurrences or few remaining individuals (1,000-3,000).

S3 = Vulnerable: because rare and uncommon, or found in a restricted range (even if abundant at some locations), or because of other factors making it vulnerable to extirpation. Typically 21-100 occurrences or between 3,000 and 10,000 individuals.

S#? = Inexact numeric rank: denotes inexact numeric rank.

? = Element is not yet ranked (*i.e.*, S?), or has an inexact numerical rank (*e.g.*, S3?).

2 Potentially observed community. The non-vascular species collected require confirmation before community can be confirmed.

Communities most affected were selected as those ecosites in Alberta with more than 2.75% of the total ecosite located on the Footprint, based on the distribution of values between 0.5% and 6.4%. The total area of the ecosites within the Vegetation RSA may not be large; most of the ecosites occupy less than 100 ha of the Vegetation RSA, while the Vegetation RSA in Alberta occupies approximately 50,000 ha.

However, these ecosites are disproportionately located along the Footprint (more than 2.75% of their total area within the Vegetation RSA is located along the Footprint), meaning that these ecosites will be more affected by the Project than other ecosites within the Vegetation RSA.

The most affected communities in Alberta are ecosites varying from nutrient poor to medium with acidic soil conditions, dominated by lodgepole pine, black spruce, common Labrador tea, bog cranberry and common blueberry (Labrador tea-mesic), to alkaline nutrient rich fens characterized by Tamarack, dwarf birch or willow and sedges. The ecosite most affected by the Project is a marsh ecosite found along shorelines of water bodies and riparian zones. The most affected communities in Alberta are discussed in detail in Section 7.2.9.6.

5.9.2.2 Hargreaves to Darfield Segment

Vegetation surveys were conducted along those locations of the Hargreaves to Darfield Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support vegetation communities of concern. The survey methodology used and the complete results of the summer 2013 vegetation surveys are provided in the Vegetation Technical Report of Volume 5C. A list of rare communities that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

A search of the BC CDC identified one rare ecological community within the Vegetation RSA in this segment (BC CDC 2013b). The previously observed rare ecological community is a lodgepole pine - velvet-leaved blueberry – *Cladonia* lichens community (ranked S2S3, Blue). See the Vegetation Technical Report of Volume 5C for more details. There were 25 potentially rare, Blue-listed BC CDC-listed ecological communities either observed during the 2013 vegetation surveys or identified using TEM (see Table 5.9-2).

TABLE 5.9-2

**VEGETATION COMMUNITIES OF CONCERN
OBSERVED ALONG THE HARGREAVES TO DARFIELD SEGMENT**

Common Name	Scientific Name	Provincial Rank[1]	Provincial Listing[2]	Observed Number of Occurrences
Bebb's willow/bluejoint reedgrass community	*Salix bebbiana/Calamagrostis canadensis* community	S3	Blue	4
common cattail marsh	*Typha latifolia* marsh	S3	Blue	7
hard-stemmed bulrush deep marsh	*Schoenoplectus acutus* deep marsh	S3	Blue	1
lodgepole pine - velvet-leaved blueberry – *Cladonia* lichens community	*Pinus contorta - Vaccinium myrtillus – Cladonia* spp. community	S2S3	Blue	7
scrub birch/water sedge community	*Betula nana/Carex aquatilis* community	S3	Blue	1
Sitka willow – Pacific willow/skunk cabbage community	*Salix sitchensis – Salix lasiandra* var. *Lasiandra/Lysichiton americanus* community	S2	Red	1
swamp horsetail – beaked sedge community	*Equisetum fluviatile – Carex utriculata* community	S3	Blue	3
western redcedar – paper birch/oak fern community	*Thuja plicata – Betula/Gymnocarpium dryopteris* community	S3?	Blue	1

Notes: 1 Provincial (S) ratings range from S1 (five or fewer occurrences or very few remaining hectares) to S5 (demonstrably secure, though it may be quite rare in parts of its range, especially at the periphery). Ranks may be combined (*e.g.*, S1S2). This indicates a larger margin of error than ranks assigned a "?" qualifier. Ratings that are not of concern (4-5) are not included.

S2 = Imperilled: because of rarity or because of some factor(s) making it very vulnerable to extirpation. Typically 6-20 occurrences or few remaining individuals (1,000-3,000).

S3 = Vulnerable: because rare and uncommon, or found in a restricted range (even if abundant at some locations), or because of other factors making it vulnerable to extirpation. Typically 21-100 occurrences or between 3,000 and 10,000 individuals.

S#S# = Range Rank: a numeric range rank (*e.g.*, S2S3) is used to indicate the range of uncertainty about the exact status of the element.

S#? = Inexact numeric rank: denotes inexact numeric rank.

? = Element is not yet ranked (*i.e.*, S?), or has an inexact numerical rank (*e.g.*, S3?).

2 Red-listed refers to a species that is Extirpated, Endangered or Threatened in BC. Blue-listed refers to a species of Special Concern (formerly vulnerable) in BC.

Communities most affected were selected as those BGC subzone variants in BC whose total area (ha) on the Footprint, when compared to the BGC subzone variant total area (ha) in the Vegetation RSA, is more than 2.75% of the total community. Communities most affected were selected as those with more than 2.75% of the total community located on the Footprint, based on the distribution of values between 0.05% and 3.75%. These BGC subzone variants are disproportionately located along the Footprint (more than 2.75% of their total area within the Vegetation RSA is located along the Footprint), meaning that these variants will be more affected by the Project than other variants within the Vegetation RSA.

The most affected communities in BC are the McLennan Dry Hot Sub Boreal Spruce (SBSdh1) variant, the Cascade Moist Warm MS (Msmw1) variant and the Moist Warm ESSF (ESSFmw) variant. The McLennan Dry Hot Sub Boreal Spruce community only occurs along the Hargreaves to Darfield Segment. This community is characterized by seral stands of lodgepole pine, hydrid white spruce and Douglas-fir with thimbleberry, birch-leaved spirea, black huckleberry and falsebox common in the understory (Lloyd *et al.* 2005). The most affected communities in BC are discussed in detail in Section 7.2.9.6.

5.9.2.3 Black Pines to Hope Segment

Vegetation surveys were conducted along those locations of the Black Pines to Hope Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support vegetation communities of concern. The survey methodology used and the complete results of the 2013 vegetation surveys are provided in the Vegetation Technical Report of Volume 5C. A list of rare communities that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

During consultation, grassland communities within the BG BGC Zone in the Kamloops region were also identified as communities of concern. The proposed pipeline corridor intersects the BG BGC Zone at a few locations in the Black Pines to Hope Segment, while avoiding it for most of the pipeline length. The BG BGC Zone is intersected for a total of approximately 35 km. A search of the BC CDC identified no previously observed rare ecological communities within the Vegetation RSA in this segment (BC CDC 2013b). Fifteen potentially rare (Red and Blue-listed) BC CDC-listed ecological communities were either observed during the 2013 vegetation surveys or identified using TEM (see Table 5.9-3). One of these communities, the western redcedar – Sitka spruce/skunk cabbage community, is listed under the BC IWMS.

TABLE 5.9-3

VEGETATION COMMUNITIES OF CONCERN IN THE BLACK PINES TO HOPE SEGMENT

Common Name	Scientific Name	Provincial Rank[1]	Provincial Listing[2]	Observed Number of Occurrences
amabilis fir – western redcedar/devil's club moist submaritime community	*Abies amabilis – Thuja plicata/Oplopanax horridus* moist submaritime community	S3	Blue	2
big sagebrush/bluebunch wheatgrass community	*Artemisia tridentata/Pseudoregneria spicata* community	S2	Red	2
common cattail marsh	*Typha latifolia* marsh	S3	Blue	1
Douglas-fir/common snowberry – Saskatoon community	*Pseudotsuga menziesii/Symphoricarpus albus – Amelanchier alnifolia* community	S2	Red	2
Douglas-fir – ponderosa pine/pinegrass community	*Pseudotsuga menziesii/Pinus ponderosa/Calamagrostis rubescens* community	S3	Blue	2
Douglas-fir – ponderosa pine/snowbrush community	*Pseudotsuga menziesii/Pinus ponderosa/Ceanothus velutinus* community	S3	Blue	1
hybrid white spruce – Douglas-fir – subalpine fir community[3]	*Picea engelmannii x glauca – Pseudotsuga menziesii – Abies lasiocarpa* community	Unknown – unique community	Unknown	1
narrow-leaf willow shrubland	*Salix exigua* shrubland	S2	Red	3
western redcedar – Douglas-fir/vine maple community	*Thuja picata – Pseudotsuga menziesii/Acer circinatum* community	S2S3	Blue	1

TABLE 5.9-3 Cont'd

Notes: 1 Provincial (S) ratings range from S1 (five or fewer occurrences or very few remaining hectares) to S5 (demonstrably secure, though it may be quite rare in parts of its range, especially at the periphery). Ranks may be combined (*e.g.*, S1S2). This indicates a larger margin of error than ranks assigned a "?" qualifier. Ratings that are not of concern (4-5) are not included.

S2 = Imperilled: because of rarity or because of some factor(s) making it very vulnerable to extirpation. Typically 6-20 occurrences or few remaining individuals (1,000-3,000).

S3 = Vulnerable: because rare and uncommon, or found in a restricted range (even if abundant at some locations), or because of other factors making it vulnerable to extirpation. Typically 21-100 occurrences or between 3,000 and 10,000 individuals.

2 Red-listed refers to a species that is Extirpated, Endangered or Threatened in BC. Blue-listed refers to a species of Special Concern in BC.

3 Potentially observed community. The species collected and description require confirmation before the community can be confirmed.

The most affected communities in BC are the McLennan Dry Hot Sub Boreal Spruce (SBSdh1) variant, the Cascade Moist Warm MS (Msmw1) variant and the Moist Warm ESSF (ESSFmw) variant. The Cascade Moist Warm MS variant and the Moist Warm ESSF variant occur only along the Black Pines to Hope Segment. The Cascade variant is characterized by seral stands of lodgepole pine, hydrid white spruce and subalpine fir with thimbleberry, birch-leaved spirea, black huckleberry and falsebox common in the understory. The ESSFmw variant is dominated by Englemann spruce and ambilis with white-flowered rhododendron, sitka valerian and black huckleberry common in the understory (Lloyd *et al*. 1990). The most affected communities in BC are discussed in detail in Section 7.2.9.6.

5.9.2.4 Hope to Burnaby Segment

Vegetation surveys were conducted along those locations of the Hope to Burnaby Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support vegetation communities of concern. The survey methodology used and the complete results of the summer 2012 and summer 2013 vegetation assessments are provided in the Vegetation Technical Report of Volume 5C. A list of rare communities that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

A search of the BC CDC identified no previously observed rare ecological communities within the Vegetation RSA in this segment (BC CDC 2013b). There were nine potentially rare, Blue-listed BC CDC-listed ecological communities either observed during the 2013 vegetation surveys or identified using TEM (see Table 5.9-4). One of these communities, the western redcedar – Sitka spruce/skunk cabbage community, is listed under the BC IWMS.

TABLE 5.9-4

VEGETATION COMMUNITIES OF CONCERN IN THE HOPE TO BURNABY SEGMENT

Common Name	Scientific Name	Provincial Rank[1]	Provincial Listing[2]	Observed Number of Occurrences
black cottonwood - red alder/salmonberry community	*Populus trichocarpa - Alnus rubra/Rubus spectabilis* community	S3	Blue	2
common cattail marsh	*Typha latifolia* marsh	S3	Blue	2
hard-stemmed bulrush deep marsh	*Schoenoplectus acutus* deep marsh	S3	Blue	1
western redcedar – Douglas-fir/vine maple community	*Thuja picata – Pseudotsuga menziesii/Acer circinatum* community	S2S3	Blue	1
western redcedar - Sitka spruce/skunk cabbage community	*Thuja plicata - Picea sitchensis/Lysichiton americanus* community	S3?	Blue	1
western redcedar/sword fern very dry maritime community	*Thuja plicata – Polystichum munitum* very dry maritime community	S2S3	Blue	2

TABLE 5.9-4 Cont'd

Notes: 1 Provincial (S) ratings range from S1 (five or fewer occurrences or very few remaining hectares) to S5 (demonstrably secure, though it may be quite rare in parts of its range, especially at the periphery). Ranks may be combined (*e.g.*, S1S2). This indicates a larger margin of error than ranks assigned a "?" qualifier. Ratings that are not of concern (4-5) are not included.

S3 = Vulnerable: because rare and uncommon, or found in a restricted range (even if abundant at some locations), or because of other factors making it vulnerable to extirpation. Typically 21-100 occurrences or between 3,000 and 10,000 individuals.

S#? = Inexact numeric rank: denotes inexact numeric rank.

? = Element is not yet ranked (*i.e.*, S?), or has an inexact numerical rank (*e.g.*, S3?).

2 Red-listed refers to a species that is Extirpated, Endangered or Threatened in BC. Blue-listed refers to a species of Special Concern in BC.

The most affected communities in BC are the Cascade, McLennan and Moist Warm ESSF (ESSFmw) variants, none of which occur along the Hope to Burnaby Segment.

5.9.2.5 Burnaby to Westridge Segment

A list of rare communities that have the potential to occur within the Vegetation RSA of the Burnaby to Westridge Segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

A search of the BC CDC identified no previously observed rare ecological communities within the Vegetation RSA in this segment (BC CDC 2013b).

Due to lack of land access in 2013, vegetation surveys were not conducted on the Burnaby to Westridge Segment. Vegetation surveys on this segment are planned in 2014.

5.9.3 Plant and Lichen Species of Concern

The plant and lichen species of concern indicator addresses rare plant and lichen species as identified by *SARA*, COSEWIC, the Alberta *Wildlife Act* and *Wildlife Regulation*, ACIMS, the BC IWMS and the BC CDC. This indicator addresses the NEB *Filing Manual* requirement to determine effects related to plant species at risk or of special status. Rare plant and rare lichen locations along the proposed pipeline segments are identified on Figure 2 in the Vegetation Technical Report of Volume 5C and shown on the Environmental Alignment Sheets of Volume 6E.

5.9.3.1 Edmonton to Hinton Segment

Vegetation surveys were conducted along those locations of the Edmonton to Hinton Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support rare plants and lichens. The survey methodology used and the complete results of the 2013 vegetation surveys are provided in the Vegetation Technical Report of Volume 5C. A list of rare plants and lichens that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

A search of the ACIMS database identified 38 occurrences of rare plant and lichen species within the Vegetation RSA in this segment (ACIMS 2013). There are 14 vascular plant species, 13 moss species, 2 liverwort species and 9 lichen species. None of the previously observed species are plants or lichens listed under COSEWIC, *SARA* or the Alberta *Wildlife Act* and *Wildlife Regulation*. See the Vegetation Technical Report of Volume 5C for more detail.

No COSEWIC or *SARA*-listed species were observed during the 2013 vegetation survey of this pipeline segment. In addition, no species designated under the Alberta *Wildlife Act* were observed. A total of 53 ACIMS-listed plant or lichen species were observed during the 2013 vegetation survey of this segment (see Table 5.9-5).

TABLE 5.9-5

PLANT AND LICHEN SPECIES OF CONCERN OBSERVED ALONG THE EDMONTON TO HINTON SEGMENT

Common Name	Scientific Name	Type	Provincial Rank[1]	Observed Number of Occurrences
Anastrophyllum liverwort	*Anastrophyllum helleranum*	liverwort	S2	3
Atrichum moss	*Atrichum selwynii*	moss	S2	1
Blasia liverwort	*Blasia pusilla*	liverwort	S1	1
capitate sedge	*Carex capitata*	vascular plant	S3 (W)	3
Cladonia lichen	*Cladonia humilis*	lichen	S1	1
dragon Cladonia lichen	*Cladonia squamosa*	lichen	S2	1
droplet notchwort	*Lophozia guttulata*	liverwort	S2	1
golden saxifrage	*Chrysosplenium iowense*	vascular plant	S3?	9
goldthread	*Coptis trifolia*	vascular plant	S3	2
linear-leaved pondweed	*Potamogeton strictifolius*	vascular plant	S2	1
meadow bitter cress	*Cardamine pratensis*	vascular plant	S3	1
Pellia species[2]	*Pellia* sp.	liverwort	Unknown	2
Physciella lichen	*Physciella chloantha*	lichen	Not listed	1
prairie wedge grass	*Sphenopholis obtusata*	vascular plant	S2	7
Ricardia liverwort	*Riccardia latifrons*	liverwort	S2	1
rush species[2]	*Juncus* sp.	vascular plant	Unknown	1
Sarmenthypnum moss	*Sarmenthypnum sarmentosum*	moss	S2	1
saxfridge species[2]	*Chrysosplenium* sp.	vascular plant	Unknown	4
scalloped grape fern	*Botrychium crenulatum*	vascular plant	S1	1
Schistidium moss	*Schistidium confertum*	moss	SNR	1
short-tail rush	*Juncus brevicaudatus*	vascular plant	S2	1
slender naiad	*Najas flexilis*	vascular plant	S2	1
snakeskin liverwort	*Conocephalum salebrosum*	liverwort	S2	5
spatulate grape fern	*Botrychium spathulatum*	vascular plant	S2	1
tall blue lettuce	*Lactuca biennis*	vascular plant	S2	1
western oak fern	*Gymnocarpium disjunctum*	vascular plant	S1	1

Notes: 1 Provincial (S) ratings range from S1 (five or fewer occurrences or very few remaining hectares) to S5 (demonstrably secure, though it may be quite rare in parts of its range, especially at the periphery). Ranks may be combined (*e.g.*, S1S2). This indicates a larger margin of error than ranks assigned a "?" qualifier. Ratings that are not of concern (4-5) are not included.

S1 = Critically Imperilled: because of extreme rarity or because of some factor(s) making it especially vulnerable to extirpation. Typically five or fewer occurrences or very few remaining individuals (< 1,000).

S2 = Imperilled: because of rarity or because of some factor(s) making it very vulnerable to extirpation. Typically 6-20 occurrences or few remaining individuals (1,000-3,000).

S3 = Vulnerable: because rare and uncommon, or found in a restricted range (even if abundant at some locations), or because of other factors making it vulnerable to extirpation. Typically 21-100 occurrences or between 3,000 and 10,000 individuals.

SNR = Species not ranked.

S#? = Inexact numeric rank: denotes inexact numeric rank.

? = Element is not yet ranked (*i.e.*, S?), or has an inexact numerical rank (*e.g.*, S3?).

2 Potentially observed species. This species requires confirmation.

5.9.3.2 Hargreaves to Darfield Segment

Vegetation surveys were conducted along those locations of the Hargreaves to Darfield Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support rare plants and lichens. The survey methodology used and the complete results of the summer 2013 vegetation surveys are provided in the Vegetation Technical Report of Volume 5C. A list of rare plants that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

A search of the BC CDC identified seven occurrences of rare plant and lichen species within the Vegetation RSA in this segment (BC CDC 2013b). Of these previously observed species, five are vascular plant species which include bald sedge (ranked S2S3, Blue), bearded sedge (ranked S2, Blue), Hall's willowherb (ranked S2S3, Blue), meadow willow (ranked S2S3, Blue) and mountain moonwort (ranked S1, Red). Two of the previously observed species, Mexican mosquito fern and Haller's apple moss (near RK 490), are listed as Threatened under COSEWIC and *SARA* (COSEWIC 2013a, Environment Canada 2013o). There were no species designated under the BC IWMS previously observed along this segment. See the Vegetation Technical Report of Volume 5C for more detail.

Candidate critical habitat for whitebark pine, listed as Endangered under COSEWIC and *SARA*, occurs within 1 km of the proposed pipeline corridor along the Hargreaves to Darfield Segment (Environment Canada 2013p). Mapping of draft proposed critical habitat for whitebark pine was provided by Environment Canada (Environment Canada 2013p). Environment Canada provided Project-specific hard-copy maps of critical habitat for species at risk in BC (Environment Canada 2013p). The information on critical habitat is provided in this report with permission from Environment Canada and this information is subject to change since critical habitat mapping is not final until posted in a final recovery strategy on the Species at Risk Public Registry. Environment Canada makes no representation and gives no warranty of any kind with respect to the accuracy, usefulness, novelty, validity, scope, completeness or currency of the Canada Digital Data and expressly disclaims any implied warranty of merchantability or fitness for a particular purpose of the Canada Digital Data.

Candidate Critical Habitat for Species at Risk have been developed by Environment Canada, though a recovery strategy for whitebark pine is not final (Environment Canada 2013o). The critical habitat for whitebark pine is in the "early candidate (pre-review)" stage, meaning that the Recovery Strategy has not yet completed an internal review.

One potential COSEWIC and *SARA*-listed species was observed during the 2013 vegetation survey. Mexican mosquito fern (S2, Red-listed), which is listed as Threatened by COSEWIC and *SARA* (COSEWIC 2013a, Environment Canada 2013o), was observed in a pond approximately 43 m east of the centre of the proposed corridor near RK 749.9. At this location, there were thousands of individual plants along the edges of the pond. This species needs further confirmation. See Section 9.0 for details regarding supplemental studies. No species designated under the BC IWMS were observed. A total of 107 species listed by the BC CDC were observed during the 2013 vegetation survey (see Table 5.9-6).

TABLE 5.9-6

PLANT AND LICHEN SPECIES OF CONCERN IN THE HARGREAVES TO DARFIELD SEGMENT

Common Name	Scientific Name	Type	Provincial Rank[1] (Federal Rank)[2]	Provincial Listing[3]	Observed Number of Occurrences
Alaska moonwort	*Botrychium alaskense*	vascular plant	Not listed Ranked S1S3 by NatureServe	Not listed	1
bald sedge	*Carex tonsa*	vascular plant	S2S3	Blue	27
Canada anemone	*Anemone canadensis*	vascular plant	S2S3	Blue	1
crested wood fern	*Dryopteris cristata*	vascular plant	S2S3	Blue	2
cut notchwort	*Tritomaria exsecta*	liverwort	SNR Ranked S1 by NatureServe	Not listed	1
dainty moonwort	*Botrychium crenulatum*	vascular plant	S2S3	Blue	8
echo moonwort	*Botrychium echo*	vascular plant	S1S2	Red	1
finger ring	*Arctoparmelia incurve*	lichen	S2S3	Blue	1
fox sedge	*Carex vulpinoidea*	vascular plant	S2S3	Blue	1
golden saxifrage species[4]	*Chrysosplenium* sp.	vascular plant	Unknown	Unknown	1
least moonwort	*Botrychium simplex*	vascular plant	S2S3	Blue	1
Mexican mosquito fern[4]	*Azolla mexicana*	vascular plant	S2 (Threatened)	Red	1
Michigan moonwort	*Botrychium michiganense*	vascular plant	S1S3	Red	5
montane Dicranum moss	*Dicranum montanum*	moss	S3	Blue	4
moose moonwort	*Botrychium tunux*	vascular plant	S1S3	Red	1
mountain moonwort	*Botrychium montanum*	vascular plant	S1S2	Red	1
Peltigera lichen	*Peltigera conspersa*	lichen	Not listed	Not listed	3

TABLE 5.9-6 Cont'd

Common Name	Scientific Name	Type	Provincial Rank[1] (Federal Rank)[2]	Provincial Listing[3]	Observed Number of Occurrences
riverbank anemone	*Anemone virginiana* var *cylindroidea*	vascular plant	S3	Blue	1
silvery sedge	*Carex canescens* ssp. *disjuncta*	vascular plant	SU	Not listed	2
spoon-shaped moonwort	*Botrychium spathulatum*	vascular plant	S1	Red	1
stalked moonwort	*Botrychium pedunculosum*	vascular plant	S2	Red	16
tender sedge	*Carex tenera*	vascular plant	S2S3	Blue	3
upswept moonwort	*Botrychium ascendens*	vascular plant	S2	Red	2
western moonwort	*Botrychium hesperium*	vascular plant	S2S3	Blue	19
whip fork moss	*Dicranum flagellare*	moss	S3	Blue	2
white wintergreen	*Pyrola elliptica*	vascular plant	S2S3	Blue	1

Notes:

1 Provincial (S) ratings range from S1 (five or fewer occurrences or very few remaining hectares) to S5 (demonstrably secure, though it may be quite rare in parts of its range, especially at the periphery). Ranks may be combined (*e.g.*, S1S2). This indicates a larger margin of error than ranks assigned a "?" qualifier. Ratings that are not of concern (4-5) are not included.

S1 = Critically Imperilled: because of extreme rarity or because of some factor(s) making it especially vulnerable to extirpation. Typically five or fewer occurrences or very few remaining individuals (< 1,000).

S2 = Imperilled: because of rarity or because of some factor(s) making it very vulnerable to extirpation. Typically 6-20 occurrences or few remaining individuals (1,000-3,000).

S3 = Vulnerable: because rare and uncommon, or found in a restricted range (even if abundant at some locations), or because of other factors making it vulnerable to extirpation. Typically 21-100 occurrences or between 3,000 and 10,000 individuals.

S#S# = Range Rank: a numeric range rank (*e.g.*, S2S3) is used to indicate the range of uncertainty about the exact status of the element.

S#? = Inexact numeric rank: denotes inexact numeric rank.

? = Element is not yet ranked (*i.e.*, S?) or has an inexact numerical rank (*e.g.*, S3?).

SU = Unrankable: currently unrankable due to lack of information or due to substantially conflicting information about status or trends.

SNR = Species not ranked

2 Federal ratings include species listed by COSEWIC (2013b) and listed on Schedule 1 of *SARA* (Environment Canada 2013o). Species listed as “Extirpated”, “Not at Risk” or “Data Deficient” were not included in the table. Federal ratings are current to November 2013.

Threatened = A species likely to become endangered if limiting factors are not reversed.

3 Red-listed refers to a species that is Extirpated, Endangered, or Threatened while Blue-listed refers to a species of Special Concern under the BC *Wildlife Act*.

4 Potentially observed species. This species requires confirmation. See Section 9.0 for details regarding supplemental surveys.

5.9.3.3 Black Pines to Hope Segment

Vegetation surveys were conducted along those locations of the Black Pines to Hope Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support rare plants and lichens. The survey methodology used and the complete results of the 2013 vegetation surveys are provided in the Vegetation Technical Report of Volume 5C. A list of rare plants that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in the Vegetation Technical Report of Volume 5C.

A search of the BC CDC database identified eight occurrences of rare plant and lichen species within the Vegetation RSA along this segment (BC CDC 2013b). Of these previously observed species, seven are vascular plant species which include bearded sedge (ranked S2, Red-listed), blue grama (ranked S2, Red-listed), Hall’s willowherb (ranked S2S3, Blue-listed), ovalpurse (ranked S3, Blue-listed), Suksdorf’s lupine (ranked S2, Red-listed), toothcup meadow-foam (ranked S1, Red-listed) and wedgescale orache (ranked S3, Blue-listed). There was one previously observed non-vascular species, which is alkaline wing-nerved moss (ranked S2, Red-listed). One of the previously observed species, toothcup meadow-foam, is listed as Endangered under COSEWIC and *SARA* (COSEWIC 2013a, Environment Canada 2013o). There were no species designated under the BC IWMS previously observed along this segment. See the Vegetation Technical Report of Volume 5C for more detail.

Candidate critical habitat for whitebark pine occurs within 1 km of the proposed pipeline corridor along the Black Pines to Hope Segment (Environment Canada 2013p). There is proposed critical habitat for toothcup meadow-foam overlapping the proposed pipeline corridor in the Black Pines to Hope Segment (Environment Canada 2013p). Candidate Critical Habitat for Species at Risk have been developed by Environment Canada, though recovery strategies for toothcup meadow-foam and whitebark pine are not final (Environment Canada 2013o). The critical habitat for whitebark pine is in the "early candidate (pre-review)" stage, meaning that the Recovery Strategy has not yet completed an internal review. The toothcup meadow-foam critical habitat is in the "candidate (jurisdictional review)" stage, meaning that the Recovery Strategy has completed an internal review and has been partially vetted by the Government of BC and (if relevant) other *Species at Risk Act* participating agencies (*e.g.*, DFO or Parks Canada).

No COSEWIC or *SARA*-listed species were observed during the 2013 vegetation survey of this proposed pipeline segment. In addition, no species designated under the BC IWMS were observed. There were 13 BC CDC-listed plant species observed during the 2013 vegetation surveys (see Table 5.9-7).

TABLE 5.9-7

PLANT AND LICHEN SPECIES OF CONCERN IN THE BLACK PINES TO HOPE SEGMENT

Common Name	Scientific Name	Type	Provincial Rank[1]	Provincial Listing[2]	Observed Number of Occurrences
Alaska moonwort	*Botrychium alaskense*	vascular plant	Not listed Ranked S1S3 by NatureServe	Not listed	1
birdnest vinyl	*Leptogium tenuissimum*	lichen	S2?	Red	1
brown-eyed wolf	*Letharia columbiana*	lichen	S3?	Blue	1
campion species	*Silene* sp.	vascular plant	Unknown	Unknown	1
many-headed sedge	*Carex sychnocephala*	vascular plant	S3	Blue	1
mountain candlewax	*Ahtiana sphaerosporella*	lichen	S2S3	Blue	1
Peltigera lichen	*Peltigera* sp. nov *blue*	lichen	Not listed	Not listed	1
Peltigera lichen	*Peltigera conspersa*	lichen	Not listed	Not listed	1
Racomitrium moss	*Racomitrium affine*	moss	S2S3	Blue	1
slender spike-rush	*Eleocharis nitida*	vascular plant	S1	Red	1
spotted beard	*Usnea glabrescens*	lichen	S3	Blue	1
Syntrichia moss	*Syntrichia caninervis*	moss	S3?	Blue	1
Usnea lichen	*Usnea quasirigida*	lichen	Not listed	Not listed	1

Notes: 1 Provincial (S) ratings range from S1 (five or fewer occurrences or very few remaining hectares) to S5 (demonstrably secure, though it may be quite rare in parts of its range, especially at the periphery). Ranks may be combined (*e.g.*, S1S2). This indicates a larger margin of error than ranks assigned a "?" qualifier. Ratings that are not of concern (4-5) are not included.

S1 = Critically Imperilled: because of extreme rarity or because of some factor(s) making it especially vulnerable to extirpation. Typically five or fewer occurrences or very few remaining individuals (< 1,000).

S3 = Vulnerable: because rare and uncommon, or found in a restricted range (even if abundant at some locations), or because of other factors making it vulnerable to extirpation. Typically 21-100 occurrences or between 3,000 and 10,000 individuals.

2 Under the BC *Wildlife Act*, Red-listed refers to a species that is Extirpated, Endangered, or Threatened in BC. Blue-listed refers to a species of Special Concern in BC.

5.9.3.4 Hope to Burnaby Segment

Vegetation surveys were conducted along those locations of the Hope to Burnaby Segment that were representative of the different vegetation types in the area, as well as those with a high potential to support rare plants and lichens. The survey methodology used and the complete results of the 2013 vegetation surveys are provided in the Vegetation Technical Report of Volume 5C. A list of rare plants that have the potential to occur within the Vegetation RSA of this proposed pipeline segment is included in the Vegetation Technical Report of Volume 5C.

A search of the BC CDC identified 16 occurrences of rare plant and lichen species within the Vegetation RSA in this segment (BC CDC 2013b). One of the previously observed vascular plant species, tall bugbane (S1, Red) is listed as Endangered under COSEWIC, *SARA* and is listed under the BC IWMS (COSEWIC 2013a, Environment Canada 2013o). Another vascular plant species, Vancouver Island beggarticks (S3, Blue), is listed as Special Concern under COSEWIC and *SARA* (COSEWIC 2013a, Environment Canada 2013o). One previously observed lichen species, peacock vinyl lichen (S1S2, Red), is listed as Special Concern under COSEWIC (COSEWIC 2013a). Candidate critical habitat does not yet exist for Vancouver Island beggarticks, Haller's apple moss, tall bugbane, Mexican mosquito fern or peacock vinyl lichen (Government of Canada 2013). See the Vegetation Technical Report of Volume 5C for more detail.

No COSEWIC or *SARA*-listed species were observed during the 2013 vegetation survey of this proposed pipeline segment. In addition, no species designated under the BC IWMS were observed. One BC CDC-listed plant species was observed during the 2013 vegetation surveys: three occurrences of pacific waterleaf (*Hydrophyllum tenuipes*), ranked S2, Red-listed, were observed along this segment.

5.9.3.5 Burnaby to Westridge Segment

A list of rare plants and lichens that have the potential to occur within the Vegetation RSA of the Burnaby to Westridge Segment is included in Appendix B of the Vegetation Technical Report of Volume 5C.

A search of the BC CDC identified no previously observed rare plant or lichen species within the Vegetation RSA in this segment (BC CDC 2013b).

Due to lack of land access in 2013, vegetation surveys were not conducted on the Burnaby to Westridge Segment. Vegetation surveys on this segment are planned in 2014.

5.9.4 Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern

According to the Alberta *Weed Control Act,* Prohibited Noxious weeds must be destroyed and Noxious weeds must be controlled by the owner or occupant of those lands on which the weeds are present. In BC, Provincial Noxious weeds are those that must be controlled in all regions and Regional Noxious weeds are those that must be controlled in the region(s) for which they are listed. There are many additional, non-listed species that are introduced to Alberta and BC (*i.e.*, non-native), including some agronomic and horticultural species, that can be invasive in certain land uses. Additional invasive non-native species of concern are identified through consultation. This indicator will inform efforts to address the NEB *Filing Manual* requirements to consider weed control measures and seed mixes.

Forest health and forest pests are discussed under the human occupancy and resource use element in Section 5.0 of Volume 5B and in the Managed Forest Areas and Forest Health Technical Report of Volume 5D.

5.9.4.1 Edmonton to Hinton Segment

Stakeholders, including attendees of the Hinton Community Workshop, Edmonton West Community Workshop and Edson Community Workshop as well as representatives of Strathcona County, the City of Edmonton, the City of Spruce Grove, the Town of Stony Plain, the Village of Wabamun, Parkland County and Yellowhead County, were contacted regarding weeds of concern and their associated websites were consulted. Stakeholders expressed concern regarding all species regulated in the Alberta *Weed Control Act* as well as those listed and non-listed species identified in the Vegetation Technical Report of Volume 5C (Anderson, Laubham, Leskiw, Pichette, Zacharias pers. comm., City of Edmonton 2013, Parkland County 2013b, Strathcona County 2013). Listed and non-listed, non-native species that were observed during 2013 vegetation surveys along the Edmonton to Hinton Segment of the Project are also included in the Vegetation Technical Report of Volume 5C. Table 5.9-8 lists the Prohibited Noxious and Noxious species described by stakeholders as being of concern during consultation and indicates which of these were observed during the 2013 vegetation surveys along this segment.

TABLE 5.9-8

PROHIBITED NOXIOUS AND NOXIOUS WEED SPECIES IDENTIFIED DURING STAKEHOLDER CONSULTATION AND VEGETATION SURVEYS FOR THE EDMONTON TO HINTON SEGMENT

Common Name[1]	Scientific Name[1]	Provincial Status	Observed During 2013 Vegetation Surveys
bighead knapweed	*Centaurea macrocephala*	Prohibited Noxious	--
garlic mustard	*Alliaria petiolata*	Prohibited Noxious	--
giant hogweed	*Heracleum mantegazzianum*	Prohibited Noxious	--
himalayan balsam	*Impatiens glandulifera*	Prohibited Noxious	--
meadow hawkweed	*Hieracium caespitosum*	Prohibited Noxious	Yes
orange hawkweed	*Hieracium aurantiacum*	Prohibited Noxious	Yes
purple loosestrife	*Lythrum salicaria*	Prohibited Noxious	--
rough-fruited cinquefoil	*Potentilla recta*	Prohibited Noxious	Yes
Canada thistle (creeping thistle)	*Cirsium arvense*	Noxious	Yes
common burdock	*Arctium minus*	Noxious	--
common mullein	*Verbascum thapsus*	Noxious	--
common tansy	*Tanacetum vulgare*	Noxious	Yes
creeping bellflower	*Campanula rapunculoides*	Noxious	--
dame's rocket	*Hesperis matronalis*	Noxious	--
field scabious	*Knautia arvensis*	Noxious	--
leafy spurge	*Euphorbia esula*	Noxious	Yes
ox-eye daisy	*Chrysanthemum leucanthemum*	Noxious	Yes
perennial sow thistle	*Sonchus arvensis*	Noxious	Yes
scentless chamomile	*Matricaria perforata*	Noxious	Yes
tall buttercup	*Ranunculus acris*	Noxious	Yes
white cockle (bladder campion)	*Silene pratensis*	Noxious	Yes
yellow toadflax (common toadflax)	*Linaria vulgaris*	Noxious	Yes

Note: 1 Species nomenclature is determined according to the list of all elements in Alberta (ACIMS 2013), with more current taxonomic information drawn from NatureServe (2012), when necessary. Where the Alberta *Weed Control Act* nomenclature differs from these sources, the *Weed Control Act* name for the species has been provided in brackets following the ACIMS name.

5.9.4.2 Hargreaves to Darfield Segment

Stakeholders, including attendees of the Clearwater Community Workshop as well as representatives of the Regional District of Fraser-Fort George (RDFFG) Regional District, the TNRD, the Northwest Invasive Plant Council (NWIPC) and the Southern Interior Weed Management Committee (SIWMC) were contacted regarding weeds of concern and their associated websites were consulted. These stakeholders expressed concerns regarding a number of non-native and invasive species. Stakeholders' concerns are discussed in the Vegetation Technical Report of Volume 5C (Fox pers. comm., NWIPC 2013, SIWMC 2013, TNRD 2010). The Provincial Noxious weeds of concern identified by stakeholders during consultation are listed in Table 5.9-9. Table 5.9-9 also indicates which of these Provincial Noxious weeds were observed during the 2013 vegetation surveys within this segment. Non-native and invasive species that were observed during 2013 vegetation surveys along the Hargreaves to Darfield Segment are included in the Vegetation Technical Report of Volume 5C.

TABLE 5.9-9

PROVINCIAL NOXIOUS WEED SPECIES IDENTIFIED DURING STAKEHOLDER CONSULTATION AND VEGETATION SURVEYS FOR THE HARGREAVES TO DARFIELD SEGMENT

Common Name[1]	Scientific Name[1]	Provincial Status	Observed During 2013 Vegetation Surveys
Canada thistle	*Cirsium arvense*	Provincial Noxious	Yes
common hound's-tongue	*Cynoglossum officinale*	Provincial Noxious	Yes
Dalmatian toadflax	*Linaria genistifolia* ssp. *Dalmatica* (*Linaria dalmatica*)	Provincial Noxious	Yes
diffuse knapweed	*Centaurea diffusa*	Provincial Noxious	Yes

TABLE 5.9-9 Cont'd

Common Name[1]	Scientific Name[1]	Provincial Status	Observed During 2013 Vegetation Surveys
scentless mayweed (scentless chamomile)	*Tripleurospermum inodorum* (*Matricaria maritima*)	Provincial Noxious	Yes
spotted knapweed	*Centaurea stoebe* ssp. *micranthos* (*Centaurea maculosa*)	Provincial Noxious	Yes

Note: 1 Species nomenclature and the status of species as native or not is determined according to the BC Species and Ecosystem Explorer (BC MOE 2013f), with more current taxonomic information drawn from NatureServe (2012), when necessary. Where the BC *Weed Control Act* nomenclature differs from these sources, the *Weed Control Act* name for the species has been provided in brackets following the ACIMS or BC CDC name. Where no species nomenclature is available from the BC Species and Ecosystem Explorer (BC MOE 2013f), only the BC *Weed Control Act* name is provided.

5.9.4.3 Black Pines to Hope Segment

Stakeholders, including attendees of the Kamloops ESA Workshop, Kamloops Community Workshop, Merritt Community Workshop and Hope Community Workshop as well as representatives of the TNRD, the FVRD, the SIWMC and the Fraser Valley Invasive Plant Council, were contacted regarding weeds of concern and their associated websites were consulted. These stakeholders expressed concerns regarding a number of native and non-native species. Stakeholders' concerns are discussed in the Vegetation Technical Report of Volume 5C (Fox pers. comm., Fraser Valley Invasive Plants Council 2012, FVRD 2008a, SIWMC 2013, TNRD 2010). The Provincial Noxious weeds of concern identified by stakeholders during consultation are listed in Table 5.9-10. Table 5.9-10 also indicates which of these Provincial Noxious weeds were observed during the 2013 vegetation surveys within this segment. Non-native and invasive species that were observed during 2013 vegetation surveys along the Black Pines to Hope Segment are included in the Vegetation Technical Report of Volume 5C.

TABLE 5.9-10

PROVINCIAL NOXIOUS WEED SPECIES IDENTIFIED DURING STAKEHOLDER CONSULTATION AND VEGETATION SURVEYS FOR THE BLACK PINES TO HOPE SEGMENT

Common Name[1]	Scientific Name[1]	Provincial Status	Observed During 2013 Vegetation Surveys
Canada thistle	*Cirsium arvense*	Provincial Noxious	Yes
common hound's-tongue	*Cynoglossum officinale*	Provincial Noxious	Yes
Dalmatian toadflax	*Linaria genistifolia* ssp. *Dalmatica* (*Linaria dalmatica*)	Provincial Noxious	Yes
diffuse knapweed	*Centaurea diffusa*	Provincial Noxious	Yes
scentless mayweed (scentless chamomile)	*Tripleurospermum inodorum* (*Matricaria maritima*)	Provincial Noxious	Yes
spotted knapweed	*Centaurea stoebe* ssp. *micranthos* (*Centaurea maculosa*)	Provincial Noxious	Yes

Note: 1 Species nomenclature and the status of species as native or not is determined according to the BC Species and Ecosystem Explorer (BC MOE 2013f), with more current taxonomic information drawn from NatureServe (2012), when necessary. Where the BC *Weed Control Act* nomenclature differs from these sources, the *Weed Control Act* name for the species has been provided in brackets following the ACIMS or BC CDC name. Where no species nomenclature is available from the BC Species and Ecosystem Explorer (BC MOE 2013f), only the BC *Weed Control Act* name is provided.

5.9.4.4 Hope to Burnaby Segment

Stakeholders, including attendees of the Hope Community Workshop, Abbotsford Community Workshop, Coquitlam Community Workshop and Langley Community Workshop as well as representatives of the FVRD, the GVRD, the Fraser Valley Invasive Plant Council and the Invasive Species Council of Metro Vancouver, were contacted regarding weeds of concern and their associated websites were consulted. These stakeholders expressed concerns regarding a number of native and non-native species. Stakeholders' concerns are discussed in the Vegetation Technical Report of Volume 5C (Fraser Valley Invasive Plants Council 2012, FVRD 2008a, Metro Vancouver 2011b). The Provincial Noxious weeds of concern identified by stakeholders during consultation are listed in Table 5.9-11. Table 5.9-11 also indicates which of these Provincial Noxious weeds were observed during the 2013 vegetation surveys within this segment. Non-native and invasive species that were observed during 2013 vegetation surveys along the Hope to Burnaby Segment of the Project are also included in the Vegetation Technical Report of Volume 5C.

TABLE 5.9-11

PROVINCIAL NOXIOUS WEED SPECIES IDENTIFIED DURING STAKEHOLDER CONSULTATION AND VEGETATION SURVEYS FOR THE HOPE TO BURNABY SEGMENT

Common Name[1]	Scientific Name[1]	Provincial Status	Observed During 2013 Vegetation Surveys
Canada thistle	*Cirsium arvense*	Provincial Noxious	Yes
Japanese knotweed	*Fallopia japonica*	Provincial Noxious	Yes
spotted knapweed	*Centaurea stoebe ssp. micranthos* (*Centaurea maculosa*)	Provincial Noxious	Yes
tansy ragwort	*Senecio jacobaea*	Provincial Noxious	Yes

Note: 1 Species nomenclature and the status of species as native or not is determined according to the BC Species and Ecosystem Explorer (BC MOE 2013f), with more current taxonomic information drawn from NatureServe (2012), when necessary. Where the BC *Weed Control Act* nomenclature differs from these sources, the *Weed Control Act* name for the species has been provided in brackets following the ACIMS or BC CDC name. Where no species nomenclature is available from the BC Species and Ecosystem Explorer (BC MOE 2013f), only the BC *Weed Control Act* name is provided.

5.9.4.5 Burnaby to Westridge Segment

Stakeholders, including attendees of the Burnaby Community Workshop as well as the GVRD, represented by the Invasive Species Council of Metro Vancouver, were contacted regarding weeds of concern and the associated websites were consulted. These stakeholders expressed concerns regarding a number of native and non-native species. Stakeholders' concerns are discussed in the Vegetation Technical Report of Volume 5C (Invasive Species Council of Metro Vancouver 2013, Metro Vancouver 2011b). The Provincial Noxious weeds of concern identified by stakeholders during consultation are listed in Table 5.9-12.

No vegetation surveys were conducted within the Burnaby to Westridge Segment in 2013. Surveys are expected for this segment in 2014.

TABLE 5.9-12

PROVINCIAL NOXIOUS WEED SPECIES IDENTIFIED DURING STAKEHOLDER CONSULTATION FOR THE BURNABY TO WESTRIDGE SEGMENT

Common Name[1]	Scientific Name[1]	Provincial Status	Observed During 2013 Vegetation Surveys
Bohemian knotweed	*Fallopia x bohemica*	Provincial Noxious	N/A
bur chervil	*Anthriscus caucalis*	Provincial Noxious	N/A
Canada thistle	*Cirsium arvense*	Provincial Noxious	N/A
common reed	*Phragmites australis ssp. australis*	Provincial Noxious	N/A
Crupina	*Crupina vulgaris*	Provincial Noxious	N/A
Dalmatian toadflax	*Linaria genistifolia ssp. dalmatica* (*Linaria dalmatica*)	Provincial Noxious	N/A
diffuse knapweed	*Centaurea diffusa*	Provincial Noxious	N/A
English cordgrass	*Spartina anglica*	Provincial Noxious	N/A
flowering-rush	*Butomus umbellatus*	Provincial Noxious	N/A
garlic mustard	*Alliaria petiolata*	Provincial Noxious	N/A
giant hogweed	*Heracleum mantegazzianum*	Provincial Noxious	N/A
giant knotweed	*Fallopia sachalinensis*	Provincial Noxious	N/A
Gorse	*Ulex europaeus*	Provincial Noxious	N/A
Himalayan knotweed	*Persicaria wallichii* (*Polygonum polystachyum*)	Provincial Noxious	N/A
Japanese knotweed	*Fallopia japonica*	Provincial Noxious	N/A

TABLE 5.9-12 Cont'd

Common Name[1]	Scientific Name[1]	Provincial Status	Observed During 2013 Vegetation Surveys
leafy spurge	*Euphorbia esula*	Provincial Noxious	N/A
milk thistle	*Silybum marianum*	Provincial Noxious	N/A
scentless mayweed (scentless chamomile)	*Tripleurospermum inodorum* (*Matricaria maritima*)	Provincial Noxious	N/A
spotted knapweed	*Centaurea stoebe ssp. micranthos* (*Centaurea maculosa*)	Provincial Noxious	N/A
tansy ragwort	*Senecio jacobaea*	Provincial Noxious	N/A
yellow iris (yellow flag iris)	*Iris pseudacorus*	Provincial Noxious	N/A
yellow starthistle	*Centaurea solstitialis*	Provincial Noxious	N/A

Note: 1 Species nomenclature and the status of species as native or not is determined according to the BC Species and Ecosystem Explorer (BC MOE 2013f), with more current taxonomic information drawn from NatureServe (2012), when necessary. Where the BC *Weed Control Act* nomenclature differs from these sources, the *Weed Control Act* name for the species has been provided in brackets following the ACIMS or BC CDC name. Where no species nomenclature is available from the BC Species and Ecosystem Explorer (BC MOE 2013f), only the BC *Weed Control Act* name is provided.

5.9.5 Traditional Ecological Knowledge

TEK was collected in partnership between TERA and members of potentially affected Aboriginal communities to discuss the role of the local plants for local peoples and cultures, and to document traditional values and observations regarding vegetation aspects of the local and regional landscape. The collection of TEK, which focused on Aboriginal experiential knowledge of the land and field reconnaissance, was conducted along Crown lands as well as some private lands potentially disturbed by Project construction, including associated physical works and activities.

During the field surveys, traditional methods of resource procurement were discussed, as well as modern methods currently employed. Seasonality of resource harvesting, species of traditional importance, identification of traditionally harvested plants, description of uses and preparation techniques, as well as plant rarity and abundance was also important information shared by the Aboriginal participants. Geographical locations were identified, as were areas that are not used and the reasons why. Potential mitigation measures to reduce any Project-related effects on a resource were also discussed during the vegetation field surveys.

Concerns identified during engagement include clearing of vegetation, contamination of plants through use of herbicides and pesticides and loss or alteration of traditional use sites for plant gathering. The locations and uses of the medicinal plants and the locations of important harvesting areas is knowledge held by the TEK participants and proprietary to the community. Detailed TEK results and methodologies can be found within the Vegetation Technical Report of Volume 5C.

5.10 Wildlife and Wildlife Habitat

This subsection discusses the existing conditions for wildlife and wildlife habitat within the Wildlife RSA (Figures 5.10-1 to 5.10-4). The Wildlife RSA encompasses the Project Footprint, the LSA and the broader surrounding area where there is potential for cumulative and/or wider-spread Project effects. The RSA is a 30 km band generally centred on the proposed pipeline corridor (*i.e.*, extending 15 km on both sides from the centre of the pipeline corridor). The existing conditions, including shared ATK and TEK, are characterized for each of the five proposed pipeline segments based on the literature and desktop review in Sections 5.10.1 to 5.10.5.

TEK was collected in partnership between TERA and members of participating Aboriginal communities. During the wildlife field surveys, traditional methods of resource procurement were discussed, as well as modern methods currently employed. Seasonality of resource harvesting was also important information shared by the Aboriginal participants. Geographical locations were identified, as were areas that are not used and the reasons why. Potential mitigation measures to reduce any Project-related effects on a resource were also discussed during the biophysical field studies.

The indicators selected for this element are listed below:

- grizzly bear;
- moose;
- woodland caribou;
- forest furbearers;
- coastal riparian small mammals;
- bats;
- grassland/shrub steppe birds;
- mature/old forest birds;
- early seral forest birds;
- riparian and wetland birds;
- wood warblers;
- short-eared owl;
- rusty blackbird;
- flammulated owl;
- Lewis's woodpecker;
- Williamson's sapsucker;
- western screech owl;
- great blue heron;
- spotted owl;
- bald eagle;
- common nighthawk;
- northern goshawk;
- olive-sided flycatcher;
- pond-dwelling amphibians;
- stream-dwelling amphibians; and
- arid habitat snakes.

The rationale for the selection of indicators is provided in Section 7.2.10. The potential Project-related effects and mitigation pertaining to wildlife and wildlife habitat are discussed in Section 7.2.10. Refer to the Wildlife Technical Report of Volume 5C for additional details on existing conditions for wildlife and wildlife habitat.

Detailed species accounts were prepared and wildlife habitat models were completed to estimate wildlife habitat effectiveness within the Wildlife LSA. The full report can be found in the Wildlife Modelling and Species Accounts Technical Report (Volume 5C).

5.10.1 Edmonton to Hinton Segment

The Edmonton to Hinton Segment crosses a mosaic of land uses and habitat types, including suburban areas associated with cities and towns, agricultural fields (*i.e.*, cultivation and hay fields), pasture and forested areas. Suburban and agricultural areas are predominant along the east end of this segment, whereas forested areas are predominant along the west end. These areas include sections of deciduous, coniferous and mixedwood forest consisting of trembling aspen, white spruce, black spruce, jack pine, balsam fir and less commonly balsam poplar and paper birch. Forest harvesting activities have occurred in upland mixedwood forests and these areas are at various stages of regeneration. The Edmonton to Hinton Segment crosses two wildfire burns that occurred within the last 40 years: 2009 (RK 188.7 to RK 189.4); and 2010 (RK 135.9 to 136.3) (AESRD 2013f). Most of the wetlands crossed or located in the vicinity of the proposed pipeline segment are surrounded by cultivation or tame pasture with larger expanses of treed bogs and fens encountered towards the western half of the proposed pipeline segment. Terrain is generally level to gently undulating along the Edmonton to Hinton Segment with moderate to steep slopes encountered at watercourse crossings (*i.e.*, the North Saskatchewan, Pembina and McLeod rivers) and gently to moderately undulating terrain within the Lower Foothills and Montane natural subregions.

The following subsections describe the provincially identified wildlife areas, Environmentally Significant Areas, parks and protected areas, PNTs, species with special conservation status and ATK and TEK along the Edmonton to Hinton Segment.

5.10.1.1 Provincially Identified Wildlife Areas

A summary of provincially identified wildlife areas in relation to the Edmonton to Hinton Segment is provided in Table 5.10-1.

TABLE 5.10-1

PROVINCIALLY IDENTIFIED WILDLIFE AREAS – EDMONTON TO HINTON SEGMENT

Wildlife Area	Detail	Legal Location	RK Range	Approximate Length (km)
Key Wildlife and Biodiversity Zone	North Saskatchewan River	3 and 4-52-25 W4M	32.8 to 34.1	1.3
	North Saskatchewan River	NW 8-52-25 W4M	36.6 to 37.1	0.5
	Athabasca River	1-10-52-24 W5M to 16-32-51-24 W5M	307.5 to 311.5	3.7
Special Access Area	--	7-4-53-22 W5M to 12-36-52-23 W5M	286.8 to 292.5	5.9
		16-25-50-26 W5M to 11-33-49-26 W5M	329.0 to 339.6	10.6
Grizzly Bear Secondary Area	Grande Cache Population Unit	4-27-52-23 W5M to 11-33-49-26 W5M	297.2 to 339.6	40.4
Sensitive Raptor Range	Bald Eagle	4-5-53-23 W4M to 11-2-53-1 W5M	0.0 to 68.8	68.8
Sharp-Tailed Grouse Range	--	4-5-53-23 W4M to 14-2-53-1 W5M	0.0 to 68.8	68.8
Trumpeter Swan Waterbody	Unnamed Lake (400 m from pipeline corridor)	SW 22-53-18 W5M	241.4 to 243.1	1.7
	Annabel Lake (700 m from pipeline corridor)	34-52-19 W5M	253.9 to 254.6	0.7
	Unnamed Lake (200 m from pipeline corridor)	W 5-53-19 W5M	256.8 to 258.6	1.8

Source: AESRD 2013g

5.10.1.2 Environmentally Significant Areas

The proposed Edmonton to Hinton Segment is located within five provincial Environmentally Significant Areas (70, 99, 441, 442, 690) (Fiera Biological Consulting 2009). The details are provided in the Wildlife Technical Report of Volume 5C. Environmentally Significant Areas do not have regulatory guidelines or development restrictions.

5.10.1.3 Parks and Protected Areas

The proposed pipeline corridor is not located within a provincial park in this segment but is located near to Wabamun Lake and Obed Lake provincial parks and the Yates Natural Area. It is also located within the DUC Level 1 Priority Landscapes, Prairie Pothole Region and Western Boreal Forest. The Prairie Pothole Region is a primary breeding area for waterfowl and the Western Boreal Forest provides breeding, migration, moulting and staging habitat for waterfowl (DUC 2013). The proposed pipeline corridor is not located within or adjacent to an IBA, Migratory Bird Sanctuary, National Wildlife Area, Western Hemisphere Shorebird Reserve, Ramsar wetland or Biosphere Reserve (AltaLIS 2008, Bird Studies Canada and Nature Canada 2012, Bureau of the Convention on Wetlands 2013, Environment Canada 2012n, United Nations Educational, Scientific and Cultural Organization [UNESCO] 2012, WHSRN 2013).

5.10.1.4 Protective Notation

A search of the GLIMPS for wildlife-related Crown dispositions identified 10 PNTs that are crossed by the Edmonton to Hinton Segment (Alberta Energy 2013). Table 5.10-2 describes the PNTs that are held by the AESRD Fish and Wildlife Division pertaining to habitat conservation.

TABLE 5.10-2

PNTS FOR WILDLIFE HABITAT – EDMONTON TO HINTON SEGMENT

Code	Type	Legal Location	RK Range	Activity Detail Information and Relevance to the Project[1]
PNT 980061	PNT (Fragmented Land Pattern)	NW 13-53-6 W5M	118.1 to 118.9	Activity Detail Information: N/A Relevance to Project: Forested. Railway runs southeast to northwest across quarter-section. Proposed corridor parallels the existing TMPL right-of-way.
PNT 870456	PNT (Ungulate Winter Range [UWR])	NW 22-53-10 W5M	161.0 to 161.8	Activity Detail Information: N/A Relevance to Project: Forested. Proposed corridor parallels the existing TMPL right-of-way.
PNT 780290	PNT (Fish and Wildlife Resource Management Area)	SW 35-53-13 W5M	189.1 to 189.9	Activity Detail Information: N/A Relevance to Project: Forested. Proposed corridor parallels the existing TMPL right-of-way.
PNT 980160	PNT (Research Site Structure)	NE 12-51-25 W5M	319.3 to 319.9	Activity Detail Information: Exclosure established to determine the effects of wildlife and horse grazing on tree regeneration and species composition in a regenerating black spruce-white spruce forest. Relevance to Project: Forested. New clearing required.
PNT 020232	PNT (Rare and Endangered Species Habitat Protection Area)	NW 3-50-26 W5M	336.9 to 337.8	Activity Detail Information: Fish and Wildlife Division recommends the following conditions be applied near long-toed salamander breeding ponds through the land use permit system: 1) April 1 to Sept 30 (breeding season), no activity within 100 m of the water's edge of identified ponds; 2) no roads, wells, or pipelines within 100 m of the water's edge of identified ponds; 3) seismic lines must be hand-cut within 100 m of the water's edge of identified ponds; 4) no timber harvesting within 100 m of the water's edge of identified ponds; and 5) no grazing or range improvements. Contact: Regional Endangered species specialist in Edson. Relevance to Project: Forested. Proposed corridor parallels the existing TMPL right-of-way.

5.10.1.5 Species with Special Conservation Status

A desktop review of the potential wildlife species of concern list found that species with special conservation status that are provincially-listed (AESRD 2012b) or federally-listed on Schedule 1 of *SARA* (Environment Canada 2013o) or by COSEWIC (2013a) that have potential to occur along the Edmonton to Hinton Segment are listed in Table 5.10-3. A search of the Fisheries and Wildlife Management Information System (FWMIS) records identified occurrences of provincially and federally-listed wildlife species of concern (AESRD 2012c) (Table 5.10-3).

TABLE 5.10-3

SPECIES WITH SPECIAL CONSERVATION STATUS – EDMONTON TO HINTON SEGMENT

Common Name	Provincial Designations	Federal Designations
BIRDS		
Bank swallow	S5[1] Secure[3]	Threatened[5]
Barn swallow	S4 (W)[1] Sensitive[3]	Threatened[5]
Barred owl	S3S4 (W)[1] Special Concern[2] Sensitive[3]	--
Bobolink	S2S3 (W)[1] Sensitive[3]	Threatened[5]
Canada warbler	S3S4 (T)[1] Sensitive[3]	Threatened[4,5]
Common nighthawk	S4 (T)[1] Sensitive[3]	Threatened[4,5]
Harlequin duck	S3 (T)[1] Special Concern[2] Sensitive[3]	--
Horned grebe	S3 (W)[1] Sensitive[3]	Special Concern[5]
Lewis's woodpecker	SU (W)[1] Sensitive[3]	Threatened[4,5]
Loggerhead shrike	S3 (T)[1] Special Concern[2] Sensitive[3]	Threatened[4,5]
Olive-sided flycatcher	S3 (T)[1] May Be at Risk[3]	Threatened[4,5]
Peregrine falcon, *anatum* ssp.	S2S3[1] Threatened[2] At Risk[3]	Special Concern[4,5]
Rusty blackbird	S4 (T)[1] Sensitive[3]	Special Concern[4,5]
Short-eared owl	S3 (T)[1] May Be at Risk[3]	Special Concern[4,5]
Sprague's pipit	S3S4 (T)[1] Special Concern[2] Sensitive[3]	Threatened[4,5]
Trumpeter swan	S2S3 (T)[1] Threatened[2] At Risk[3]	Not at Risk[5]
Western grebe	S3 (W)[1] Special Concern[2] Sensitive[3]	--
White-winged scoter	S3S4 (W)[1] Special Concern[2] Sensitive[3]	--
Yellow rail	SU (T)[1]	Special Concern[4,5]
MAMMALS		
American badger, *taxus* ssp.	S4[1] Sensitive[3]	Special Concern[5]
Grizzly bear, western population	S2 (T)[1] Threatened[2] At Risk[3]	Special Concern[5]
Little brown myotis	S5 (T.h)[1] Secure[3]	Endangered[5]
Northern myotis	S2S3 (T.h)[1] May Be at Risk[3]	Endangered[5]

TABLE 5.10-3 Cont'd

Common Name	Provincial Designations	Federal Designations
Vagrant shrew	S1 (T)[1] May Be at Risk[3]	--
Wolverine	S3 (T)[1] May Be at Risk[3]	Special Concern[5]
REPTILES AND AMPHIBIANS		
Canadian toad	S3 (T)[1] May Be at Risk[3]	Not at Risk[5]
Long-toed salamander	S3 (T)[1] Special Concern[2] Sensitive[3]	--
Tiger salamander	S4[1] Secure[3]	Special Concern[5]
Western toad	S3 (T)[1] Sensitive[3]	Special Concern[4,5]
INVERTEBRATES		
Monarch	S3[1] Sensitive[3]	Special Concern[4,5]

Notes: Definitions of Status Designations are provided in Appendix C of the Wildlife Technical report of Volume 5C. Federal ratings are current to November 2013.

1 Provincial (S) rank assigned by ACIMS (2013).

2 Species listed under the Alberta *Wildlife Act* and *Wildlife Regulation* (AESRD 2012d).

3 Status designation assigned in *The 2010 General Status of Alberta Wild Species* (ASRD 2011).

4 Species listed under Schedule 1 of *SARA* (Environment Canada 2013o).

5 Species listed under COSEWIC (2013a).

5.10.1.6 Traditional Ecological Knowledge

Evidence of ungulate species was observed by TEK participants during the field studies along the Edmonton to Hinton Segment. Deer, elk and moose, historically and today, remain a traditional food source of Aboriginal people. Participants described that these ungulates use mineral licks to ingest salt from the mud, to retain water and prevent dehydration. Mineral licks are often found in wetlands and, in general, game trails will lead to mineral licks.

Moose will often travel long distances to find food preferring wetland habitat, but also have the ability to adapt to new habitats when there are limited resources or when industrial and commercial development occurs. During the rutting season in September and October, moose seek low-lying areas with water. Moose travel upwind when looking for food and travel downwind when injured, also seeking out higher ground to pick up scents from the wind to determine where to feed or bed. Participants report that contaminated vegetation is leading to contaminated moose meat, as well as moose that appear thinner and sickly. Participants stated that human health will be affected by animal health since everything is connected and that the health of the animals depends on the health of the land.

Evidence of gray wolf, fox and coyote were identified along the Edmonton to Hinton Segment and included tracks, scat, fur, dens and kill sites. Participants explained that these canines typically den on higher ground, below tree roots (to avoid cave-ins), in remote locations with abundant food sources and water nearby. Sometimes hollowed out trees are used as dens and shelter. Wolf and fox dens generally have two holes, thought to be emergency exits to escape predators. Coyotes and foxes will use their dens for long periods of time and will only abandon the den if disturbed. Abandoned fox dens may sometimes be used by coyotes and badgers. Fox and coyote eat small mammals such as mice, ducklings, duck and grouse. In the winter, the canines will forage for pine needles and dig up food from the ground. Participants noted that a change in weather is coming when coyotes howl. There is a healthy wolf population in the region and participants believe wolves are responsible for the decrease in elk and deer populations. Participants shared that wolves have a varied diet and prey upon geese, ducks, small mammals, plants, moose calves, coyote and even other wolves. On occasion, wolves are known to scavenge other animals' kills. Wolves migrate as a pack and typically hunt alone, except when hunting large animals. The wolf plays a part in Cree tradition representing the hunter and, historically, wolf skins were worn while hunting to sneak up on game.

Participants observed evidence of black bear and grizzly bear along the Edmonton to Hinton Segment, including scat, tracks, dens, chewed or clawed logs and claw marks on trees. Typically, claw marks on trees indicate a den is nearby, since bears do not tend to wander far from where they mark. Clawing trees is a way for bears to mark their territories and sharpen their claws. These claw marks can reach 9 m up the trunk. Black bears will also dig up spots at the bases of trees to mark their territory. Black bears prefer to den on ridges, while grizzlies are found in lower-lying, valley lands of the Rocky Mountains. Grizzly bears travel long distances to hibernate and will mate at higher elevations. Hibernation begins with the first frost in the fall and ends in the spring. Bears are considered sacred animals and while rarely hunted today, bear hides were once traditionally worn while hunting or worn for protection and decorated with feathers and beads.

Participants reported that both beaver and muskrat are reluctant to travel far on land for fear of predators, therefore, they tend to eat berries and vegetation that grow close to the ground and in aquatic environments. Wetlands are ideal habitat for these mammals, since they are close to the water and are abundant in lush vegetation to eat such as young willow and bulrush. Both animals can be dangerous when threatened and will spring up on their tails to bite. Beavers, known in Stoney as “chaba”, will also use their tails to slap the water to warn of predators. Felled trees, teeth marks on the ends of trees and beaver stumps are evidence of beaver habitat. The felled trees are dragged to the beaver dam to establish and build up their dams, often inhabiting the same area for up to 5 years. Participants shared that the length of winter can be predicted by the amount of food beavers collect. Typically, if a beaver dam is torn down in the spring, the beaver will relocate and make a new dam. Fall is thought to be the worst time to tear down a dam, since the beaver will have nowhere to rebuild in time for winter.

Members of the weasel family were identified during the field studies along the Edmonton to Hinton Segment, including marten, mink, wolverine, otter, badger and skunk. These mammals are carnivorous and, on some occasions, scavenge for food. Participants shared that these animals are not trapped very often anymore since fur prices and demand are low. Ideal habitat for these mammals is characterized by larger spruce trees and areas with abundant squirrel activity. Marten fur is the thickest in spring and fall since they tend to prey on grouse and squirrel. Martens and mink prey on beavers as well. Wolverines remain close to forested habitats to hunt small prey. Badgers will make their homes near water if there is abundant prey to hunt, bark to eat and trees for shade.

Signs of squirrel were identified during the field studies along the Edmonton to Hinton Segment, including middens, lodges, holes and nests. Squirrel lodges consist of holes scattered throughout the forest floor, indicating underground tunnels and evidence of the squirrel’s search for pine and spruce cones, seeds and nuts. These small furbearers will stock pile cones, nuts and mushrooms in their tunnels under the snow. Participants reported that squirrels also eat antlers that have been shed on the forest floor since antlers provide needed dietary minerals. Nests are found at the base of trees or high in the branches and are easily recognizable by piles of pine cones nearby. Squirrel middens are piles of leaves and pine, and spruce cone pieces left by squirrels, becoming quite large and indicating the presence of several generations of squirrels. Squirrels also use middens to stockpile food and the length of winter can be predicted by the size of a squirrel’s midden. Squirrels are a traditional food source for Cree people and are eaten when large game is not available. Squirrels are also important for conducting certain traditional ceremonies.

Evidence of rabbit signs, including trails, droppings and fur, were identified during field studies along the Edmonton to Hinton Segment. Moist, open areas near water with soft moss on the ground and tree cover characterize ideal rabbit habitat. Tree cover is used to hide from predators, the lush vegetation for sustenance and the soft, mossy ground to den. Rabbit diets consist of mushrooms, tree bark, roots, grass, Labrador tea, spruce and pine bark, and willow and poplar branches. Rabbits eat tree bark and branches in the winter when vegetation is sparse. Participants shared that watching which mushrooms a rabbit consumes helps to determine which mushrooms are poisonous, since rabbits will not eat poisonous varieties. Rabbits dig their own rabbit holes instead of using existing holes from other animals, protecting the rabbit from predators that may return. Rabbits are preyed on by coyotes and lynx.

Cougar tracks were identified during the field studies along the Edmonton to Hinton Segment and participants reported that cougars travel over a broad range of habitat, including grasslands, water, forest, hills and ridges. Cougars will dig out their dens on the side of ridges and their diet consists of large and small prey. Cougar tracks are heavier in snow than lynx or bobcat and cougars typically do not “drag tail”, unless the snow is deep. When sick or injured, cougars are sometimes spotted near residential areas. Lynx and bobcat signs were also observed and, like cougars, these cats prefer habitats with an ample water supply, grasslands and forest.

Birds of prey, including golden and bald eagle, red-tailed hawk and osprey, were identified during the field studies along the Edmonton to Hinton Segment. Participants reported that these birds tend make their nests high in pine trees along river banks. Eggs will hatch in spring and the young eaglets will leave the nest by mid-July, often returning to the same area where they were hatched, later in life. Osprey and eagle hunt for fish along large watercourses, especially when fish are spawning. Hawks are territorial birds and fiercely defend their territories from other birds like the raven. Hawks prefer to nest near water and open fields ideal for hunting rodents. Not all hawks will migrate in the winter, instead they will take shelter in thick trees. Red-tailed hawks typically make their nests in poplar trees since the trees have strong branches. When a hawk feels threatened, it circles and chirps a warning. Participants reported that the most important bird, for cultural reasons, is the bald eagle. If a dead eagle is found, the bird must be placed in a fire in order for its spirit to rise. While rarely hunted, a ceremony will be held before the eagle is hunted and a bald eagle sighting represents good luck. The eagle symbolizes the thunder bird and the feather can represent the initiation to womanhood or wisdom. Eagle feathers are used as a decorative detail in dance regalia. Different feathers are used for different parts of the regalia. Traditionally, the feathers from only one bird are used so the dress looks uniform. The feathers play an important role in ceremonies and powwows. Eagle bones have customary uses also, for example, the smaller bones under the wing are used for traditional jewellery. The bones are filed down and soaked in bleach. The larger, longer bones are used as whistles for ceremonial gatherings.

Several birds, including ducks and geese species such as woodpecker, owls, swallows, red-winged black birds, wrens, chickadees, Wilson snipes/rain birds, herons and cranes, grouse/bush chicken, Canada geese, mallard ducks, loons and mud hens, were observed during the field studies along the Edmonton to Hinton Segment. Participants reported that the numerous sightings are due to the abundance of watercourses and tree species, including spruce, that make for good nesting sites. “Nee-pin” in Cree means spring and chickadees are called spring birds since their call sounds like “nee-pin”. Participants shared that great horned owls are considered important messengers in Cree culture. Owls do not store food for the winter and, instead, hunt year-round. Grouse or bush chickens nest in muskeg areas and are able to travel effectively through mossy terrain. Their diet includes cranberries, blueberries and gooseberries. Like the partridge, grouse lay their eggs on the ground at the base of trees. Dyed grouse feathers are used in regalia decoration and women will decorate their braids with grouse feathers.

Downy, red-headed and pileated woodpeckers were identified during the field studies along the Edmonton to Hinton Segment and participants report that woodpeckers are important in Cree culture; they are believed to be spiritual messengers. The woodpecker’s diet consist of ants, pine beetles, termites and worms found in a variety of tree species, however, woodpeckers prefer softwood trees like poplar to make their homes.

Detailed TEK methods and results are provided in the Wildlife Technical Report (Volume 5C).

5.10.2 Hargreaves to Darfield Segment

The Hargreaves to Darfield Segment crosses a mosaic of land uses and habitat types, including suburban areas associated with cities and towns, agricultural fields, pasture and forested areas. Agricultural areas are generally located within the vicinity of towns and cities. Forested areas generally consist of Douglas-fir, Engelmann spruce, white spruce, lodgepole pine and trembling aspen with PP encountered on warm dry slopes towards the southern end of the proposed pipeline segment. There are a number of cutblocks in various stages of regeneration along this segment and selective harvesting occurs in many areas. The Hargreaves to Darfield Segment crosses two wildfire burns that occurred within the last 40 years: 1998 (RK 639.6 to RK 647.3); and 2007 (RK 706.4 to RK 706.5) (BC MFLNRO 2013). Wetlands encountered along the Hargreaves to Darfield Segment are generally associated with streams and oxbow lakes, with a small number of shrubby/treed fens and bogs. Terrain varies from flat to gently undulating on wide valley bottoms to moderately undulating hills and steeper slopes along some watercourses and narrow valleys.

The following subsections describe the provincially identified wildlife areas, parks and protected areas, species with special conservation status, and ATK and TEK along the Hargreaves to Darfield Segment.

5.10.2.1 Provincially Identified Wildlife Areas

A summary of provincially identified wildlife areas that are crossed by the Hargreaves to Darfield Segment is provided in Table 5.10-4.

TABLE 5.10-4

PROVINCIALLY IDENTIFIED WILDLIFE AREAS ALONG THE HARGREAVES TO DARFIELD SEGMENT

Wildlife Area	Legal Location	RK Range	Approximate Length (km)
Caribou Range – Wells Gray[1]	b-53-G/83-D-11 to a-42-G/83-D-11	550.0 to 551.6	1.6
	b-41-J/83-D-6 to d-49-J/83-D-3	573.1 to 602.7	29.6
Caribou Range – Groundhog[1]	d-86-K/82-M-14 to c-26-K/82-M-14	629.8 to 635.8	6.0
	a-7-K/82-M-14 to c-65-F/82-M-14	638.8 to 642.3	3.5
	c-24-F/82-M-14 to a-24-F/82-M-14	645.9 to 646.3	0.4
	c-93-C/82-M-14 to b-93-C/82-M-14	649.1 to 649.4	0.3
UWR (u-3-004 for mountain caribou)[2] Located within Wells Gray Caribou Range	a-75-B/83-D-6 to b-75-B/83-D-6	590.0 to 590.2	0.2
	d-26-B/83-D-6 to b-16-B/83-D-6	594.4 to 595.9	1.5
	a-7-B/83-D-6 to a-78-J/83-D-3	597.3 to 600.0	2.7

Notes: 1 Caribou herd ranges defined by BC MOE (2010).
2 UWRs defined by BC MOE (2012a).

5.10.2.2 Parks and Protected Areas

The proposed pipeline corridor is located within the Finn Creek and North Thompson River provincial parks and is adjacent to the Jackman Flats and Blue River Black Spruce provincial parks. The proposed pipeline corridor is not located within or adjacent to an IBA, DUC Priority Area, Migratory Bird Sanctuary, National Wildlife Area, Western Hemisphere Shorebird Reserve, Ramsar wetland or Biosphere Reserve (Bird Studies Canada and Nature Canada 2012, Bureau of the Convention on Wetlands 2013, DUC 2013, Environment Canada 2013n, UNESCO 2012, WHSRN 2013).

5.10.2.3 Species with Special Conservation Status

A desktop review of the potential wildlife species of concern list found that species with special conservation status that are provincially-listed (BC CDC 2013a,b) or federally-listed on Schedule 1 of *SARA* (Environment Canada 2013o) or by COSEWIC (2013a) that have potential to occur along the Hargreaves to Darfield Segment are listed in Table 5.10-5. A search of the BC CDC records identified occurrences of provincially and federally-listed wildlife species of concern (BC CDC 2013b) (Table 5.10-5).

Notes: Definitions of Status Designations are provided in Appendix C of the Wildlife Technical report of Volume 5C. Federal ratings are current to November 2013.

1 Provincial (S) rank assigned by the BC CDC (2013a).

2 Species listed under the BC *Wildlife Act* (BC CDC 2013a).

TABLE 5.10-5 Cont'd

3 Provincial Red and Blue designations assigned by BC CDC (2013b).

4 Conservation goals and priorities established under the BC Conservation Framework (BC MOE 2009b,c).

5 Species listed under Schedule 1 of *SARA* (Environment Canada 2013o).

6 Species listed under COSEWIC (2013a).

5.10.2.4 Traditional Ecological Knowledge

During the field studies along the Hargreaves to Darfield Segment, participants described that interconnectedness exists in the forest between all elements of the ecosystem, including humans. Most wildlife will spend most of their time in the hills and mountains, moving to lower elevations if in need of food.

In September, large game like moose, elk and deer are mating. Large game will be aggressive during the fall rut and they will also be aggressive during the spring when their offspring are born. Before the fall rut, bull elk, moose and deer can be seen with velvet hanging off of their antlers. Mineral licks are used by ungulates like sheep, goats, elk and deer. Participants shared that Elders will not usually hunt at salt licks since it is unfair to hunt easy prey. Predators will hunt at mineral licks which are usually found in soils with heavy clay and calcium content. Animals will frequent mineral licks all year long.

Participants reported that the valley along the North Thompson River is a wildlife corridor. Animals make dens underground, in hollow trees and under boulders. Animals that use dens and wildlife trees include bats, chipmunks, owls, squirrels, flying squirrels, badgers, woodpeckers, bears, rabbits, hares, voles, porcupines, lynx, wolves, coyotes, wolverines and martens. Scaly bark is an indication of a wildlife tree, since scaly bark is good for bats and perching birds. Perching trees, used by hawks and owls, have more branches and leaves than wildlife trees. It is possible to identify an active cavity nest by the presence of whitewash around the hole. Birds often try to lead predators away from their nests by pretending that they are injured.

Shrubs, bark, willow, spruce, wild rhubarb, fireweed, skunk cabbage and lilies are eaten by moose. Moose eat the bark and cambium of trees like balsam fir. Foliage that has been grazed upon by moose can be identified by the height and roughness of foliage chewed. The amount of grazing in an area can indicate whether moose use the area regularly. Moose will not normally eat smaller aspen, however, they will when there is not much else to eat. A participant reported that moose tend to go to high ground during the day or during the summer since it is cooler and at dusk they come down for water. Other participants reported that moose will rest near creeks to cool down and that they move to lower elevations during the winter. Moose would not likely bed in an open area, preferring, instead, areas like wetlands for water and riparian vegetation, like willow and tall grasses, because wetter ground conditions also inhibit predators. The open trees make a good location for the animals to rest out of the sun during summer. In the winter, the trees shade them from snow. Snow accumulation is notably less in areas with green trees. Participants noted that man-made paths and rights-of-way can be good corridors for wildlife like moose, however, moose would only use such clearings for travel if there was not a waterbody or wetland nearby. Calving moose also prefer tall grass near swamps to hide from predators and to access water for the calves. Moose is a traditional source of food for Aboriginal communities that is still consumed today.

White-tailed deer and mule deer were identified during the field studies along the Hargreaves to Darfield Segment. Participants reported that there used to be more white-tailed deer than mule deer in this region, however, this dynamic has since reversed. Good deer (and elk) habitat will have abundant plants and shrubs for browsing, including kinnikinnick, rosehips, fireweed, aspen tree tips and thimbleberry leaves. Both kinds of deer, as well as elk, are traditional food sources for Aboriginal communities. Deer will rub their antlers against trees and will rattle trees to alert other males nearby. Rubbing trees leaves an identifying scent on them. Mule deer antlers fork, while white-tailed deer antlers have all points coming off of one branch. Antlers can be used by people to dig up roots like potatoes, carrots and wild ginger. Deer will travel along slopes and challenging terrain to avoid predators. Slopes allow for a better line-of-sight and prevent predators from attacking from behind.

Participants reported that the local caribou population has decreased since the use of snowmobiles, industrial and urban development, overhunting and climate changes have increased over time. Lands along the Hargreaves to Darfield Segment were once an important part of caribou ranges. Mountain caribou would travel in small herds and, in the winter, remain in their alpine habitat to eat moss, descending from the mountains in the summer. When caribou eat frecklepelt lichen, their meat will be very tender. Participants also reported that caribou would not be found near Valemount, however, there are many different herds located near Jasper. Large herds of caribou have not been seen in the Valemount region for decades. The valley crossed at RK 669.3 and surrounding lands was at one time populated by caribou. In the 1930s and 1940s, caribou were so abundant that traffic had to be stopped when caribou were crossing. Participants commented that herds in this valley now have only 8 to 10 individuals.

During the field studies along the Hargreaves to Darfield Segment, participants explained that bears are constantly on the move throughout their extensive ranges. Bears may travel along existing rights-of-way, preferring open areas during spring and summer when berries are abundant. Good habitat for bears will be well away from human activity. Lands with abundant ground cover provide bears, especially sows and their young, with protection from the elements and predators. While bears are omnivores, most of their meat-eating is opportunistic, more often consuming berries, insects, grass, fish and grubs. Bears prefer eating berries to pulling apart rotten logs to find grubs. Participants shared that bears play an important role in local culture and are sacred animals.

Carnivorous predators identified during the field studies along the Hargreaves to Darfield Segment include coyotes, wolves, cougars and other large cats. Coyotes prefer open lands along the banks of watercourses and will frequent the banks to communicate with other coyotes since the water carries their voices farther. Participants reported that up until the 1940s, wolves were culled to protect livestock and humans. Wolves are nomadic and travel according to the season and available game. Wolves run in packs with a single alpha male and pack sizes depend on prey abundance. Wolves will eat deer and sometimes even small bears. Cougars are unlikely to hunt where the forest is quite open and where there is not much cover, avoiding human activity and preferring to live high in the mountains. Cougars will only venture into more populated and developed areas if food is scarce elsewhere.

Many small and medium-sized mammals were identified by participants during the field studies along the Hargreaves to Darfield Segment and most were reported to be hunted by local Aboriginal communities. Porcupine quills can be used to make jewellery such as earrings and necklaces, artisanal works and ceremonial garb. However, participants reported that porcupines are not very common along this segment. Rabbit meat is a source of food and the fur is used for traditional purposes. Squirrels are a traditional food source and the fur is also used. Squirrels will eat songbird eggs and young nestlings, mushrooms and apples. Ground squirrels often den close to cedar or hemlock roots. A sloping, open field is good habitat for ground squirrels since the slope would allow for drainage of their tunnel systems.

Many bird species were identified by participants during the field studies along the Hargreaves to Darfield Segment including woodpeckers, flickers, owls and eagles. Woodpeckers are compulsive birds that will knock and drill holes on the same tree for years. A pileated woodpecker will call out to signal that humans are approaching. Flickers have distinct orange under their wings and fly in a “flitty” manner. Owls eat voles, birds and bats and are thought to be messengers of death. Characteristics of golden eagles and bald eagles were described by participants; eagles eat fish, gophers and ground hogs and tend to nest in big trees, either living or dead, making their nests out of sticks and returning to the same nest for many years. Participants report that the local population of eagles is growing. Eagles represent protection to local communities and Aboriginal people will carry eagle feathers for this reason.

Blue, ruffled and willow grouse were also identified by participants during the field studies along the Hargreaves to Darfield Segment. The sound of a blue grouse drumming can be differentiated from a ruffled grouse drumming by the way the blue grouse starts drumming slowly and the sound can be felt in the heart. Grouse drum to attract females and to defend and identify their territory. Willow grouse make a thumping noise. Participants reported that this thumping noise may be used to scare predators since the thumping is heard before the bird takes flight.

Detailed TEK methods and results are provided in the Wildlife Technical Report (Volume 5C).

5.10.3 Black Pines to Hope Segment

The Black Pines to Hope Segment crosses a mosaic of land uses and habitat types, including suburban areas associated with cities and towns, agricultural fields (*i.e.*, cultivation and hay fields), pasture, grasslands and forested areas. The grasslands north and south of Kamloops show signs of human disturbance in the form of trails, access roads and cattle grazing. Forested areas are generally dominated by Douglas-fir and PP with open, grassy understories, particularly in PP stands. Areas of PP forest also contain large open grassland areas interspersed with big sage brush. Selective forest harvest is common along this segment, as evidenced by old stumps on the forest floor and sporadic large veteran Douglas-fir trees. The Black Pines to Hope Segment crosses three wildfire burns that occurred within the last 40 years: 1987 (RK 830.1 to RK 830.7); 2008 (RK 826.5 to RK 826.6); and 2009 (RK 826.3 to RK 826.7) (BC MFLNRO 2013). Wetlands encountered along the Black Pines to Hope Segment are generally associated with streams and oxbow lakes, with a number of shrubby/treed fens and bogs. Terrain along the proposed pipeline segment varies from flat to gently undulating in large valley bottoms to moderately and steeply undulating hills through the grasslands and forested areas north and south of Kamloops. Steeper slopes are encountered along some watercourses and narrow valleys (*e.g.*, Coquihalla Valley).

The following subsections describe the provincially identified wildlife areas, parks and protected areas, species with special conservation status, and ATK and TEK along the Black Pines to Hope Segment.

5.10.3.1 Provincially Identified Wildlife Areas

A summary of provincially identified wildlife areas in relation to the Black Pines to Hope Segment is provided in Table 5.10-6.

TABLE 5.10-6

PROVINCIALLY IDENTIFIED WILDLIFE AREAS ALONG THE BLACK PINES TO HOPE SEGMENT

Wildlife Area	Legal Location	RK Range	Approximate Length (km)
UWR (u-3-003 for mule deer)[1]	c-96-D/92-I-8 to b-86-D/92-I-8	892.0 to 893.4	1.4

Notes: 1 UWRs defined by BC MOE (2012a).
2 WHAs defined by BC MOE (2005a).

5.10.3.2 Parks and Protected Areas

The proposed pipeline corridor is located within Lac du Bois Grasslands Protected Area and the Coquihalla Summit Recreation Area and is adjacent to the Coldwater River, Coquihalla River and Coquihalla Canyon provincial parks. It is also located within the Douglas Lake Plateau IBA (BC172) (Bird

Studies Canada and Nature Canada 2012) and the DUC Level 3 Priority Landscape, Eastern Boreal Forest, which encompasses areas rich in wetlands, lakes, ponds, rivers, and streams and supports breeding, migrating, mounting, and staging waterfowl (DUC 2013). The proposed pipeline corridor is not located within or adjacent to a Migratory Bird Sanctuary, National Wildlife Area, Western Hemisphere Shorebird Reserve, Ramsar wetland or Biosphere Reserve (Bureau of the Convention on Wetlands 2013, Environment Canada 2013n, UNESCO 2012, WHSRN 2013).

5.10.3.3 Species with Special Conservation Status

A desktop review of the potential wildlife species of concern list found that species with special conservation status that are provincially-listed (BC CDC 2013a,b) or federally-listed on Schedule 1 of *SARA* (Environment Canada 2013o) or by COSEWIC (2013a) that have potential to occur along the Black Pines to Hope Segment are listed in Table 5.10-7. A search of the BC CDC records identified occurrences of provincially and federally-listed wildlife species of concern (BC CDC 2013b) (Table 5.10-7).

Notes: Definitions of Status Designations are provided in Appendix C of the Wildlife Technical report of Volume 5C. Federal ratings are current to November 2013.

1 Provincial (S) rank assigned by the BC CDC (2013b).

2 Species listed under the BC *Wildlife Act* (BC CDC 2013b).

3 Provincial Red and Blue designations assigned by BC CDC (2013b).

4 Conservation goals and priorities established under the BC Conservation Framework (BC MOE 2009a,b).

5 Species listed under Schedule 1 of *SARA* (Environment Canada 2013o).

6 Species listed under COSEWIC (2013).

5.10.3.4 Traditional Ecological Knowledge

During the field studies along the Black Pines to Hope Segment, participants identified wildlife signs including tracks, browse and scat of ungulates such as mule deer, white-tailed deer and moose. Moose and deer are present in the hills near the City of Merritt, BC. The hills on the north side of Nicola Lake are considered excellent habitat since there is good foraging with the presence of willow and rose bushes, water sources and a healthy, wooded landscape. In the past, white-tailed deer were less common than mule deer, however, white-tailed deer are starting to move in from the east. White-tailed deer carry a disease or parasite that affects mule deer, which in turn has negatively affected the mule deer population. Elk are more common towards Brooksmuir. Participants reported that the proposed pipeline corridor encounters lands previously disturbed by power lines, fibre optic cables and other pipeline rights-of-way, and that wildlife in the region have already adjusted. There is a lot of browse for moose and deer to eat, like alder, grasses and willow, and the existing rights-of-way are like cleared paths which encourage wildlife movement. Good wildlife habitat will include trees like Douglas-fir, trembling aspen, spruce and lodgepole pine with a source of water nearby, as well as a generally healthy ecosystem with few pine beetles or spruce bud worms and ample vegetation and berry plants.

Game trails, primarily used by moose, deer and bear, were identified along the Black Pines to Hope Segment. Game trails are often used to access existing rights-of-way, watercourses and rest or bedding areas. Bear claw marks were identified on trees during the field studies, some recent and some several years old. The size of the marks is an indicator of the size of the bear that created them. Participants described how cubs cannot gouge the tree, but can scamper up a tree. Participants noted that in the past, bears likely foraged for berries in nearby farmers' fields, however, the installation of an electric fence has likely caused bears to retreat to the hills. Abundant blackberry bushes that grow at higher elevations and cherry trees that grow in the valleys provide food sources for black bears. Bears also fish for coho salmon from small watercourses in the region. Good habitat for bears will be close to water, berries and a path. Good grizzly bear habitat was identified near Juliet Creek due to the presence of salmon, the abundance of denning habitat and berry plants, and minimal human presence. TEK participants have noted that over the past 20 years, there has been decline in the regional grizzly population and they attribute this to a decline in salmon. Bears are moving further south and west for food sources at higher elevations. Bears once frequented the Fraser and Thompson rivers, however, participants believe that increased human presence in the region prevent bears from returning.

Coyote, wolf and cougar signs were identified by participants during field studies along the Black Pines for Hope Segment. Participants reported that wolves were once the dominant predator in the region, but have since been hunted nearly to extinction and are only recently beginning to show signs of rebounding. Coyotes were traditionally trapped for their fur and are central figures in many traditional stories of Aboriginal communities in BC.

Participants reported that marten, otters, beavers, muskrat, lynx and rabbits are commonly observed along the Black Pines to Hope Segment and that all of these animals are traditionally harvested. These fur-bearing animals are used for clothing and other accessories. Beaver dams and habitat are prevalent along the Nicola River and its smaller tributaries. Participants noted that beavers will eat a varied diet and are traditionally trapped by Aboriginal communities. Participants also reported that beavers are a nuisance since they block salmon from migrating upstream. Groundhog holes were identified along Mine Creek and participants report that groundhogs will live anywhere with other groundhogs in colonies. Groundhogs are common animals and are not traditionally hunted by communities in this region.

Birds are important to communities along the Black Pines to Hope Segment. Birds indicate when spring has arrived, whereby eagles arrive first, ducks will follow as will cranes. Once cranes have arrived, it is confirmed that spring has started. Grouse are plentiful and wild grouse were observed and heard by participants during the field studies. Ruffled, blue and spruce grouse are found in the forest while sharp-tailed grouse prefer grasslands. Grouse are sometimes hunted by Aboriginal communities in the fall.

Detailed TEK methods and results are provided in the Wildlife Technical Report (Volume 5C).

5.10.4 Hope to Burnaby Segment

There is a high level of anthropogenic disturbance along the Hope to Burnaby Segment, which is characterized by agricultural fields and urban, residential and industrial complexes. Throughout this area are residual pockets of suitable habitat for several species, which are of increasing importance with the level of disturbance. Forested areas typically have open understories and are dominated by Douglas-fir, western hemlock and western redcedar. Riparian areas are dominated by black cottonwood. Wetlands encountered along this segment are generally associated with streams and oxbow lakes, with a number of shrubby/treed fens and bogs. The Hope to Burnaby Segment follows south of the Fraser River and the terrain is generally flat with some undulating hills.

The following subsections describe the provincially identified wildlife areas, parks and protected areas, species with special conservation status, and ATK and TEK along the Hope to Burnaby Segment.

5.10.4.1 Provincially Identified Wildlife Areas

The Hope to Burnaby Segment is not located within or adjacent to a provincially identified wildlife area (BC MOE 2005a, 2010, 2012a).

5.10.4.2 Parks and Protected Areas

The proposed pipeline corridor is located within the F.H. Barber Provincial Park from RK 1062.8 (d-62-B/92-H-5) to RK 1062.8 (d-62-B/92-H-5), which is situated in the CWH BGC Zone with vegetation representative of the undisturbed Fraser flood plain and provides habitat for birds and small mammals (BC MOE 2012b). The Hope to Burnaby Segment is also located within the DUC Priority 2 Landscape, BC Coastal Areas and Estuaries, which provides important migration and winter habitat that supports a wintering population of over one million waterfowl (DUC 2013). The proposed pipeline corridor is not located within or adjacent to an IBA, Migratory Bird Sanctuary, National Wildlife Area, Western Hemisphere Shorebird Reserve, Ramsar wetland or Biosphere Reserve (Bird Studies Canada and Nature Canada 2012, Bureau of the Convention on Wetlands 2013, Environment Canada 2013n, UNESCO 2012, WHSRN 2013).

The Hope to Burnaby Segment is located within or adjacent to several regional parks and locally important areas, including Cheam Lake Wetlands Regional Park, Mountain View Conservation and Breeding Centre, Sumas Mountain Interregional Park and Surrey Bend Regional Park (City of Abbotsford 2012, FVRD 2008b, Metro Vancouver and City of Surrey 2010, Mountain View Conservation and Breeding Centre 2013).

5.10.4.3 Species with Special Conservation Status

A desktop review of the potential wildlife species of concern list found that species with special conservation status that are provincially-listed (BC CDC 2013a,b) or federally-listed on Schedule 1 of *SARA* (Environment Canada 2013o) or by COSEWIC (2013a) that have potential to occur along the Hope to Burnaby Segment are listed in Table 5.10-8. A search of the BC CDC records identified occurrences of provincially and federally-listed wildlife species of concern (BC CDC 2013b) (Table 5.10-8).

Northern red-legged frog	S3S4[1] Blue[3] Priority 1[4] Goal 2[4]	Special Concern[5,6]
Northern rubber boa	S4[1] Yellow[3] Priority 1[4] Goal 2[4]	Special Concern[5,6]
Oregon spotted frog	S1[1] Red[3] Priority 1[4] Goal 1,3[4]	Endangered[5,6]
Pacific giant salamander	S2[1] Red[3] Priority 1[4] Goal 3[4]	Threatened[5,6]
Painted turtle, Pacific Coast population	S2[1] Red[3] Priority 2[4] Goal 3[4]	Endangered[5,6]
Western toad	S3S4[1] Blue[3] Priority 2[4] Goal 2[4]	Special Concern[5,6]
INVERTEBRATES		
Dun skipper	S3[1] Blue[3] Priority 2[4] Goal 2[4]	Threatened[5,6]
Monarch	S3B[1] Blue[3] Priority 2[4] Goal 2[4]	Special Concern[5,6]
Oregon forestsnail	S1S2[1] Red[3] Priority 1[4] Goal 3[4]	Endangered[5,6]

Notes: Definitions of Status Designations are provided in Appendix C of the Wildlife Technical report of Volume 5C. Federal ratings are current to November 2013.

1 Provincial (S) rank assigned by the BC CDC (2013a).

2 Species listed under the BC *Wildlife Act* (BC CDC 2013a).

3 Provincial Red and Blue designations assigned by BC CDC (2013b).

4 Conservation goals and priorities established under the BC Conservation Framework (BC MOE 2009b,c).

5 Species listed under Schedule 1 of *SARA* (Environment Canada 2013o).

6 Species listed under COSEWIC (2013a).

5.10.4.4 Traditional Ecological Knowledge

Participants identified evidence of deer along the Hope to Burnaby Segment, including tracks, scat, beds, browse and game trails, reporting that deer tend to be wide-ranging animals, adaptable and already accustomed to human disturbance due to the existing highways, power lines and pipeline rights-of-way within the proposed pipeline corridor. Deer are most commonly found on lands with a water source nearby and plenty of vegetative cover to provide shelter from the weather and predators. Deer can move quietly though tall grass due to their small stature, following the same trails each year and showing their young the same trails, unless the trails become disturbed by humans or environmental changes such as erosion. Deer will eat grasses and shrubs, such as alfalfa, and wild mushrooms, such as pine mushrooms. Deer are commonly hunted for food and hides.

Evidence of black bears were also observed during the field studies along the Hope to Burnaby Segment, including tracks, scat, claw marks on trees, beds and trails. Sawdust under a bear-dug log indicates that the dig is relatively fresh because sawdust will eventually wash away over the course of the year. Black bears dig at stumps for grubs, ants and termites in the early spring following hibernation and also feed on berries and grasses in the spring and early summer, and salmon during the late summer and fall. Participants reported that bears are seen more commonly near their communities; an indication that they are getting hungrier. Bear claws are commonly used as regalia in smokehouses, typically taken from a found carcass rather than through hunting. Grizzly bear tracks and scat were also identified by participants and it was reported that bears are likely using the existing right-of-way for habitat and food sources.

Cougar tracks, scat and appropriate habitat were observed by participants during the field studies along the Hope to Burnaby Segment. Cougars spend their summers in alpine environments, migrating to lower elevations during the winter. Cougars are wide-ranging mammals that are able to travel more than 30 km in a day and existing rights-of-way function as travel corridors. Signs of coyote were also observed and participants noted that coyotes appear to be using an existing fibre optic cable right-of-way as a travel corridor, evidenced by scat along the right-of-way. An inactive coyote den might have grass in the tunnel passage and, generally, when humans find a coyote's den, the animal will move for the safety of the pups. The coyote is a central character in the stories, mythology and beliefs of the local cultures and is known to be good and bad; a trickster.

Birds of prey were identified during the field studies including eagle, osprey and red-tailed hawk. Eagle and hawk feathers are used in smokehouse ceremonies and eagle feathers and claws are used for decorations and drumsticks. Feathers are also used to make headdresses for powwow dancing and hand fans and are used in sweetgrass ceremonies for cleansing. Eagle feathers are said to be good luck, whereas white owls are thought to mean bad luck. Participants reported that hawks will abandon their nests and even their young if there is excessive noise pollution. Other birds identified by participants during the field studies along the Hope to Burnaby Segment include woodpeckers, turkey vultures, grouse and a hummingbird. Woodpeckers are not a common sight or sound throughout the region and are heard only a few times a year.

Detailed TEK methods and results are provided in the Wildlife Technical Report (Volume 5C).

5.10.5 Burnaby to Westridge Segment

The Burnaby to Westridge Segment is characterized by residential neighbourhoods and industrial complexes within Burnaby. There is a small residual forest stand that is dominated by western redcedar, western hemlock and Douglas-fir.

The following subsections describe the provincially identified wildlife areas, parks and protected areas, species with special conservation status, and ATK and TEK along the Burnaby to Westridge Segment.

5.10.5.1 Provincially Identified Wildlife Areas

The Burnaby to Westridge Segment is not located within or adjacent to a provincially identified wildlife area (BC MOE 2005a, 2010, 2012a).

5.10.5.2 Parks and Protected Areas

The proposed pipeline corridor is located within the English Bay and Burrard Inlet IBA (BC020) from RK 3.2 (b-47-D/92-G-7) to RK 3.6 (d-47-D/92-G-7), which includes the shores of Burrard Inlet and English Bay. The IBA was designated primarily to protect western grebe, Barrow's goldeneye, surf scoter and great blue heron (*fannini* subspecies). The area also provides nesting habitat for pelagic and double-crested cormorants, osprey and bald eagle and the purple martin is commonly found nesting in nest-boxes along the shores (Bird Studies Canada and Nature Canada 2012). The proposed pipeline corridor is also located within the DUC Priority 2 Landscape, BC Coastal Areas and Estuaries, which provides important migration and winter habitat that supports a wintering population of over one million waterfowl (DUC 2013). The Burnaby to Westridge Segment is not located within or adjacent to a provincial park or protected area, Migratory Bird Sanctuary, National Wildlife Area, Western Hemisphere Shorebird Reserve, Ramsar wetland or Biosphere Reserve (BC MOE 2012b, Bureau of the Convention on Wetlands 2013, Environment Canada 2013n, UNESCO 2012, WHSRN 2013). The Burnaby to Westridge Segment is located within the Burnaby Mountain Conservation Area (City of Burnaby 2013).

5.10.5.3 Species with Special Conservation Status

A desktop review of the potential wildlife species of concern list found that species with special conservation status that are provincially-listed (BC CDC 2013a,b) or federally-listed on Schedule 1 of *SARA* (Environment Canada 2013o) or by COSEWIC (2013a) that have potential to occur along the Burnaby to Westridge Segment are listed in Table 5.10-9. A search of the BC CDC records identified occurrences of provincially and federally-listed wildlife species of concern (BC CDC 2013b) (Table 5.10-9).

TABLE 5.10-9

SPECIES WITH SPECIAL CONSERVATION STATUS – BURNABY TO WESTRIDGE SEGMENT

Common Name	Provincial Designations	Federal Designations
BIRDS		
American bittern	S3B[1] Blue[3] Priority 2[4] Goal 2[4]	--
Band-tailed pigeon	S3S4B[1] Blue[3] Priority 2[4] Goal 2[4]	Special Concern[5,6]
Barn owl	S3[1] Blue[3] Priority 2[4] Goal 2[4]	Special Concern[5] Threatened[6]
Barn swallow	S3S4B[1] Blue[3] Priority 2[4] Goal 2[4]	Threatened[6]
California gull	S3B[1] Blue[3] Priority 4[4] Goal 3[4]	--
Common nighthawk	S4B[1] Yellow[3] Priority 2[4] Goal 2[4]	Threatened[5,6]
Double-crested cormorant	S3S4B[1] Blue[3] Priority 2[4] Goal 2[4]	--

Monarch	S3B[1] Blue[3] Priority 2[4] Goal 2[4]	Special Concern[5,6]

Notes: Definitions of Status Designations are provided in Appendix C of the Wildlife Technical report of Volume 5C. Federal ratings are current to November 2013.

1 Provincial (S) rank assigned by the BC CDC (2013a).

2 Species listed under the BC *Wildlife Act* (BC CDC 2013a).

3 Provincial Red and Blue designations assigned by BC CDC (2013b).

4 Conservation goals and priorities established under the BC Conservation Framework (BC MOE 2009b,c).

5 Species listed under Schedule 1 of *SARA* (Environment Canada 2013o).

6 Species listed under COSEWIC (2013a).

5.10.5.4 Aboriginal Traditional Knowledge

Available ATK related to wildlife along the Hope to Burnaby Segment is limited. However, concerns and recommendations identified on other proposed projects within the Tsleil-Waututh Nation traditional territory include concerns about the terrestrial effects resulting from oil tankers traveling off the coast (Northern Gateway Pipelines Partnership Ltd. 2010).

5.11 Species at Risk

Five fish species that are listed under Schedule 1 of *SARA* are found in the Aquatics RSA. White sturgeon (Upper Fraser River population) is Endangered (Environment Canada 2013o) and is found in the Aquatics RSA along the Hargreaves to Darfield Segment. The Hope to Burnaby Segment contains four *SARA*-listed fish species: green sturgeon (Special Concern); Salish sucker (Endangered); Nooksack dace (Endangered); and westslope cutthroat trout (Special Concern) (Environment Canada 2013o). However, westslope cutthroat trout are introduced to drainages in the Hope to Burnaby Segment and, therefore, are not considered to be a conservation concern within the Aquatics RSA. Two fish species that are listed by COSEWIC, lake sturgeon (Endangered) and bull trout (Threatened [Saskatchewan-

Nelson population] and Special Concern [Western Arctic population]) are found in the Aquatics RSA in the Edmonton to Hinton Segment (COSEWIC 2013a). The Aquatics RSA in the Hargreaves to Darfield Segment contains three fish species listed by COSEWIC: bull trout (Special Concern); mountain sucker (Special Concern); and interior Fraser River coho salmon (Endangered) (COSEWIC 2013a). One COSEWIC-listed species (bull trout [Special Concern] and interior Fraser River coho salmon [Endangered]) are found in the Aquatics RSA in the Black Pines to Hope Segment (COSEWIC 2013a). The Aquatics RSA in the Hope to Burnaby and Burnaby to Westridge segments contains five fish species listed under COSEWIC (2013a): bull trout (Special Concern); Lower Fraser River population of white sturgeon (Threatened); mountain sucker (Special Concern); eulachon (Endangered); and Cultus Lake population of sockeye salmon (Endangered). Federal ratings are current to November 2013. See Section 4.1.4 of the Fisheries (British Columbia) Technical Report of Volume 5C for additional details about the fish species at risk in the Aquatics RSA.

A search of the ACIMS and BC CDC databases identified two species (Mexican mosquito fern and Haller's apple moss) listed as Threatened under COSEWIC and *SARA* (COSEWIC 2013a, Environment Canada 2013o) in the Vegetation RSA along the Hargreaves to Darfield Segment. Mexican mosquito fern was also potentially observed during the 2013 vegetation surveys within the Hargreaves to Darfield Segment, with identification to be confirmed (see Section 9.0 Supplemental Studies for details). No other COSEWIC or *SARA*-listed species were identified by ACIMS or the BC CDC, or observed during the 2013 vegetation surveys along the proposed pipeline corridor. Federal ratings are current to November 2013. Additional details on the results of the 2013 vegetation surveys are provided in Section 6.9 and in the Vegetation Technical Report of Volume 5C.

Federally-listed wildlife species (*i.e.*, COSEWIC or *SARA* Schedule 1 designation) identified as having potential to occur along the proposed pipeline segments (based on known ranges and preferred habitat availability) are discussed in Section 5.10. Species at risk identified as indicators for the Project include grizzly bear, woodland caribou, short-eared owl, rusty blackbird, flammulated owl, Lewis's woodpecker, Williamson's sapsucker, western screech-owl, great blue heron (*fannini* ssp.), spotted owl, common nighthawk, northern goshawk (*laingi* ssp.) and olive-sided flycatcher. In addition, many of the habitat-based species communities and species groups identified as indicators included species at risk. Federal ratings are current to November 2013.

5.12 Line Facilities

The locations of line facilities (*e.g.*, automated MLBV, scraper traps) will be located within the permanent easement, the setting of which has been described in Sections 5.1 to 5.11. Many automated MLBVs will be accessed by existing access roads, however, permanent access roads may be required at yet unspecified locations.

5.13 Reactivated Pipeline Segments

The reactivated segments from Hinton to Hargreaves and Darfield to Black Pines parallel the existing active TMPL system. The existing TMPL easement through Jasper National Park and Mount Robson Provincial Park is 6.1 m and 18 m wide, respectively. Outside the parks, the existing right-of-way along the two segments is generally 18 m wide. Surface disturbance along the reactivated segments will be limited to locations where automated MLBVs will be installed, where existing valves will be automated or where integrity digs are conducted.

5.13.1 Hinton to Hargreaves Segment

The existing Hinton to Hargreaves pipeline segment extends from NW 33-49-26 W5M (RK 339.4) to 20-B/083-E-3 (RK 489.6). Surface disturbance along this segment is anticipated to be confined to the existing easement and will be limited to locations where automated MLBVs will be installed, where existing valves will be automated or where integrity digs are conducted. These locations have yet to be determined. Table 5.13-1 provides a summary of the biophysical elements and considerations for the reactivation of the Hinton to Hargreaves Segment pursuant to Guide A.2.4 as well as Table A-2 of the NEB *Filing Manual*.

TABLE 5.13-1

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE HINTON TO HARGREAVES REACTIVATED SEGMENT

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The eastern portion of the Alberta side of the Hinton to Hargreaves Segment is located within the Southern Alberta Uplands Physiographic Region, which is characterized by hummocky terrain, rolling uplands, gently undulating terraces and incised river valleys (Pettapiece 1986, Natural Regions Committee 2006a). • Entering Jasper National Park and in BC, the Hinton to Hargreaves Segment is located within the Rocky Mountains Physiographic Region, which is characterized by structurally-controlled moderately wide valleys surrounded by rugged alpine mountains featuring relict glacial landforms (Holland 1976, Pettapiece 1986). • The Hinton to Hargreaves Segment is underlain by sedimentary rock including sandstones, siltstones, shales, dolomite and limestone (BC ILMB 2013b, Hamilton *et al.* 1999). • Surficial materials along much of the Hinton to Hargreaves Segment are characterized by colluvial, fluvial and till deposits, and bedrock (BGC Engineering Inc. 2013a, Pettapiece 1986). • There are no areas of permafrost along the Hinton to Hargreaves Segment (refer to Section 5.1.1). • Rock falls and debris avalanches have the potential to occur along the Hinton to Hargreaves Segment, particularly along narrow areas of the Fraser River valley in BC, where snow avalanches may also occur. • The earthquake ground shaking hazard is low on lands crossed by the Hinton to Hargreaves Segment. PGA is between 0.1 g and 0.2 g at a 1:2475 APE (BGC Engineering Inc. 2013c). The segment crosses a zone of suspected post-glacial fault activity within the Rocky Mountain Trench, where the historical earthquake record shows clusters of small to moderate magnitude (up to magnitude 6) earthquakes. The largest of these include a 6 magnitude earthquake near Valemount in 1918 and a 5.6 magnitude earthquake near Prince George in 1986 (Halchuk 2009, Lamontagne *et al.* 2007). • Topography along the segment ranges from gentle to steep slopes along the valley bottom and lower valley slope areas. • Elevations range from 1,110 m asl at the Hinton Pump Station to 990 m asl in the Athabasca River valley and to 1,060 m asl at the Jasper townsite. The Yellowhead Pass lies at an elevation of 1,140 m and the Hargreaves tie-in lies at 860 m asl. • In Alberta, the reactivated segment is located within the Montane Natural Subregion (Natural Regions Committee 2006a). A description of the climate for the Montane Natural Subregion is provided in Section 5.1.1. • In BC, the reactivated segment is predominantly in the SBS BGC Zone, with the westernmost approximately 7 km of the segment located within the ICH BGC Zone (Meidinger and Pojar 1991). A description of the climate for both BGC zones is provided in Section 5.1.2. • The following meteorological data were obtained from an Environment Canada meteorological station (3053520) in Jasper, Alberta (Environment Canada 2013a). The data was taken approximately 8 km south-southwest of Jasper Pump Station. – Average monthly rainfall for Jasper is 25.4 mm and the average monthly rainfall from June to August is 59.6 mm. In August of 1969, Jasper recorded its highest daily rainfall of 107.7 mm, which is above the monthly average of 64.6 mm for the month of August. – Average monthly snowfall for Jasper is 10 cm and the average monthly snowfall from November to February is 21 cm. In February of 1948, Jasper recorded its highest daily snowfall of 51.6 cm, well above the 14.7 cm average for the month of February. – Average daily temperature for Jasper is 3.6°C, with the warmest month in July, averaging 15.2°C and coolest month in December, averaging -9.1°C. In July of 1941, Jasper experienced its warmest day of 36.7°C and in January of 1935, its coolest day at -46.7 °C. – No major tornadoes or hailstorms have been recorded in the vicinity of the segment (NRCan 2010b,c).
Soil and Soil Productivity	• The existing Hinton to Hargreaves Segment travels through Jasper National Park and Mount Robson Provincial Park. Surface disturbance to soils caused by reactivating this segment is expected to be confined to the existing easement and will be limited to locations where valves will be installed or automated, or where integrity digs are conducted. • A soil survey along the existing Hinton to Hargreaves Segment was conducted in 2005 for the TMX Anchor Loop Project. Soils along the existing pipeline segment in Alberta are very strongly to extremely calcareous and have a substantial depth of topsoil while soils in the eastern portion of Jasper National Park have thinner topsoil depths but are still very strongly to extremely calcareous. Calcareous Melanic Brunisols developed on eolian veneers and blankets as well as Calcareous Orthic and Cumulic Regosols developed on fluvial fans occur throughout the eastern portion of the existing pipeline segment. These soils occur in rapidly to imperfectly drained positions. Orthic and Eutric Brunisols with little or no topsoil (Ah, Ahe, or Ap horizons) and developed on glaciofluvial sands and gravels, glaciolacustrine silts, fluvial fans and coarse-textured till materials are also prevalent along the existing pipeline segment. These soils mainly occur in the central and western portions of Jasper National Park and eastern portion of Mount Robson Provincial Park. Carbonates were detected at 50 cm to 80 cm below the surface in some of these soils (Mentiga 2005). • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.

TABLE 5.13-1 Cont'd

Environmental Elements	Summary of Considerations
Water Quality and Quantity	• The Hinton to Hargreaves Segment lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. • Flow regimes along this segment are generally dominated by snowmelt, with some influence from shrinking glaciers. Over winter months, precipitation stored as snowpack accumulates. During spring, increased temperatures combined with rainfall results in high volume freshets, which typically peak from May to July. • There are approximately 220 waterbodies along the reactivated pipeline segment (TERA 2005). • Source test water for the Hinton to Hargreaves Segment is likely to be drawn from the Athabasca, Snaring, Miette and Fraser rivers, as well as Moose Lake.
Air Emissions	• Existing air quality along the Hinton to Hargreaves Segment is expected to be good. • The largest emission sources are vehicle traffic along Highway 16, Jasper Airport, and a power generation plant near Jasper Pump Station.
GHG Emissions	• The main source of GHG emissions are aerial patrols which are conducted for maintenance purposes.
Acoustic Environment	• The largest sources of sound in the ambient acoustical environment along this segment are forestry activities, small airport flight paths, train activities on railways and recreational and tourist activities. • The Hinton to Hargreaves Segment loosely parallels the Highway 16 transportation corridor. The ambient environment in close proximity to the highway will be elevated due to the presence of vehicle traffic. In general, if a heavily travelled roadway is within the Acoustic Environment LSA, then an elevated acoustic ambient environment may exist. AER *Directive 038: Noise Control Directive* (ERCB 2007) indicates that traffic affects ASLs at up to 500 m from the roadway, which is a consideration for assessing receptors within the Acoustic Environment LSA. • This segment only passes through the single moderately urbanized community of the Town of Jasper. The remainder of this pipeline segment is located in undeveloped, rural lands where natural sounds dominate existing background. Some human activity may occur, but would not appreciably affect sound levels. • The only applicable noise bylaw for this segment is the Municipality of Jasper Bylaw No. 108. The bylaw permits construction activities from 7:30 AM to 9 PM, 7 days a week with the exception of holidays in which case no construction activity is allowed.
Fish and Fish Habitat	• The Hinton to Hargreaves Segment lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. • There are 220 waterbodies along the reactivated pipeline segment, of which 49 are fish-bearing (TERAWestland 2005). • The section of the Athabasca River in Jasper National Park was designated as a Canadian Heritage River in 1989 (Canadian Heritage Rivers System 2011c). • Source test water for the Hinton to Hargreaves Segment is likely to be drawn from the Athabasca, Snaring, Miette and Fraser rivers, as well as Moose Lake. If hydrostatic test water is withdrawn from a nearby river or creek, an interaction with fish and fish habitat may occur. Fish species that may be found in the Athabasca and Fraser river basins are inferred based on fish species found in the Athabasca and Upper Fraser river watersheds (see Fisheries [Alberta] Technical Report and Fisheries [British Columbia] Technical Report of Volume 5C). • Provincially and federally-listed species of concern are inferred based on listed species found in the Athabasca and Upper Fraser river watersheds (see Table 4.3 of the Fisheries [Alberta] Technical Report of Volume 5C and Tables 4.4 and 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C). • White sturgeon is found in the Upper Fraser River Basin and is listed as Endangered under Schedule 1 of *SARA* (Environment Canada 2013o) and is Red-listed in BC (BC CDC 2013a). White sturgeon may reside in the upper Fraser River mainstem; their distribution is assumed to be low and they are not expected to inhabit smaller tributaries (Fisheries [British Columbia] Technical Report of Volume 5C). • Bull trout in the Athabasca and Fraser river basins near the reactivated pipeline segment are listed as a Species of Special Concern under COSEWIC (2013b). It is also designated Special Concern by the Alberta ESCC (AESRD 2012d) and is Blue-listed in BC (BC CDC 2013a). Bull trout is also an indicator species in Alberta. • Athabasca rainbow trout is considered to be At Risk in Alberta (ASRD 2011) and is in the process of being listed under the Alberta *Wildlife Act* and *Wildlife Regulation*. (AESRD 2012d). • Spiny sculpin is listed as May be At Risk in Alberta (ASRD 2011).

TABLE 5.13-1 Cont'd

Environmental Elements	Summary of Considerations
Wetland Loss or Alteration	• The Hinton to Hargreaves Segment is located within the Western Alberta Upland and Eastern Continental Ranges ecoregions. Within the Western Alberta Upland, wet areas are characterized by black spruce and tamarack, whereas within the Eastern Continental Ranges, wetlands are not common (Ecological Stratification Working Group 1995). • The Hinton to Hargreaves Segment is situated within three Wetland Regions of Canada. These regions are the South Rocky Mountain, Continental Mid-boreal and the South Interior Mountain regions (Government of Canada 1986). Common wetland types found within the South Rocky Mountain Wetland Region include flat bogs, horizontal fens and flood plain marshes with shallow basin marshes, while small basin fens and basin bogs occur in alpine areas. Treed bogs and fens, floating fens, shore swamps and marshes are often found within the Continental Mid-boreal Wetland Region. The wetlands found within the South Interior Mountain Wetland Region are characterised by flat bogs, basin bogs and shallow basin marshes with small basin fens and basin bogs found in alpine areas (Government of Canada 1986). • In Alberta, the Hinton to Hargreaves Segment is located within the Montane Natural Subregion of the Rocky Mountain Natural Region. Wetlands are rare in the Montane Natural Subregion, with fens and marshes occupying approximately 2% of the total Subregion area (Natural Regions Committee 2006b). • The Hinton to Hargreaves Segment is also located within two BGC zones of BC including the ICH and SBS zones (BC MFLNRO 2012, Meidinger and Pojar 1991). Wetlands comprise a small portion of the ICH Zone and are limited to valley bottoms where they are often associated with lakes and streams and include small swamps, and non-forested or sparsely forested wetlands (BC MOF 1996a). Within the SBS Zone, wetlands are commonly sedge marshes, shrub fens, swamps, treed fens and bogs (BC MOF 1998a, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species and cover for ungulates. • There are no Ramsar Wetlands of International Importance along the Hinton to Hargreaves Segment (Bureau of the Convention on Wetlands 2013). This segment of the existing pipeline corridor does not cross any Western Hemisphere Shorebird Reserves (WHSRN 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013n) or DUC Priority Areas (DUC 2013).
Vegetation	• The Hinton to Hargreaves Segment is situated within Environmentally Significant Areas 20 and 23 (Fiera Biological Consulting Ltd. 2009), Mount Robson Provincial Park as well as Jasper National Park. This segment does not encounter any legal OGMAs but encounters one non-legal OGMA (BC MFLNRO 2009a,b). • In Alberta, the Hinton to Hargreaves Segment is located within the Montane Natural Subregion of the Rocky Mountain Natural Region of Alberta. Vegetation communities in the Montane Natural Subregion are mainly comprised of closed forest communities dominated by lodgepole pine, Douglas-fir, trembling aspen and white spruce. Deciduous forests occur on fluvial fans, terraces and flood plains. Open grasslands occur on dry and exposed sites, and are dominated by various grasses including June grass, northern wheatgrass, western wheatgrass, Kentucky bluegrass and slender wheatgrass (Natural Regions Committee 2006a). • The Hinton to Hargreaves Segment is also located within two BGC zones of BC, including the ICH and SBS zones (BC MFLNRO 2012, Meidinger and Pojar 1991). The ICH BGC Zone has the highest diversity of tree species of any zone in BC. Western redcedar and western hemlock dominate mature climax forests, while lodgepole pine, trembling aspen and paper birch are common in all areas (Meidinger and Pojar 1991). The SBS BGC Zone dominates the central interior of BC. The climate in this zone is one of extremes; the winter is severe and snowy and the summers are relatively warm and moist. However, the winters are slightly shorter and the growing season is slightly longer than those of other boreal zones. The zone is characterized by upland coniferous forests of subalpine fir and hybrid white spruce. Major streams and rivers are bordered by alluvial forests that are dominated by black cottonwood and occasionally spruce (Meidinger and Pojar 1991). • A search of the ACIMS database and the BC CDC identified 101 occurrences of rare plant and lichen species within the Vegetation RSA in this segment (ACIMS 2012, BC CDC 2012). There are 35 vascular plant species, 43 moss species, 6 liverwort species, 14 lichen species and 3 vegetation communities of concern. • The only ground disturbance planned along this segment is where MLBVs will be installed or locations of potential integrity digs. The location of these MLBVs was not finalized when vegetation surveys were conducted in 2013 and, therefore, no vegetation surveys were conducted along this segment. Once the locations of the MLBVs are finalized, the need for vegetation surveys will be revisited. See Section 9.0 for information regarding supplemental studies. • This segment crosses Yellowhead County, Jasper National Park, Mount Robson Provincial Park and the RDFFG. Representatives from Yellowhead County were contacted, the Yellowhead County website was consulted, the NWIPC website was consulted for information about the RDFFG and the Non-Native Plants of Jasper Park Weed Identification Guide was reviewed regarding invasive non-native species of concern. For this segment, Noxious weed species of concern include: Canada thistle; common burdock; common tansy; dalmation toadflax; field scabious; leafy spurge; oxeye daisy; perennial sow thistle; scentless chamomile; tall buttercup; white cockle; yellow clematis; and yellow (common) toadflax (Pichette pers. comm., Parks Canada 2010). Prohibited Noxious weed species of concern include: orange, meadow and tall hawkweed; Himalayan balsam; spotted knapweed and big headed knapweed (Pichette pers. comm., Parks Canada 2010). Regionally-listed weeds include burdock and marsh plume thistle (NWIPC 2013). For a complete list of weed species of concern, see Section 4.4 of the Vegetation Technical Report of Volume 5C.

TABLE 5.13-1 Cont'd

Environmental Elements	Summary of Considerations
Wildlife and Wildlife Habitat	• The Hinton to Hargreaves Segment crosses grizzly bear secondary habitat from approximately KP 317.6 to KP 321.9 and grizzly bear core habitat from approximately KP 321.9 to KP 326.9 (AESRD 2013g). • The Hinton to Hargreaves Segment crosses the South Jasper caribou range from approximately KP 387.0 to KP 404.6 (AESRD 2013g). • The Hinton to Hargreaves Segment is located in an international Environmentally Significant Area (No. 23) from approximately KP 326.7 to KP 405.8 (ATPR 2009). • The Hinton to Hargreaves Segment is located in Jasper National Park from approximately KP 326.7 to KP 405.8 (ATPR 2012) and Mount Robson Provincial Park from approximately KP 405.8 to Hargreaves at approximately KP 468.0 (BC MFLNRO 2008b). • The proposed Project activities associated with pipeline reactivation are not expected to have a measurable effect on wildlife and wildlife habitat and, therefore, a detailed effects assessment for this element is not warranted for this component of the Project.
Species at Risk or Species of Special Status and Related Habitat	• Federally (*i.e.*, *SARA* and COSEWIC)-listed fish species that may be found in the basins crossed by the Hinton to Hargreaves Segment include: white sturgeon (listed under Schedule 1 of *SARA* [Environment Canada 2013o] and bull trout (considered a Species of Special Concern under COSEWIC [2013b]). • A search of the ACIMS database and the BC CDC identified two plant species listed as Threatened by COSEWIC and *SARA*: Haller's apple moss; and Porsild's Bryum moss (ACIMS 2012, BC CDC 2012, COSEWIC 2013b, Environment Canada 2013o). One species, whitebark pine, is listed as Endangered by COSEWIC and the Alberta *Wildlife Act* (AESRD 2012b, COSEWIC 2013b). • The Project activities associated with pipeline reactivation are not expected to have a measurable effect on wildlife and wildlife habitat and, therefore, a detailed effects assessment for this element is not warranted for this component of the Project.

5.13.2 Darfield to Black Pines Segment

The existing Darfield to Black Pines pipeline segment extends from 75-B/092-P-8 (RK 769.0) to 41-K/092-I-16 (RK 811.9). Surface disturbance along this segment is anticipated to be confined to the existing easement and will be limited to locations where automated MLBVs will be installed, where existing valves will be automated or where integrity digs are conducted. These locations have yet to be determined. Table 5.13-2 provides a summary of the biophysical elements and considerations for the reactivation of the Darfield to Black Pines Segment pursuant to Guide A.2.4 as well as Table A-2 of the NEB *Filing Manual*.

TABLE 5.13-2

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE DARFIELD TO BLACK PINES REACTIVATED SEGMENT

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Darfield to Black Pines Segment is located within the Interior Plateau Physiographic Region, which is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans and cones (Demarchi 2011, Holland 1976). • The Darfield to Black Pines Segment is predominantly underlain by igneous and metamporhic rock, in addition to sandstones and carbonates (BC ILMB 2013b, Monger and McMillan 1989). • Surficial materials along most of the Darfield to Black Pines Segment are characterized by till deposits along valley walls and upland surfaces, colluvial deposits along valley slopes and in fans and cones, and fluvial, glaciofluvial and glaciolacustrine deposits on plains and terraces (BGC Engineering Inc. 2013a). • There are no areas of permafrost along the Darfield to Black Pines Segment (refer to Section 5.1.1). • Debris flows and debris floods have the potential occur along the Darfield to Black Pines Segment. • The earthquake ground shaking hazard is low on lands crossed by the Darfield to Black Pines Segment. PGA is between 0.1 g and 0.2 g at a 1:2475 APE (BGC Engineering Inc. 2013c). • Topography along the segment ranges from gentle to moderate slopes along the valley bottom and lower valley slope areas and steeper hills where the segment deviates from the valley bottom.

TABLE 5.13-2 Cont'd

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment (cont'd)	• Elevations range from 390 m asl at the Darfield Pump Station to 700 m asl at the highest point west of Barrier, decreasing to 380 m asl at the Black Pines Pump Station. • The Darfield to Black Pines Segment is predominantly in the IDF BGC Zone, with the southernmost approximately 6 km of the segment located within the PP BGC Zone (Meidinger and Pojar 1991). A description of the climate for the IDF and PP BGC zones is provided in Sections 5.1.2 and 5.1.3, respectively. • Meteorological data from Environment Canada's Darfield Station, located approximately 1.8 km south of Darfield Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of the segment (NRCan 2010b,c).
Soil and Soil Productivity	• Surface disturbance to soils caused by reactivating the existing Darfield to Black Pines Segment is expected to be confined to the existing easement and will be limited to locations where valves will be installed or automated, or where integrity digs are conducted. • Soils in the Darfield to Black Pines Segment are dominated by Gray Luvisolic soils (Valentine *et al*. 1978). Luvisolic soils generally have light-coloured, eluvial horizons and have illuvial B horizons in which silicate clay has accumulated. These soils develop characteristically in well to imperfectly-drained sites, in sandy loam to clay, base-saturated parent materials under forest vegetation in subhumid to humid, mild to very cold climates (Agriculture and Agri-Food Canada 1998). • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• The Darfield to Black Pines Segment lies within the Lower North Thompson River Watershed. • Flow regimes along this segment are generally dominated by snowmelt. The North Thompson River, the major watercourse along the segment, is primarily influenced by climate patterns in the Columbia Mountains resulting in high spring freshet flows, while smaller watercourses have more variable flow regimes influenced by the transition from wetter climates to the north and dryer climates to the south. • Source test water for the Darfield to Black Pines Segment is likely to be drawn from the North Thompson River.
Air Emissions	• Existing air quality along the Darfield to Black Pines Segment is expected to be good. • The largest emission sources are vehicle traffic along Highway 5, forestry activities, and residential sources from the District of Barriere.
GHG Emissions	• The main source of GHG emissions are aerial patrols which are conducted for maintenance purposes.
Acoustic Environment	• The largest sources of sound within the ambient acoustical environment, along this segment of the proposed pipeline corridor, are forestry activities, highway traffic and rail traffic. • This segment generally parallels the Highway 5 transportation corridor. The ambient environment in close proximity to the highway will be elevated due to the presence of vehicle traffic. In general, if a heavily travelled roadway is within the Acoustic Environment LSA, then an elevated acoustic ambient environment may exist. BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) indicates that traffic affects ASLs at up to 500 m from the roadway, which is a consideration for assessing receptors within the Acoustic Environment LSA. • Part of the Town of Barriere falls within the Acoustic Environment LSA for this segment. The density of development in the town would result in ASLs being elevated by human activity. The ASL for homes in Barriere would be 38 dBA at night and 48 dBA during the day. • The Hamlets of Darfield, Chinook Cove, McClure, and the Hamlet of Black Pines are all found within this segment. Based on available mapping, these hamlets do not have populations large enough to modify the ASL, as per the BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). The remainder of the pipeline segment is located in undeveloped, rural lands where natural sounds dominate existing background. Some human activity may occur, but would not appreciably affect sound levels. As a result, except near Barriere, existing sound levels follow the rural ASL of 35 dBA at night and 45 dBA during the day as found in the BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009).
Fish and Fish Habitat	• The Darfield to Black Pines Segment lies within the Lower North Thompson River Watershed. • Source test water for the Darfield to Black Pines Segment is likely to be drawn from the North Thompson River. If hydrostatic test water is withdrawn from a nearby river or creek, an interaction with fish and fish habitat may occur. Of the five indicator species in BC, four (rainbow trout/steelhead, bull trout/Dolly Varden, coho salmon and Chinook salmon) are found in the Lower North Thompson River Watershed (Table 5.7-2 of Section 5.7) and may be found in watercourses crossed by the reactivated pipeline segment. • Bull trout and mountain sucker may be found in the Lower North Thompson Watershed and are both listed as a Species of Special Concern under COSEWIC (2013b) and are Blue-listed in BC (BC CDC 2013a) (see Table 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C). • Interior Fraser River coho salmon are Endangered under COSEWIC (2013b) and may be found in the Lower North Thompson River Watershed (Table 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C).

TABLE 5.13-2 Cont'd

Environmental Elements	Summary of Considerations
Wetland Loss or Alteration	• The Darfield to Black Pines Segment is located within the Columbia Highlands and the Thompson-Okanagan Plateau ecoregions. Wetlands are not very common within these ecoregions and many of those wetlands have been disturbed by urbanization and agriculture (Ecological Stratification Working Group 1995). • This segment is situated within the Intermountain Prairie Wetland Region of Canada. Common wetland types found within this wetland region include marshes bordering fresh to saline ephemeral or semi-permanent shallow waters (Government of Canada 1986). • The Darfield to Black Pines Segment is located within the IDF and PP BGC zones of BC (BC MFLNRO 2012, Meidinger and Pojar 1991). Common wetland types found within the IDF BGC Zone include fens, marshes dominated by cattails, sedges and bulrushes as well as shrubby swamps dominated by willows and birches, and occasionally saline meadow wetlands dominated by saltgrasses (BC MOF 1996b, Meidinger and Pojar 1991). Wetlands within the PP BGC Zone are not common, however, hydrophytic plants can be found in seepages and in riparian areas. Marshes associated with alkaline ponds may occur within restricted drainage depressions and basins (BC MOF 1998b, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species and cover for ungulates. • There are no Ramsar Wetlands of International Importance along the Darfield to Black Pines Segment (Bureau of the Convention on Wetlands 2013). This segment of the proposed pipeline corridor does not cross any Western Hemisphere Shorebird Reserves (WHSRN 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013n) or DUC Priority Areas (DUC 2013).
Vegetation	• This segment does not cross any provincial parks or recreation areas (BC MOE 2012b). This segment encounters 16 legal OGMAs and no non-legal OGMAs (BC MFLNRO 2009a,b). Of these OGMAs, five are crossed by the existing pipeline to be reactivated. • The Darfield to Black Pines Segment is located within the IDF and PP BGC zones of BC (BC MFLNRO 2012, Meidinger and Pojar 1991). The landscape of the IDF BGC Zone consists largely of open to closed, mature forests of Douglas-fir. Pure Douglas-fir climax stands are common. Mixed stands of Douglas-fir and lodgepole pine are often present in areas frequently affected by fire. Extensive grassland communities also occur in parts of the zone due to a combination of edaphic and topographic conditions and fire history. Non-forested wetlands are common in this zone and include marshes, sedge and shrub fens, shrub-carrs and saline meadows. Willow swamps often occur along small streams and drainages (Meidinger and Pojar 1991). The PP BGC Zone is the driest and has the warmest summer temperatures of all the forested zones in BC. The forests in this zone are dominated by very open PP stands with an understory consisting largely of bluebunch wheatgrass. Grasslands are commonly scattered throughout the zone. Fires have played an important role in the ecology of the zone. Alkaline ponds can occur in depressional areas (Meidinger and Pojar 1991). • The only ground disturbance planned along this segment is where MLBVs will be installed or locations of potential integrity digs. The location of these MLBVs was not finalized when vegetation surveys were conducted in 2013 and, therefore, no vegetation surveys were conducted along this segment. Once the locations of the MLBVs are finalized, the need for vegetation surveys will be revisited. See Section 9.0 for information regarding supplemental studies. • This segment crosses the TNRD, and representatives from this area were contacted regarding invasive non-native species of concern. Regionally-listed weeds include: blueweed; burdock; field scabious; hoary cress; orange hawkweed; oxeye daisy; perennial pepperweed; and sulphur cinquefoil (SIWMC 2013). Local invasive species include: blueweed; bull thistle; Canada thistle; common burdock; diffuse knapweed; dalmatian toadflax; hoary alyssum; hound's tongue; leafy spurge; orange hawkweed; spotted knapweed; sulphur cinquefoil; and scentless chamomile. Potentially invasive species of concern include: field scabious; marsh plume thistle; perennial pepperweed; rush skeletonweed; scotch thistle; and yellow starthistle (SIWMC 2013).
Wildlife and Wildlife Habitat	• The Darfield to Black Pines Segment does not cross any WHAs, UWR or designated caribou range (BC MOE 2005a,b, 2008). • The proposed Project activities associated with pipeline reactivation are not expected to have a measurable effect on wildlife and wildlife habitat and, therefore, a detailed effects assessment for this element is not warranted for this component of the Project.
Species at Risk or Species of Special Status and Related Habitat	• Bull trout and mountain sucker are both considered to be Species of Special Concern under COSEWIC (2013b). Interior Fraser River coho salmon are Endangered under COSEWIC (2013b). All three species may be found in the Lower North Thompson River Watershed. • A search of the BC CDC identified one occurrence of a rare plant or lichen species within the Vegetation RSA in this segment (BC CDC 2012). The species, Mexican mosquito fern, is listed as Threatened by COSEWIC and *SARA* (COSEWIC 2013b, Environment Canada 2013o). • The proposed Project activities associated with pipeline reactivation are not expected to have a measurable effect on wildlife and wildlife habitat and, therefore, a detailed effects assessment for this element is not warranted for this component of the Project.

6.0 ENVIRONMENTAL SETTING FOR FACILITIES

The following subsections present a summary of the environmental setting of the proposed facilities, including pump stations and associated power lines, tank terminals, Westridge Marine Terminal, pump stations to be reactivated and deactivated, and temporary facilities, pursuant to Guide A.2.4 of the National Energy Board (NEB) *Filing Manual* (NEB 2013). A summary of the proposed activities at these facilities is provided in Section 2.0, while a detailed description is provided in Volume 2. The following elements from the NEB *Filing Manual* are discussed in the tables below: physical and meteorological environment; soil and soil productivity; water quality and quantity; air emissions; greenhouse gas (GHG) emissions; acoustic environment; fish and fish habitat; wetland loss or alteration; vegetation; wildlife and wildlife habitat; and species at risk. In addition, the following elements are discussed in Table 6.2-1 for the Westridge Marine Terminal: marine sediment and water quality; marine fish and fish habitat; marine mammals; marine birds, and marine species at risk. The environmental setting was compiled based on the following sources:

- geotechnical, soil, groundwater, air, GHG, acoustic, fish, wetland, vegetation, wildlife and marine studies conducted for the Project (Volume 5C);
- existing published literature including topographic maps, aerial photography, scientific papers and reference books, as well as municipal, provincial and federal government maps, reports, interactive websites, guides, information letters, fact sheets, and databases; and
- consultation and engagement with Aboriginal communities (including Aboriginal Traditional Knowledge [ATK] and Traditional Ecological Knowledge [TEK]), landowners, regulatory authorities, stakeholders and the general public.

Methods of obtaining resource material included searching libraries, internet searches and documents from regulatory authorities. References used in the preparation of the environmental setting are cited in Section 6.5. Detailed methodology for the collection of information on existing conditions is provided in the applicable supporting studies in Volume 5C.

The settings for each element discuss the existing conditions for each indicator or set of indicators selected for the element. A summary of the indicators selected for the following elements is provided in Table 5-1: physical and meteorological environment; soil and soil productivity; water quality and quantity; air emissions; GHG emissions; acoustic environment; fish and fish habitat; wetland loss or alteration; vegetation; wildlife and wildlife habitat; and species at risk. A summary of the indicators selected for marine sediment and water quality, marine fish and fish habitat, marine mammals, marine birds and marine species at risk in the context of the Westridge Marine Terminal is provided in Table 6-1. The rationales for the selection of all indicators are provided in Section 7.0.

TABLE 6-1

SELECTED INDICATORS FOR MARINE ELEMENTS AT THE WESTRIDGE MARINE TERMINAL

Element	Indicators
Marine Sediment and Water Quality	• Marine sediment quality. • Marine water quality.
Marine Fish and Fish Habitat	• Marine riparian habitat. • Intertidal habitat. • Subtidal habitat. • Dungeness crab. • Inshore rockfish. • Pacific salmon (all five species).
Marine Mammals	• Pacific harbour seal.

TABLE 6-1 Cont'd

Element	Indicators
Marine Birds	• Bald eagle. • Great blue heron. • Pelagic cormorant. • Barrow's goldeneye. • Glaucous-winged gull. • Spotted sandpiper.
Marine Species at Risk	• Marine fish species at risk (*i.e.*, inshore rockfish). • Marine mammal species at risk (*i.e.*, Steller sea lion, harbour porpoise, northern fur seal and various whale species). • Marine bird species at risk (*i.e.*, pelagic cormorant and great blue heron).

The potential Project-related effects and mitigation are presented in Section 7.0. The spatial boundaries of elements discussed in the environmental setting are described in Section 5.0, with the exception of the marine spatial boundaries which are used in the context of the Westridge Marine Terminal and described in Section 6.2.

6.1 Pump Stations and Tank Terminals

Pump stations are positioned along the length of the existing Trans Mountain pipeline to maintain pressure, move the product along the line and monitor flow. To accommodate expansion activities, the Project will include construction and operation of new pump stations, and modification and/or replacement of existing pumps. In addition, 20 new storage tanks will be constructed at the Edmonton (5), Sumas (1) and Burnaby (14) terminals, respectively.

6.1.1 Edmonton Terminal

The existing Edmonton Terminal is located at SW 5-53-23 W4M at RK 0.0. The Edmonton Terminal is located on lands owned by Trans Mountain within Strathcona County and adjacent to the City of Edmonton. Adjacent lands are privately owned by various industrial companies. No disturbance of previously undisturbed lands is proposed at the Edmonton Terminal and all work will be conducted within the existing disturbed fenced area. Four 5,000 HP pump units will be added to the site, as well as one spare 5,000 HP pump unit. A new substation at the Edmonton Terminal will require a new power line. At the time of writing, the routing of the power line had yet to be determined by the Alberta Electric System Operator (AESO). Two new 34,980 m^3 (220,000 bbl) storage tanks, two new 63,600 m^3 (400,000 bbl) storage tanks and one new 11,920 m^3 (75,000 bbl) storage tank will be installed at the Edmonton Terminal. An existing 12,720 m^3 (80,000 bbl) storage tank will be dismantled and replaced by the new 11,920 m^3 (75,000 bbl) tank. Access to the Edmonton Terminal is via Baseline Road and 17th Street. Table 6.1-1 provides a summary of the environmental elements and considerations for the Edmonton Terminal pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Edmonton Terminal is shown on Figure 6.1-1.

TABLE 6.1-1

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE EDMONTON TERMINAL

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Edmonton Terminal is located within the Eastern Alberta Plains Physiographic Region, characterized by undulating plains, hummocky terrain, steep valley walls, active fluvial channels and glaciofluvial deltas (Natural Regions Committee 2006a, Pettapiece 1986). • The Edmonton Terminal is underlain by the Horseshoe Canyon Formation, which is characterized as interbedded non-marine sandstone, siltstone, shale, and numerous coal and bentonite beds (Hamblin 1998). • The surficial geology beneath the site is mapped as lacustrine fine sediment silt and clay in the northwest half; the southwest half is underlain by a stagnation moraine glacial till of uneven thickness (Shetsen 1990). • There are no areas of permafrost within the area of the Edmonton Terminal (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Edmonton Terminal. • The site is located in a zone of low seismic activity (Natural Resources Canada [NRCan] 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is less than 0.1 g (NRCan 2013a). No earthquakes have been recorded in the area (NRCan 2013b). • The topography in the area of Edmonton Terminal is relatively flat and the elevation is approximately 680 m above sea level. • Where activities are planned within Edmonton Terminal, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing station. • The Edmonton Terminal is located in an agricultural area considered to have low to moderate soil erosion risk (Alberta Agriculture and Rural Development [AARD] 2005a). Wind erosion risk, which assesses the risk of soil degradation by wind on bare, unprotected mineral soil, is considered low at the Edmonton Terminal (AARD 2005b). Water erosion risk, which assesses the risk of soil degradation by water on bare, unprotected mineral soil, is considered moderate to high in the vicinity of the site (AARD 2005c). • A description of the climate for the Central Parkland Natural Subregion is provided in Section 5.1.1. • The following meteorological data were obtained from an Environment Canada meteorological station (3012205) at Edmonton International Airport (Environment Canada 2013a). The data were taken approximately 29 km southwest of the Edmonton Terminal. – Average monthly rainfall for Edmonton Airport is 28.2 mm and the average monthly rainfall from June to August is 74.4 mm. In July of 1990, Edmonton Airport recorded its highest daily rainfall of 75.6 mm, which is below the monthly average of 95.6 mm for the month of July. – Average monthly snowfall for Edmonton Airport is 9.8 cm and the average monthly snowfall from November to February is 17.1 cm. In April of 1991, Edmonton Airport recorded its highest daily snowfall of 36.2 cm, well above the 14.4 cm average for the month of April. – Average daily temperature for Edmonton Airport is 2.6°C, with the warmest month in July, averaging 16.2°C and coolest month in January, averaging -12.1°C. In August of 2008, Edmonton Airport experienced its warmest day of 35.6°C and in January of 1972, its coolest day at -48.3°C. • One major tornado was recorded in the Edmonton area on July 31, 1987. It caused 27 deaths, 600 injuries, 1,700 evacuations and $300 million in damage (NRCan 2010b). Two major hailstorms were recorded in close proximity to the terminal: one in 1988 that caused $48 million in damage, and one in 1901 that produced 8 cm diameter hailstones (NRCan 2010c).
Soil and Soil Productivity	• Activities at the Edmonton Terminal will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • The Canada Land Inventory (CLI) (1967) has rated the soils in the vicinity of the Edmonton Terminal as having no limitations to crop production (Class 1). • Historical spills have occurred at the Edmonton Terminal. Trans Mountain currently monitors soil and groundwater at the site. Monitoring will continue and any remedial action will be conducted, as necessary, as part of ongoing operations. The Contamination Discovery Contingency Plan (Appendix B of the Facilities Environmental Protection Plan [EPP] of Volume 6C) will be implemented if needed during construction. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• The Edmonton Terminal is located within the Lower North Saskatchewan Watershed of the North Saskatchewan River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • Hydrostatic testing is planned for the piping and new tanks to be installed within the Edmonton Terminal. Water may be withdrawn and released from Trans Mountain's existing fire water pond at the Edmonton Terminal. Alternatively, test water may be diverted from a nearby river, subject to obtaining a water withdrawal permit, or purchased from municipalities depending on availability from natural sources. Following testing, water will be tested for contaminants before being treated and either discharged back into the fire water pond, trucked away, or released to a natural waterbody or the municipal sewer system. • Four domestic water wells are located more than 500 m but less than 1,500 m from the terminal. • Potential surface or groundwater quality contaminants associated with construction activities at the Edmonton Terminal include spillage of gasoline, diesel fuel, lubricating fluids and antifreeze.

TABLE 6.1-1 Cont'd

Environmental Elements	Summary of Considerations
Water Quality and Quantity (cont'd)	• The terrain at the Edmonton Terminal is reported to be generally level and groundwater flow likely follows topography towards the North Saskatchewan River which lies 1,100 m to the northwest of the site. • At the site, groundwater flow direction was noted by EBA Engineering Consultants Ltd. (2012) to the northwest with local southwest directed groundwater flow in the southwest corner of the site. • The surficial geology beneath the site is mapped as lacustrine fine sediment silt and clay in the northwest half; the southwest half is underlain by a stagnation moraine glacial till of uneven thickness (Shetsen 1990). • One water well record indicated a spring is located in or near the site at SW 5-53-23 W4M (Alberta Environment and Sustainable Resource Development [AESRD] 2013a). No water supply wells are mapped within the site boundary and no wells are located within the surrounding Water Quality and Quantity Local Study Area (LSA) (AESRD 2013a). • The Edmonton Terminal does not overlie any mapped aquifers. • Studies completed by EBA Engineering Consultants Ltd. between 2006 and 2012 indicate that at the south tank farm at Edmonton Terminal, hydrocarbon contamination is noted in soil (at tanks 5, 12, 14, 18 and D-3 area) and in the groundwater (at tanks 12, 14 and D-3 area) at low concentrations possibly because the wells were installed in highly plastic dense clay. Groundwater depth was noted as 0.2-3.6 m below ground level (bgl). Groundwater at the Edmonton Terminal site is currently monitored. • Four areas of localized recharge were noted (EBA Engineering Consultants Ltd. 2008). • In 2011, an increase in benzene concentration was noted at Tank 6 in monitoring wells 07MW07 and 07ME11; ethylbenzene concentration increased in 2011 and exceeded criteria. At Tank 12, benzene and ethylbenzene decreased since 2008; continued monitoring was recommended (EBA Engineering Consultants Ltd. 2012).
Air Emissions	• Continuous volatile organic compound (VOC), hydrogen sulfide (H_2S) and mercaptan emissions are primarily due to standing and working losses from existing product storage tanks at the Edmonton Terminal. • Fugitive emissions from leaks are expected to be a small contributor relative to emissions from existing tanks. • All existing pumps are electrically driven and are not direct sources of criteria air contaminants (CACs). • CAC and VOC emissions from regular testing of emergency diesel generators and fire water pumps are infrequent. • The largest sources of CAC emissions, except particulate matter (PM), in the Air Quality Regional Study Area (RSA) are vehicle traffic, non-road engines, heating, large industrial facilities such as oil refineries and electrical power generation. The largest sources of PM emissions in the area are industrial combustion, road dust and construction activities. The largest sources of VOC emissions are storage tank facilities, refineries, non-road motor vehicles and solvent evaporation. • Predicted VOC, H_2S and mercaptan concentrations in the Air Quality RSA due to existing operations at the Edmonton Terminal, as well as Enbridge Pipelines Inc. (South) Terminal, the Suncor refinery and other existing anthropogenic sources are presented in the Air Quality and Greenhouse Gas Technical Report of Volume 5C.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Edmonton Terminal are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of sulfur hexafluoride (SF_6) from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Products handled and stored in existing tanks contain trace levels of GHGs; small amounts might be released through fugitive or process emissions (*e.g.,* methane [CH_4] and formation of carbon dioxide [CO_2]). • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Edmonton Terminal. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA and RSA are refineries that surround the Edmonton Terminal location, major vehicle roadways, public recreation areas and urban residential sound. • No receptors were identified within the Acoustic Environment LSA. A worst case location along the 1.5 km Acoustic Environment LSA boundary will be used for assessment of compliance with Alberta Energy Regulator (AER) *Directive 038* (Alberta Energy Resources Conservation Board [ERCB] 2007). The nearest receptors are located approximately 1.9 km both northwest and southeast of the Edmonton Terminal fenceline. These receptors are within the Acoustic Environment RSA and will be evaluated in Sections 7.0 and 8.0 due to the potential for cumulative noise levels, as defined in AER *Directive 038,* to be affected. • The ambient sound level (ASL) over the Acoustic Environment RSA for the Edmonton terminal in the absence of regulated energy facilities ranges between 41-51 decibels (dBA) at night and 51-61 dBA during the day based on AER *Directive 038* (ERCB 2007). • Due to the density of development and high number of existing energy facilities in the area, a measurement program to define specific sound level contributions from the existing facilities was not practical as sound from each facility would cross-contaminate the next. The existing sound levels for the Edmonton Terminal have been determined by reviewing available existing ERCB and AER applications for noise impact assessments that define the conditions. • A noise model was generated based on existing conditions located at the Edmonton Terminal. Applicable buildings and shelters were modelled along with their appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Edmonton Terminal is expected to comply with the AER *Directive 038* permissible sound levels for the Acoustic Environment LSA and surrounding RSA receptors. • Detailed noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.

TABLE 6.1-1 Cont'd

Environmental Elements	Summary of Considerations
Fish and Fish Habitat	• The Edmonton Terminal is located within the Lower North Saskatchewan Watershed of the North Saskatchewan River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Hydrostatic testing is planned for the piping and new tanks to be installed within the Edmonton Terminal. Water may be withdrawn and released from Trans Mountain's existing fire water pond at the Edmonton Terminal. Test water may be diverted from a nearby river or creek, or purchased from municipalities depending on availability from natural sources. Refer to Sections 5.7.1 and 5.7.5.5 for a description of the fish and fish habitat that may be found in the vicinity of the Edmonton Terminal in the event that hydrostatic test water is withdrawn from a nearby river or creek. • Lake sturgeon, found in the North Saskatchewan River, have a general status of Undetermined in Alberta (Alberta Sustainable Resource Development [ASRD] 2010), but are considered Threatened under the Alberta *Wildlife Act* and *Wildlife Regulation* and Endangered under the Committee on the Status of Endangered Wildlife in Canada (COSEWIC 2013).
Wetland Loss or Alteration	• The Edmonton Terminal expansion is situated within the Aspen Parkland Ecoregion, a component of the Prairies Ecozone. Wetlands comprise approximately half of this ecoregion and consist of small lakes and ponds (Ecological Stratification Working Group 1995). • The Edmonton Terminal is also situated within the Transitional Mid-boreal Wetland Region (Government of Canada 1986). In this region, common wetlands include basin fens, bogs, swamps and marshes. Horizontal fens and floating fens also occur along drainageways and lakeshores (Government of Canada 1986). • The Edmonton Terminal is located in the Central Parkland Natural Subregion of the Parkland Natural Region. The typical wetland types include marshes, willow scrublands and seasonal ponds in the southern part of the subregion. Treed fens with shallow organic soils occur in the northwest (Natural Regions Committee 2006b). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species, and also provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Edmonton Terminal during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), Important Bird Areas (IBAs) (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (Western Hemisphere Shorebird Reserve Network [WHSRN] 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Edmonton Terminal. • The Edmonton Terminal is located within a Ducks Unlimited Canada (DUC) Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • The Edmonton Terminal is not located within the 1,000 m setback of provincially identified colonial nesting bird waterbodies or the 800 m setback of provincially identified trumpeter swan waterbodies (AESRD 2010-2012).
Vegetation	• The Edmonton Terminal is situated within the Aspen Parkland Ecoregion, a component of the Prairie Ecozone. In its native state, this ecoregion is characterized by trembling aspen, bur oak, shrubs and discontinuous fescue grasslands. Poorly-drained areas support communities dominated by willow and sedge species (Ecological Stratification Working Group 1995). • The Edmonton Terminal is located in the Central Parkland Natural Subregion of the Parkland Natural Region which is dominated by plains rough fescue in the southern and eastern areas of the subregion, while trembling aspen-dominated communities occur in moister habitats. (Natural Regions Committee 2006a). • A national Environmentally Significant Area (No. 690; North Saskatchewan River) is located approximately 0.2 km northwest of the Edmonton Terminal (Alberta Tourism, Parks and Recreation [ATPR] 2009). • Records of rare plant observations within 5 km of the Edmonton Terminal were acquired from the Alberta Conservation Information Management System (ACIMS 2013) database. No provincially-listed (ACIMS) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.

TABLE 6.1-1 Cont'd

Environmental Elements	Summary of Considerations
Wildlife and Wildlife Habitat	• The Edmonton Terminal is situated on disturbed industrial lands. • The Edmonton Terminal is not located within or adjacent to any Environmentally Significant Areas (ATPR 2009), provincial parks or protected areas (ATPR 2012), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013) or World Biosphere Reserves (United Nations Educational, Scientific and Cultural Organization [UNESCO] 2013). • The Edmonton Terminal is located in a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • The Edmonton Terminal is located in a Bald Eagle Sensitive Raptor Range and Sharp-tailed Grouse Range (AESRD 2013b). The Terminal is located in a disturbed industrial area is not considered suitable habitat for bald eagle or sharp-tailed grouse. • A national Environmentally Significant Area (No. 690; associated with the North Saskatchewan River) is located approximately 0.2 km northwest of the Edmonton Terminal (ATPR 2009). • A Key Wildlife and Biodiversity Zone (North Saskatchewan River) is located approximately 0.5 km northwest of the Edmonton Terminal (AESRD 2013b). • Strathcona Science Provincial Park is located approximately 1.1 km northwest of the Edmonton Terminal. • The Edmonton Terminal is located in Wildlife Management Unit (WMU) 248 (AESRD 2012b). • Project activities will be located within an existing previously disturbed industrial site which is not considered to be suitable wildlife habitat.
Species at Risk or Species of Special Status and Related Habitat	• Lake sturgeon, found in the North Saskatchewan River, are considered Threatened under the Alberta *Wildlife Act* (AESRD 2012a) and Endangered under COSEWIC (2013). • Records of rare plant observations within 5 km of the Edmonton Terminal were acquired from the ACIMS (2013) database. No federally-listed (*Species at Risk Act* [*SARA*] or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species were identified as having the potential to occur in the vicinity of the Edmonton Terminal (ASRD 2010, AESRD 2012a, COSEWIC 2013, Environment Canada 2012): – peregrine falcon (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: At Risk, Alberta *Wildlife Act* and *Wildlife Regulation:* Threatened); – little brown myotis (*SARA*: no status, COSEWIC: Endangered, provincial: Secure); and – tiger salamander (COSEWIC: Special Concern). • A search of the AESRD Fisheries and Wildlife Management Information System (FWMIS) database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species within 2 km of the Edmonton Terminal (AESRD 2013c): – peregrine falcon (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: At Risk, Alberta *Wildlife Act* and *Wildlife Regulation*: Threatened); and – tiger salamander (COSEWIC: Special Concern). • Given that the Edmonton Terminal is an existing facility and all work will occur within the existing fenced area on previously disturbed land, the Edmonton Terminal is not considered suitable habitat for wildlife or plant species at risk.

6.1.2 Gainford Pump Station

The existing Gainford Pump Station is located at NE 13-53-6 W5M at RK 117.5. The Gainford Pump Station is located on lands owned by Trans Mountain in Parkland County. Current land use at this facility site is industrial and the surrounding land is forested. Some treed lands will be disturbed within the existing boundary of the Gainford Pump Station. Three 5,000 HP pump units will be installed at the site. Access to the Gainford Pump Station is via Highway 16. Table 6.1-2 provides a summary of the environmental elements and considerations for the Gainford Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Gainford Pump Station is shown on Figure 6.1-2.

TABLE 6.1-2

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE GAINFORD PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Gainford Pump Station is located within the Eastern Alberta Plains Physiographic Region, characterized by undulating plains, hummocky terrain, steep valley walls, active fluvial channels and glaciofluvial deltas (Natural Regions Committee 2006a, Pettapiece 1986). • The Gainford Pump Station is underlain by the Scollard Formation, which is characterized by two units: the lower “barren” member and the upper coal-bearing member. The lower member is characterized as thick greenish-grey shales and thin sandstones. The upper member is characterized as dark grey, bentonitic mudstones with coals (Hamblin 2010). • The surficial geology beneath the site is mapped stagnation moraine glacial till of uneven thickness (Shetsen 1990). • There are no areas of permafrost within the area of the Gainford Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Gainford Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is 0.04 g (NRCan 2013a). No earthquakes have been record in the area (NRCan 2013b). • The topography in the area of Gainford Pump Station is relatively flat but with a slight grade change from north to south and the elevation is approximately 760 m above sea level. • Where activities are planned within Gainford Pump Station, construction of the new infrastructure will be conducted within the boundaries of the existing station, however, some of the required land is forested. NRCan considers unprotected soils in the vicinity of Gainford Pump Station to have low wind erosion risk with low climatic sensitivity (NRCan 2010d). • The Gainford Pump Station is located in an agricultural area considered to have low soil erosion risk (AARD 2005a). Wind erosion risk, which assesses the risk of soil degradation by wind on bare, unprotected mineral soil, is considered negligible to low at the pump station (AARD 2005b). Water erosion risk, which assesses the risk of soil degradation by water on bare, unprotected mineral soil, is considered high to severe in the vicinity of the site (AARD 2005c). • A description of the climate for the Dry Mixedwood Natural Subregion is provided in Section 5.1.1. • Meteorological data from Environment Canada’s Entwistle Station, located approximately 15 km west of the Gainford Pump Station, are provided in Section 5.1.1. • No major tornadoes or hailstorms have been recorded in the vicinity of Gainford Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Project activities will cause some disturbance outside of the fenceline of the Gainford Pump Station but within the existing property boundary. The current Gainford Pump Station has been previously disturbed and contains pumps, buildings and other equipment. • The Gainford Pump Station is located in the Dry Mixedwood Natural Subregion. Typical soils in the Dry Mixedwood Natural Subregion are Orthic Gray Luvisols under moderately well-drained aspen forests (Natural Regions Committee 2006a). • The CLI (1971) has rated the soils in the vicinity of the Gainford Pump Station as having moderately severe limitations to crop production (Class 3) due to undesirable soil structure and/or low permeability. • No spills have been recorded at the Gainford Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. • Clubroot is a soil-borne disease that affects canola and other crops in the mustard family. It is considered a pest under the *Agricultural Pests Act*. Occurrences of clubroot have been identified in Parkland County (Leskiw pers. comm.), however, no occurrences have been identified within the Gainford Pump Station.
Water Quality and Quantity	• The Gainford Pump Station is located within the Upper North Saskatchewan River Watershed of the North Saskatchewan River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain is reported to be generally level at the Gainford Pump Station. • Groundwater flow likely follows topography towards Wabamun Lake which lies 1,800 m to the southeast of the site. • The surficial geology beneath the site is mapped stagnation moraine glacial till of uneven thickness (Shetsen 1990). • No water supply wells are mapped within the site boundary (AESRD 2013a). • Four water well records are indicated within NE 13-53-6 W5M designated as domestic use (AESRD 2013a). Additional water well records are noted to the east in 13-18-53-5 W5M with depths of 36 m and water levels ranging from 7.9-8.2 m bgl. These wells are all deeper than 30 m with water levels in the range of 0.9-23 m bgl (AESRD 2013a). • The Gainford Pump Station does not overlie any mapped aquifers.
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Gainford Pump Station are estimated to be 2.5 tonnes per year. • Air quality in the area surrounding the Gainford Pump Station is primarily a function of anthropogenic source emissions arising from power generation plants in the area and vehicle traffic on nearby roads.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Gainford Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Gainford Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.

TABLE 6.1-2 Cont'd

Environmental Elements	Summary of Considerations
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 16 and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 140 m to the east of the fenceline of the Gainford Pump Station. • ASL in the absence of regulated energy facilities is approximately 40 dBA at night and 50 dBA during the day based on AER *Directive 038* (ERCB 2007). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Gainford Pump Station complies with the AER *Directive 038* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Gainford Pump Station is located within the Upper North Saskatchewan River Watershed of the North Saskatchewan River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Gainford Pump Station is situated within the Aspen Parkland Ecoregion, a component of the Prairies Ecozone. Wetlands comprise approximately half of this ecoregion and consist of small lakes and ponds (Ecological Stratification Working Group 1995). • The Gainford Pump Station is also located within the Transitional Mid-boreal Wetland Region, a component of the Boreal Wetland Region of Canada. In this region, common wetlands include basin fens, bogs, swamps and marshes. Horizontal fens and floating fens also occur along drainageways and lakeshores (Government of Canada 1986). • The Gainford Pump Station is located in the Dry Mixedwood Natural Subregion of the Boreal Forest Natural Region of Alberta. Treed, shrubby or sedge-dominated fens are common to this area (Natural Regions Committee 2006b). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species, and also provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Gainford Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Gainford Pump Station. • The Gainford Pump Station is located within a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • The Gainford Pump Station is not located within the 1,000 m setback of provincially identified colonial nesting bird waterbodies or the 800 m setback of provincially identified trumpeter swan waterbodies (AESRD 2010-2012).
Vegetation	• The Gainford Pump Station is situated within the Aspen Parkland Ecoregion, a component of the Prairie Ecozone. In its native state, this ecoregion is characterized by trembling aspen, bur oak, shrubs and discontinuous fescue grasslands. Poorly-drained areas support communities dominated by willow and sedge species (Ecological Stratification Working Group 1995). • The Gainford Pump Station is located in the Dry Mixedwood Natural Subregion of the Boreal Forest Natural Region of Alberta. Aspen forests with understories dominated by shrubs are typical of the uplands. Treed, shrubby or sedge-dominated fens are common in wet areas. Jack pine typically dominates dry, well-drained areas (Natural Regions Committee 2006a). • Two provincial Environmentally Significant Areas (No. 441 and No. 442) with important rare plant habitat are located approximately 1 km northwest and 0.9 km southeast, respectively, from the Gainford Pump Station (ATPR 2009). • Records of rare plant observations within 5 km of the Gainford Pump Station were acquired from the ACIMS (2013) database. One provincially-listed (ACIMS) species record was found within the boundaries of the Vegetation LSA, marsh muhly, but not within the boundaries of the facility site. • A ground-based vegetation survey was conducted on July 18, 2013. Dominant communities observed during the 2013 vegetation survey consist of a deciduous forest dominated by trembling aspen, and a seeded area dominated by agronomic grasses and herbs. No rare plants or rare ecological communities were observed at the Gainford Pump Station during the 2013 vegetation survey. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications. • During the 2013 vegetation survey, five Noxious weed species were observed: Canada thistle; common tansy; ox-eye daisy; perennial sow-thistle; and tall buttercup. No Prohibited Noxious weeds were observed.

TABLE 6.1-2 Cont'd

Environmental Elements	Summary of Considerations
Wildlife and Wildlife Habitat	• The Gainford Pump Station is located adjacent to an existing pump station on industrial and forested lands. Dominant communities consist of a deciduous forest dominated by trembling aspen and a seeded area dominated by agronomic grasses and herbs. • The Gainford Pump Station is not located within or adjacent to any Environmentally Significant Areas (ATPR 2009), provincial parks or protected areas (ATPR 2012), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), or provincially identified wildlife areas (AESRD 2013b). • The Gainford Pump Station is located in a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • Two provincial Environmentally Significant Areas (No. 441 and No. 442) with important wildlife habitat are located approximately 1 km northwest and 0.9 km southeast, respectively, from the Gainford Pump Station (ATPR 2009). • The Gainford Pump Station is located in WMU 336 (AESRD 2012b). • A supplemental wildlife survey will be conducted (see Section 9.0).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Gainford Pump Station were acquired from the ACIMS (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species was identified as having the potential to occur in the vicinity of the Gainford Pump Station (ASRD 2010, COSEWIC 2013, Environment Canada 2012): − little brown myotis (COSEWIC: Endangered, provincial: Secure). • A search of the AESRD FWMIS database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species within 2 km of the Gainford Pump Station (AESRD 2013c). • Given that new clearing of forested lands will be required for the Gainford Pump Station, the Gainford Pump Station has the potential to be suitable habitat for wildlife and plant species at risk. • A supplemental survey for wildlife species at risk will be conducted (see Section 9.0).

6.1.3 Wolf Pump Station

The existing Wolf Pump Station is located at NW 19-53-14 W5M at RK 206.2. The Wolf Pump Station is located on lands owned by Trans Mountain in Yellowhead County. Current land use at and around this facility site is industrial and forested. No disturbance of previously undisturbed lands is proposed at the Wolf Pump Station (*i.e.,* no native vegetation would be directly disturbed within the site boundaries). Two 5,000 HP pump units will be added at the site. The existing pump building will be deactivated. Access to the Wolf Pump Station is via Highway 16. Table 6.1-3 provides a summary of the environmental elements and considerations for the Wolf Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Wolf Pump Station is shown on Figure 6.1-3.

TABLE 6.1-3

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE WOLF PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Wolf Pump Station is located within the Western Alberta Plains Physiographic Region, characterized by undulating plains, less abundant hummocky terrain and incised river valleys (Natural Regions Committee 2006a, Pettapiece 1986). • The Wolf Pump Station is underlain by the Paskapoo Formation, which is characterized by a thick sequence of Paleocene sand and siltstones, consisting of buff medium-grained sandstone overlain by interbedded light grey soft sandy siltstone and mudstones (Dawson *et al*. 1994, Hamblin 2004). • The surficial geology beneath the site is mapped as Edson Till consisting of moraine deposits of stones in a silty clay matrix (Roed 1970). • There are no areas of permafrost within the area of the Wolf Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Wolf Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is less than 0.1 g (NRCan 2013a). No earthquakes have been recorded in the area (NRCan 2013b). • The topography in the area of Wolf Pump Station is generally flat with a slight grade change from south to north. Elevation is approximately 880 m above sea level. • Where activities are planned within Wolf Pump Station, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing station. NRCan considers unprotected soils in the vicinity of Wolf Pump Station to have low wind erosion risk with low climatic sensitivity (NRCan 2010d). • The Wolf Pump Station is located in an agricultural area considered to have low soil erosion risk (AARD 2005a). Wind erosion risk, which assesses the risk of soil degradation by wind on bare, unprotected mineral soil, is considered low at the pump station (AARD 2005b). Water erosion risk, which assesses the risk of soil degradation by water on bare, unprotected mineral soil, is considered severe in the vicinity of the site (AARD 2005c). • A description of the climate for the Lower Foothills Natural Subregion is provided in Section 5.1.1. • Meteorological data from Environment Canada's Edson Station, located approximately 30 km west of Wolf Pump Station, are provided in Section 5.1.1. • No major tornadoes or hailstorms have been recorded in the vicinity of Wolf Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Wolf Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • A soil survey at the Wolf Pump Station was conducted in 2005 for the TMX Anchor Loop Project. Imperfectly-drained gleyed gray Luvisols developed on stone-free to slightly stony, silty clay to clay textured glaciolacustrine material (Lendrum soils) occur throughout the site. There is little to no topsoil present at the site (Mentiga 2005a). • The CLI (1973a) has rated soils at the Wolf Pump Station as having severe (Class 4) limitations to agriculture due to undesirable soil structure and excess moisture. • No contamination is anticipated at the Wolf Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented.
Water Quality and Quantity	• The Wolf Pump Station is located within the Lower McLeod River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain is reported as sloping slightly from south to north and groundwater flow likely follows topography towards January Creek located 160 m to the northwest. • The surficial geology beneath the site is mapped as Edson Till consisting of moraine deposits stones in a silty clay matrix (Roed 1970). • Water well records indicate three flowing shot-holes within the Water Quality and Quantity LSA; two nearby water wells have water levels of approximately 4-6 m bgl. • No water supply wells are mapped within the site boundary (AESRD 2013a). • The Wolf Pump Station does not overlie any mapped aquifers.
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Wolf Pump Station are estimated to be 1.7 tonnes per year. • Air quality in the area surrounding the Wolf Pump Station is expected to be primarily influenced by vehicle traffic emissions along Highway 16, nearby oil and gas facilities, and agricultural activity in the area.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Wolf Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Wolf Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Although two new pump units are being added, existing pump units of equivalent sound emission will be deactivated. No increase in sound emissions is expected from the Project at the Wolf Pump Station during operations and, therefore, detailed information on sound emissions is not warranted as per Table A-1 of the NEB *Filing Manual*.

TABLE 6.1-3 Cont'd

Environmental Elements	Summary of Considerations
Fish and Fish Habitat	• The Wolf Pump Station is located within the Lower McLeod River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Wolf Pump Station is situated within the boundaries of the Boreal Transition Ecoregion of the Boreal Plains Ecozone. Small lakes, ponds and marshes occupy shallow depressions within this ecoregion (Ecological Stratification Working Group 1995). • The Wolf Pump Station is also located in the Continental Mid-boreal Wetland Region. Wetlands characteristic of this region include flat and basin bogs often associated with horizontal and ribbed fens. Plateau bogs occur occasionally in large fens. Marshes can be found along gently sloping lakeshores (Government of Canada 1986). • The Wolf Pump Station is located within the Lower Foothills Natural Subregion of the Foothills Natural Region. Wetlands are predominantly treed fens, bogs and open fens (Natural Regions Committee 2006b). • No wetlands were identified within or adjacent to the Wolf Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Wolf Pump Station. • The Wolf Pump Station is located within a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • The Wolf Pump Station is not located within the 1,000 m setback of provincially identified colonial nesting bird waterbodies or the 800 m setback of provincially identified trumpeter swan waterbodies (AESRD 2010-2012).
Vegetation	• The Wolf Pump Station is located within the boundaries of the Boreal Transition Ecoregion of the Boreal Plains Ecozone. In its native state, this ecoregion is characterized by trembling aspen, balsam poplar, white spruce, balsam fir and a thick understory of tall shrubs and herbs. Poorly-drained areas support communities of willow species and sedges, with black spruce and tamarack occurring occasionally (Ecological Stratification Working Group 1995). • The Wolf Pump Station is located in the Lower Foothills Natural Subregion of the Foothills Natural Region. The Lower Foothills Natural Subregion is dominated by mixed stands of trembling aspen, lodgepole pine, white spruce and balsam poplar. Understory communities are dominated by shrubs and herbs (Natural Regions Committee 2006a). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA around the Wolf Pump Station. • Records of rare plant observations within 5 km of the Wolf Pump Station were acquired from the ACIMS (2013) database. No provincially-listed (ACIMS) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Wolf Pump Station is located on industrial and forested lands. • The Wolf Pump Station is not located within or adjacent to any Environmentally Significant Areas (ATPR 2009), provincial parks or protected areas (ATPR 2012), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), or provincially identified wildlife areas (AESRD 2013b). • The Wolf Pump Station is located in a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • The Wolf Pump Station is located in WMU 346 (AESRD 2012b). • Project activities will be located within an existing previously disturbed industrial site which is not considered to be suitable wildlife habitat.
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Wolf Pump Station were acquired from the ACIMS (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species was identified as having the potential to occur in the vicinity of the Wolf Pump Station (ASRD 2010, COSEWIC 2013, Environment Canada 2012): – little brown myotis (COSEWIC: Endangered, provincial: Secure). • A search of the AESRD FWMIS database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species within 2 km of the Wolf Pump Station (AESRD 2013c). • Given that the Wolf Pump Station is an existing facility and all work will occur on previously disturbed cleared land, the Wolf Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.4 Edson Pump Station

The existing Edson Pump Station is located at SW 18-53-18 W5M at RK 247.1. The Edson Pump Station is located on lands owned by Trans Mountain in Yellowhead County. Current land use at and around this facility site is industrial. All work will be conducted within the existing disturbed fenced area at the Edson Pump Station. No native vegetation would be directly disturbed within the site boundaries. Three 5,000 HP pump units will be added at the site. A new power line will be required to service Project upgrades to the existing substation at the Edson Pump. At the time of writing, the routing of the power line had yet to be determined by the AESO. Access to the Edson Pump Station is via Highway 16. Table 6.1-4 provides a summary of the environmental elements and considerations for the Edson Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Edson Pump Station is shown on Figure 6.1-4.

TABLE 6.1-4

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE EDSON PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Edson Pump Station is located within the Western Alberta Plains Physiographic Region, characterized by undulating plains, less abundant hummocky terrain and incised river valleys (Natural Regions Committee 2006a, Pettapiece 1986). • The Edson Pump Station is underlain by the Paskapoo Formation, which is characterized by a thick sequence of Paleocene sand and siltstones, consisting of buff medium-grained sandstone overlain by interbedded light grey soft sandy siltstone and mudstones (Dawson *et al*. 1994, Hamblin 2004). • The surficial geology beneath the site is mapped as Marlboro Till consisting of moraine deposits stones in a silty clay matrix and the underlying materials in the southwest half of the site consist of glaciolacustrine lake sediments (Roed 1970). • There are no areas of permafrost within the area of the Edson Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Edson Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is less than 0.1 g (NRCan 2013a). Several minor earthquakes (magnitude 3) have been recorded in the vicinity of the pump station (NRCan 2013b). • The topography in the area of Edson Pump Station is relatively flat to gently sloping and the elevation is approximately 940 m above sea level. • Where activities are planned within Edson Pump Station, soils have been disturbed for industrial use. Construction of the new infrastructure will be conducted within the boundaries of the existing station. NRCan considers unprotected soils in the vicinity of Edson Pump Station to be low or negligible (NRCan 2010d). • The Edson Pump Station is located in an agricultural area considered to have low soil erosion risk (AARD 2005a). Wind erosion risk, which assesses the risk of soil degradation by wind on bare, unprotected mineral soil, is considered negligible at the pump station (AARD 2005b). Water erosion risk, which assesses the risk of soil degradation by water on bare, unprotected mineral soil, is considered severe in the vicinity of the site (AARD 2005c). • A description of the climate for the Lower Foothills Natural Subregion is provided in Section 5.1.1. • Meteorological data from Environment Canada's Edson Station, located approximately 10 km east of the Edson Pump Station, are provided in Section 5.1.1. • No major tornadoes or hailstorms have been recorded in the vicinity of Edson Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Edson Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • The CLI (1973b) has rated the soils in the vicinity of the Edson Pump Station as having moisture and adverse climate limitations (Class 6) and are only capable of producing perennial forage crops. • No contamination is anticipated at the Edson Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented.
Water Quality and Quantity	• The Edson Pump Station is located within the Upper McLeod River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain is reported as generally level with a gentle slope from north to south. Groundwater flow likely follows topography towards Sundance Creek approximately 150 m to the south. • The surficial geology beneath the site is mapped as Marlboro Till consisting of moraine deposits stones in a silty clay matrix and the underlying materials in the southwest half of the site consist of glaciolacustrine lake sediments (Roed 1970). • Water wells, for which information is available, are completed in bedrock. • No water supply wells are mapped within the site boundary (AESRD 2013a). • The Edson Pump Station does not overlie any mapped aquifers.
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Edson Pump Station are estimated to be 5.6 tonnes per year. • Air quality in the area surrounding the Edson Pump Station is influenced by residential sources, rail station activity emissions, oil and gas and forestry industrial sources, and potential long-range transport of PM emissions from forest fires in the region.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Edson Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Edson Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.

TABLE 6.1-4 Cont'd

Environmental Elements	Summary of Considerations
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 16, surrounding arterial roadways and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 360 m to the west of the fenceline of the Edson Pump Station. • ASL in the absence of regulated energy facilities ranges between 35-40 dBA at night and 45-50 dBA during the day based on AER *Directive 038* (ERCB 2007). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Edson Pump Station complies with the AER *Directive 038* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Edson Pump Station is located within the Upper McLeod River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Edson Pump Station is situated within the boundaries of the Boreal Transition Ecoregion of the Boreal Plains Ecozone. Small lakes, ponds and marshes occupy shallow depressions within this ecoregion (Ecological Stratification Working Group 1995). • The Edson Pump Station is also located within the Continental Mid-boreal Wetland Region. Wetlands characteristic of this region include flat and basin bogs often associated with horizontal and ribbed fens. Plateau bogs occur occasionally in large fens. Marshes can be found along gently sloping lakeshores (Government of Canada 1986). • The Edson Pump Station and associated power lines are located in the Lower Foothills Natural Subregion of the Foothills Natural Region. Wetlands characteristic of this natural subregion include treed fens with some bogs and open fens (Natural Regions Committee 2006b). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Edson Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Edson Pump Station. • The Edson Pump Station is located within a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • The Edson Pump Station is not located within the 1,000 m setback of provincially identified colonial nesting bird waterbodies or the 800 m setback of provincially identified trumpeter swan waterbodies (AESRD 2010-2012).
Vegetation	• The Edson Pump Station is located within the boundaries of the Boreal Transition Ecoregion of the Boreal Plains Ecozone. In its native state, this ecoregion is characterized by trembling aspen, balsam poplar, white spruce, balsam fir and a thick understory of tall shrubs and herbs. Poorly-drained areas support communities of willow species and sedges, with black spruce and tamarack occurring occasionally (Ecological Stratification Working Group 1995). • The Edson Pump Station is located in the Lower Foothills Natural Subregion of the Foothills Natural Region. The Lower Foothills Natural Subregion is dominated by mixed stands of trembling aspen, lodgepole pine, white spruce and balsam poplar. Understory communities are dominated by shrubs and herbs (Natural Regions Committee 2006a). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Edson Pump Station. • Records of rare plant observations within 5 km of the Edson Pump Station were acquired from the ACIMS (2013) database. No provincially-listed (ACIMS) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Edson Pump Station is located on industrial lands. • The Edson Pump Station is not located within or adjacent to any Environmentally Significant Areas (ATPR 2009), provincial parks or protected areas (ATPR 2012), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), or provincially identified wildlife areas (AESRD 2013b). • The Edson Pump Station is located in a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • Hornbeck Creek Provincial Recreation Area is approximately 1.9 km southwest of the Edson Pump Station (APTR 2012). • A provincial Environmentally Significant Area (No. 72) with important wildlife habitat is located approximately 1.9 km southwest of the Edson Pump Station (ATPR 2009). • The Edson Pump Station is located in WMU 346 (AESRD 2012b).

TABLE 6.1-4 Cont'd

Environmental Elements	Summary of Considerations
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Edson Pump Station were acquired from the ACIMS (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species was identified as having the potential to occur in the vicinity of the Edson Pump Station (ASRD 2010, COSEWIC 2013, Environment Canada 2012): – little brown myotis (COSEWIC: Endangered, provincial: Secure). • A search of the AESRD FWMIS database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species within 2 km of the Edson Pump Station (AESRD 2013c). • Given that the Edson Pump Station is an existing facility and all work will occur within the existing fenced area on previously disturbed land, the Edson Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.5 Hinton Pump Station

The existing Hinton Pump Station is located at NW 33-49-26 W5M at RK 339.4. The Hinton Pump Station is located on lands owned by Trans Mountain in Yellowhead County. Expansion of the Hinton Pump Station will require acquisition of approximately 0.32 ha of new Crown land to the west of and adjacent to existing Trans Mountain lands. Three 5,000 HP pump units will be added at the site. Access to the Hinton Pump Station is via Highway 16. Table 6.1-5 provides a summary of the environmental elements and considerations for the Hinton Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Hinton Pump Station is shown on Figure 6.1-5.

TABLE 6.1-5

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE HINTON PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Hinton Pump Station is located within the Southern Alberta Uplands Physiographic Region, which is characterized by hummocky terrain, rolling uplands, gently undulating terraces and incised river valleys (Natural Regions Committee 2006a, Pettapiece 1986). • The Hinton Pump Station is underlain by the Alberta Group, which is composed of dominantly dark grey, silty mudstones and a prominent middle sandstone sequence (Glass 1990). • The surficial geology beneath the site is mapped as moraine silty sand till (unsorted clay to bolder size material) (Roed 1970). • There are no areas of permafrost within the area of the Hinton Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Hinton Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). Several minor earthquakes (magnitude 3) have been recorded in the vicinity of the pump station (NRCan 2013b). • The topography in the area of the Hinton Pump Station is gently sloping and the elevation is approximately 1,110 m above sea level. • Where activities are planned within the Hinton Pump Station, soils have been disturbed for industrial use, however, construction of the new infrastructure will require extending the existing fenceline to the west by approximately 35 m into a grassland/forested area, increasing the station operating area by approximately 0.3 ha. NRCan considers unprotected soils in the vicinity of the Hinton Pump Station to be low or negligible (NRCan 2010d). • A description of the climate for the Montane Natural Subregion is provided in Section 5.1.1. • The following meteorological data were obtained from an Environment Canada meteorological station (3053520) in Jasper, Alberta (Environment Canada 2013a). The data were taken approximately 50 km south-southwest of Hinton Pump Station. – Average monthly rainfall for Jasper is 25.4 mm and the average monthly rainfall from June to August is 59.6 mm. In August of 1969, Jasper recorded its highest daily rainfall of 107.7 mm, which is above the monthly average of 64.6 mm for the month of August. – Average monthly snowfall for Jasper is 10 cm and the average monthly snowfall from November to February is 21 cm. In February of 1948, Jasper recorded its highest daily snowfall of 51.6 cm, well above the 14.7 cm average for the month of February. – Average daily temperature for Jasper is 3.6°C, with the warmest month in July, averaging 15.2°C and coolest month in December, averaging -9.1°C. In July of 1941, Jasper experienced its warmest day of 36.7°C and in January of 1935, its coolest day at -46.7°C. • No major tornadoes or hailstorms have been recorded in the vicinity of Hinton Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Project activities will cause some disturbance to soil outside of the existing fenceline of the Hinton Pump Station to the west. The current Hinton Pump Station has been previously disturbed and contains pumps, buildings and other equipment. • A soil survey at the Hinton Pump Station was conducted in 2005 for the Trans Mountain Pump Station Expansion Project. Well-drained, Calcareous Brunisolic Gray Luvisols developed on strongly calcareous, very stony Cordilleran till (Dalehurst soils) occur in the central and eastern portions while well-drained Calcareous Orthic Brunisols developed on stone-free eolian sandy loams and loams overlying very stony till (Kia Nea soils) occur in the western portion. Soils at the site are susceptible to wind erosion and to compaction and rutting when wet (Mentiga 2005b). • The forest productivity rating of soils at the site indicates an expected mean annual productivity of about 2.5 m^3/ha (Dumanski *et al.* 1972). Soil toxicity limits forest productivity due to excessive concentrations of alkalinity or lime, which impedes tree growth. • The CLI (1973b) has rated soils at the site as having such severe (Class 6) limitations due to adverse topography that they are only capable of producing perennial forage crops. • No contamination is anticipated at the Hinton Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented.
Water Quality and Quantity	• The Hinton Pump Station is located within Athabasca River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain is reported sloping from west to east. Groundwater flow likely follows topography towards Maskuta Creek located approximately 280 m to the east-southeast. • The surficial geology beneath the site is mapped as moraine silty sand till (unsorted clay to bolder size material) (Roed 1970). • No water well records are noted at the facility site or within the Water Quality and Quantity LSA. • No water supply wells are mapped within the site boundary (AESRD 2013a). • The Hinton Pump Station does not overlie any mapped aquifers.
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Hinton Pump Station are estimated to be 1.9 tonnes per year. • Air quality in the area surrounding the Hinton Pump Station is primarily influenced by anthropogenic sources including industrial sources in the pulp and paper, oil and gas, and forestry industries.

TABLE 6.1-5 Cont'd

Environmental Elements	Summary of Considerations
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Hinton Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Hinton Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 16 and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 820 m to the southwest of the fenceline of the Hinton Pump Station. • ASL in the absence of regulated energy facilities ranges between 35-40 dBA at night and 45-50 dBA during the day based on AER *Directive 038* (ERCB 2007). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Hinton Pump Station complies with the AER *Directive 038* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Hinton Pump Station is located within the Athabasca River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Hinton Pump Station is situated within the boundaries of the Western Alberta Upland Ecoregion of the Boreal Plains Ecozone. Marshes and bogs are common within this ecoregion (Ecological Stratification Working Group 1995). • The Hinton Pump Station is also located within the South Rocky Mountain Wetland Region. Wetlands characteristic of this region include flat bogs, horizontal fens, floodplain marshes with shallow basin marshes occurring in valleys and small basin fens and basin bogs occurring in alpine areas (Government of Canada 1986). • The Hinton Pump Station is located in the Montane Natural Subregion of the Rocky Mountain Natural Region. Wetlands characteristic of this natural subregion include treed fens with some bogs and open fens (Natural Regions Committee 2006b). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • A ground-based wetland survey was conducted on July 29, 2013 for the Hinton Pump Station. The 2013 wetland field survey confirmed that no wetlands are located within the Hinton Pump Station. An artificially-created dugout was identified within the pump station footprint expansion but determined not to be a naturally-occurring wetland. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Hinton Pump Station. • The Hinton Pump Station is located within a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • The Hinton Pump Station is not located within the 1,000 m setback of provincially identified colonial nesting bird waterbodies or the 800 m setback of provincially identified trumpeter swan waterbodies (AESRD 2010-2012).
Vegetation	• The Hinton Pump Station is situated within the boundaries of the Western Alberta Upland Ecoregion of the Boreal Plains Ecozone. It is characterized by mixed forests of lodgepole pine, white spruce, balsam poplar, trembling aspen and paper birch. Conifers are more prevalent at higher elevations in the foothills, while the lower plains section is dominated by aspen (Ecological Stratification Working Group 1995). • The Hinton Pump Station is located in the Montane Natural Subregion of the Rocky Mountain Natural Region. The Montane Natural Subregion is dominated by closed forests of lodgepole pine, Douglas-fir, trembling aspen and white spruce. Typical understory communities are dominated by shrubs and grasses. Deciduous forests occur on fluvial fans, terraces and floodplains. Open grasslands occur on dry and exposed sites and are dominated by various grasses (Natural Regions Committee 2006a). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Hinton Pump Station. • Records of rare plant observations within 5 km of the Hinton Pump Station were acquired from the ACIMS (2013) database. Three provincially-listed (ACIMS) record were found within the boundaries of the Vegetation LSA: *Brachythecium frigidum*; *Bryum algovicum*; and *Desmatodon heimii*. • A ground-based vegetation survey was conducted on August 15, 2013. Dominant communities observed during the 2013 vegetation survey consist of a regenerating forest of white spruce and balsam poplar, and a seeded area dominated by agronomic grasses. No rare plants or rare ecological communities were observed at the Hinton Pump Station during the 2013 vegetation survey.

TABLE 6.1-5 Cont'd

Environmental Elements	Summary of Considerations
Vegetation (cont'd)	• Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications. • During the 2013 vegetation survey, three Noxious weed species were observed: Canada thistle; ox-eye daisy; and perennial sow-thistle. No Prohibited Noxious weeds were observed.
Wildlife and Wildlife Habitat	• The Hinton Pump Station is located on industrial and forested lands. Dominant communities consist of a regenerating forest of white spruce and balsam poplar, and a seeded area dominated by agronomic grasses. • The Hinton Pump Station is not located within or adjacent to any Environmentally Significant Areas (ATPR 2009), provincial parks or protected areas (ATPR 2012), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), or World Biosphere Reserves (UNESCO 2013). • The Hinton Pump Station is located in a Special Access Area (AESRD 2013b). • The Hinton Pump Station is located in a secondary Grizzly Bear Zone (Grande Cache population unit) and is located approximately 45 m northwest of a core Grizzly Bear Zone (Yellowhead population unit) (AESRD 2013b). • An artificially-created dugout was identified within the pump station footprint expansion but was determined not to be a naturally-occurring wetland. • The Hinton Pump Station is located in a DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013). • A national Environmentally Significant Area (No. 20) is located approximately 2 km southeast of the Hinton Pump Station (ATPR 2009). • The Wildhorse Lake Provincial Recreation Area is approximately 2 km west of the Hinton Pump Station (ATPR 2012). • The Hinton Pump Station is located in WMU 438 (AESRD 2012b). • Long-toed salamander larvae were identified in a wetland during field work conducted for wetlands on July 29, 2013. The wetland is located 30 m north of the Hinton Pump Station and will not be disturbed by the proposed expansion. Long-toed salamander were also recorded at the Hinton Pump Station during previous work completed in 2005 (TERA Westland 2005). • Long-toed salamander breeding ponds have a recommended year-round 200 m setback (Government of Alberta 2013). Given the location of the wetland in relation to the pump station, the setback cannot be adhered to and AESRD will be consulted to discuss mitigation for the long-toed salamander breeding pond. • A supplemental wildlife survey will be conducted (see Section 9.0).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Hinton Pump Station were acquired from the ACIMS (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species were identified as having the potential to occur in the vicinity of the Hinton Pump Station (ASRD 2010, AESRD 2012a, COSEWIC 2013, Environment Canada 2012): – barred owl (provincial: Sensitive; Alberta Endangered Species Conservation Committee [ESCC]: Special Concern); – common nighthawk (*SARA*: Threatened, COSEWIC: Threatened, provincial: Sensitive); – olive-sided flycatcher (*SARA*: Threatened, COSEWIC: Threatened, provincial: May Be At Risk); – grizzly bear (*SARA*: no status, COSEWIC: Special Concern, provincial: At Risk, Alberta *Wildlife Act* and *Wildlife Regulation:* Threatened); – little brown myotis (COSEWIC: Endangered, provincial: Secure); – northern myotis (COSEWIC: Endangered, provincial: May be at Risk); – long-toed salamander (provincial: Sensitive, Alberta ESCC: Special Concern); and – western toad (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Sensitive). • A search of the AESRD FWMIS database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species within 2 km of the Hinton Pump Station (AESRD 2013c): – grizzly bear (*SARA*: no status, COSEWIC: Special Concern, provincial: At Risk, Alberta *Wildlife Act* and *Wildlife Regulation:* Threatened); – long-toed salamander (provincial: Sensitive, Alberta ESCC: Special Concern); and – western toad (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Sensitive). • A supplemental survey will be conducted (see Section 9.0).

6.1.6 Jasper Pump Station

The existing Jasper Pump Station is located at NW 2-46-1 W6M. This facility is located on lands leased by Trans Mountain in the Jasper National Park Region and within the boundary of the Municipality of Jasper. Current land use at and around this facility site is primarily industrial and forested. No disturbance of previously undisturbed lands is proposed at the Jasper Pump Station; all activities are confined to the existing station boundaries. Two existing 2,500 HP pump units at the Jasper Pump Station will be relocated within the station. Access to the Jasper Pump Station is via Highway 16. Table 6.1-6 provides a summary of the environmental elements and considerations for the Jasper Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Jasper Pump Station is shown on Figure 6.1-6.

TABLE 6.1-6

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE JASPER PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Jasper Pump Station is located within the Rocky Mountains Physiographic Region (Natural Regions Committee 2006a, Pettapiece 1986). • The Jasper Pump Station is underlain by the Fairholme Group, and Sassenach, Palliser and Banff Formations, which consist of dolomite, limestone, shale, sandstone and siltstone (Hamilton *et al.* 1999). • The surficial geology beneath the site is mapped as glaciofluvial deposits (Holland and Coen 1983). • There are no areas of permafrost within the area of Jasper Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Jasper Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). No earthquakes have been recorded in the vicinity of the pump station (NRCan 2013b). • The topography in the area of the Jasper Pump Station is relatively flat and the elevation is approximately 1,340 m above sea level. • Where activities are planned within the Jasper Pump Station, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing station. Wind erosion risk for unprotected soils in the vicinity of the Jasper Pump Station is considered negligible and unrated by NRCan (NRCan 2010d). • A description of the climate for the Montane Natural Subregion is provided in Section 5.1.1. • Meteorological data were obtained from an Environment Canada meteorological station (3053520) in Jasper, Alberta (Environment Canada 2013a). The data was taken approximately 8 km south-southwest of Jasper Pump Station and is provided in Table 6.1-5. • No major tornadoes or hailstorms have been recorded in the vicinity of Jasper Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Jasper Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • The CLI has not rated the soils in the vicinity of the Jasper Pump Station. • Historical spills have been recorded at the Jasper Pump Station. Ongoing monitoring is being conducted by operations. Soils to be disturbed will be tested prior to construction. If contamination is encountered, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants, hydraulic fuels and methyl tertiary butyl ether (MTBE).
Water Quality and Quantity	• The Jasper Pump Station is located within the Athabasca River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • Land use in the area is noted as industrial. The terrain is reported as sloping slightly from west to east. • Groundwater flow likely follows topography towards the Athabasca River located approximately 500 m to the east. • The surficial geology beneath the site is mapped as glaciofluvial deposits (Holland and Coen 1983). • Four water well records occur near the site and within the Water Quantity and Quality LSA; these indicate groundwater depths of 5-28 m bgl. • One water supply well (possibly ID #442074) owned by ATCO Electric Ltd. is located within the Water Quality and Quantity LSA (AESRD 2013a) withdrawing water from 37 m bgl. • The Jasper Pump Station does not overlie any mapped aquifers. • According to O'Rourke (2000), there is historical contamination from a spill of 1,200 L Jet B fuel from underground storage tank at the Jasper Pump Station in 1992 and a release of petroleum containing MTBE in 1995 resulting in apparent contamination of an ATCO well. MTBE was noted in an off-site well in 1999 (O'Rourke 2000). Remediation is ongoing and, as of 2012, MTBE concentrations were less than the detection limit in the ATCO water well (WNM Environmental 2012).
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Jasper Pump Station are estimated to be 1.8 tonnes per year. • Air quality in the area surrounding the Jasper Pump Station is expected to be mostly influenced by vehicle traffic emissions along Highway 16, the Jasper Airport and a nearby power generation plant.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Jasper Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Jasper Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• No increase in sound emissions is expected from the Project at the Jasper Pump Station during operations and, therefore, detailed information on sound emissions is not warranted as per Table A-1 of the NEB *Filing Manual*.

TABLE 6.1-6 Cont'd

Environmental Elements	Summary of Considerations
Fish and Fish Habitat	• The Jasper Pump Station is located within the Athabasca River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Jasper Pump Station is situated within the boundaries of the Western Alberta Upland Ecoregion of the Boreal Plains Ecozone. Marshes and bogs are common within this ecoregion (Ecological Stratification Working Group 1995). • The Jasper Pump Station is also located within the South Rocky Mountain Wetland Region. Wetlands characteristic of this region include flat bogs, horizontal fens, floodplain marshes with shallow basin marshes occurring in valleys and small basin fens and basin bogs occurring in alpine areas (Government of Canada 1986). • The Jasper Pump Station is located in the Montane Natural Subregion of the Rocky Mountain Natural Region. Wetlands characteristic of this natural subregion include treed fens with some bogs and open fens (Natural Regions Committee 2006b). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Jasper Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013), Migratory Bird Sanctuaries (Environment Canada 2013b) or DUC Priority Areas (DUC 2013) located within the Wetland LSA surrounding the Jasper Pump Station.
Vegetation	• The Jasper Pump Station is situated within the boundaries of the Western Alberta Upland Ecoregion of the Boreal Plains Ecozone. It is characterized by mixed forests of lodgepole pine, white spruce, balsam poplar, trembling aspen and paper birch. Conifers are more prevalent at higher elevations in the foothills, while the lower plains section is dominated by aspen (Ecological Stratification Working Group 1995). • The Jasper Pump Station is located in the Montane Natural Subregion of the Rocky Mountain Natural Region. The Montane Natural Subregion is dominated by closed forests of lodgepole pine, Douglas-fir, trembling aspen and white spruce. Typical understory communities are dominated by shrubs and grasses. Deciduous forests occur on fluvial fans, terraces and floodplains. Open grasslands occur on dry and exposed sites and are dominated by various grasses (Natural Regions Committee 2006a). • The Jasper Pump Station is located in Jasper National Park (ATPR 2012). • The Jasper Pump Station is located in an international Environmentally Significant Area (No. 23) (ATPR 2009). • Records of rare plant observations within 5 km of the Jasper Pump Station were acquired from the ACIMS (2013) database. Eleven provincially-listed (ACIMS) species record were found within the boundaries of the Vegetation LSA: *Cirriphyllum cirrosum*; Crawe's sedge; *Didymodon nigrescens*; *Geranium erianthum*; *Hygrohypnum smithii*; lens-fruited sedge; *Lophozia excisa*; *Myriospora heppii*; *Orthotrichum affine*; red leaf moss; and short-beaked rigid screw moss. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Jasper Pump Station is located adjacent to an existing pump house and valve assembly on industrial lands. The existing access and power supply is sufficient for Project needs. All work will occur within the existing fenced area and no native vegetation would be directly disturbed within the site boundaries. • The Jasper Pump Station is located in Jasper National Park (ATPR 2012). • The Jasper Pump Station is located in an international Environmentally Significant Area (No. 23) (ATPR 2009).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Jasper Pump Station were acquired from the ACIMS (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • A search of the AESRD FWMIS database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species within 2 km of the Jasper Pump Station (AESRD 2013c): – western toad (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Sensitive). • Given that the Jasper Pump Station is an existing facility and all work will occur within the existing fenced area on previously disturbed land, the Jasper Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.7 Rearguard Pump Station

The existing Rearguard Pump Station is located at d-068-K/083-D-14 at RK 498.3 on lands owned by Trans Mountain in the Regional District of Fraser-Fort George (RDFFG). The expansion of the Rearguard Pump Station will require the acquisition of approximately 0.7 ha of new Crown land adjacent to and to the east of existing Trans Mountain lands. Two 5,000 HP pump units will be added at the site. The existing access road to the Rearguard Pump Station will be modified for the Project. Table 6.1-7 provides a summary of the environmental elements and considerations for the Rearguard Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Rearguard Pump Station is shown on Figure 6.1-7.

TABLE 6.1-7

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE REARGUARD PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Rearguard Pump Station is located within the Rocky Mountains Physiographic Region, which is characterized by structurally-controlled moderately wide valleys surrounded by rugged alpine mountains featuring relict glacial landforms (Holland 1976). • The Rearguard Pump Station is underlain by the Middle Member of the Miette Group (Journeay *et al.* 2000a, Murphy 2007). This unit is composed of massive to graded, thick bedded, feldspathic, turbitic sandstones and conglomeratic sandstones (Glass 1990). • The surficial geology beneath the site is mapped as predominantly glaciofluvial and lacustrine sediments (BGC Engineering Inc. 2013a). • There are no areas of permafrost within the area of the Rearguard Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Rearguard Pump Station. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Rearguard Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). The site is located near suspected post-glacial faults within the Rocky Mountain trench (BGC Engineering Inc. 2013b). The historical earthquake record shows clusters of small to moderate (up to magnitude 6) earthquakes. The largest of these include a magnitude 6 earthquake near Valemount in 1918 and a magnitude 5.6 earthquake near Prince George in 1986 (Halchuk 2009, Lamontagne *et al.* 2007). Refer to the Seismic Assessment Desktop Study of Volume 4A for additional information. • The topography in the area of the Rearguard Pump Station is relatively flat and the elevation is approximately 810 m above sea level. • Activities are planned within the Rearguard Pump Station at industrial and disturbed forested areas and require approximately 0.7 ha of new land outside existing Trans Mountain lands to the east. Wind erosion risk for unprotected soils in the vicinity of the Rearguard Pump Station is considered negligible and unrated by NRCan (NRCan 2010d). • A description of the climate for the Sub-Boreal Spruce (SBS) Biogeoclimatic (BGC) Zone is provided in Section 5.1.2. • Meteorological data from Environment Canada's Blue River Airport Station, located approximately 100 km south of Rearguard Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of Rearguard Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Project activities will cause some disturbance to soil outside of the existing fenceline of the Rearguard Pump Station to the east. The current Rearguard Pump Station has been previously disturbed and contains pumps, buildings and other equipment. • A soil survey at the Rearguard Pump Station was conducted in 2005 for the Trans Mountain Pump Station Expansion Project. Well to rapidly-drained Eluviated Eutric Brunisols developed on gravelly sandy loam or gravelly loam textured glaciofluvial material (Rearguard soils) occurs throughout the site. These soils are highly disturbed south of the existing pipeline. Rearguard soils are highly susceptible to wind erosion (Mentiga 2005b). • Soil capability for agriculture is generally low (Classes 5 and 6) due to climatic and soil texture limitations as based on the BC Land Inventory (1973). • No contamination is anticipated at the Rearguard Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented.
Water Quality and Quantity	• The Rearguard Pump Station is located in the Upper Fraser River Watershed of the Fraser River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain is reported to be generally level. Groundwater flow likely follows topography southwest towards the Fraser River. • The surficial geology beneath the site is mapped as predominantly Glaciofluvial and lacustrine sediments (BGC Engineering 2013a). • No water supply wells are mapped within the site boundary or within the surrounding Water Quality and Quantity LSA (BC Ministry of Environment [MOE] 2013a). • Groundwater levels in the area are expected to be moderately deep based on water well records identified east and west of the station. • The Rearguard Pump Station does not overlie any mapped aquifers (BC MOE 2013a).
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Rearguard Pump Station are estimated to be 1.7 tonnes per year. • Air quality in the area surrounding the Rearguard Pump Station is expected to be mostly vehicle traffic emissions along Highway 16 and Highway 5 and a nearby wood product facility.

TABLE 6.1-7 Cont'd

Environmental Elements	Summary of Considerations
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Rearguard Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Rearguard Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 16, Highway 5, surrounding arterial roadways and natural sound (*e.g.*, wind, wildlife). • No receptors were identified within the Acoustic Environment LSA. The 1.5 km LSA boundary will be used for compliance assessment. • ASL in the absence of regulated energy facilities ranges between 35-40 dBA at night and 45-50 dBA during the day based on BC Oil and Gas Commission (OGC) *Noise Control Best Practices Guideline* (BC OGC 2009). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Rearguard Pump Station complies with the BC OGC *Noise Control Best Practices Guideline* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Rearguard Pump Station is located in the Upper Fraser River Watershed of the Fraser River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Rearguard Pump Station is situated within the boundaries of the Eastern Continental Ranges Ecoregion of the Montane Cordillera Ecozone. Wetlands in this ecoregion tend to be restricted to mountain slopes where non-forested bogs, marshes and swamps occur (Ecological Stratification Working Group 1995). • The Rearguard Pump Station is also located within the South Rocky Mountain Wetland Region. Wetlands characteristic of this region include flat bogs, horizontal fens, floodplain marshes with shallow basin marshes occurring in valleys and small basin fens and basin bogs occurring in alpine areas (Government of Canada 1986). • The Rearguard Pump Station is located within the SBS BGC Zone of BC. In this BGC Zone, wetlands are common and consist of marshes, shrub and treed fens, and swamps with the occasional bog (BC Ministry of Forests [MOF] 1998a, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Rearguard Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013), Migratory Bird Sanctuaries (Environment Canada 2013b) or DUC Priority Areas (DUC 2013) located within the Wetland LSA surrounding the Rearguard Pump Station.
Vegetation	• The Rearguard Pump Station is situated within the boundaries of the Eastern Continental Ranges Ecoregion of the Montane Cordillera Ecozone. This ecoregion is characterized by coniferous forests of lodgepole pine, Engelmann spruce and alpine fir. In the warmest and driest areas of this Ecoregion, stands of Douglas-fir intermixed with trembling aspen and grasslands are common, while in cooler areas, open stands of alpine fir are found. The alpine vegetation is characterized by dwarf shrubs with sedges and herbs occurring on warmer sites (Ecological Stratification Working Group 1995). • The Rearguard Pump Station is located within the SBS BGC Zone of BC which is dominated by upland coniferous forests of subalpine fir and hybrid white spruce. Lodgepole pine, trembling aspen, paper birch, Douglas-fir and black spruce are also dominant forest species (BC MOF 1998a, Meidinger and Pojar 1991). • Rearguard Falls Provincial Park is located within the Vegetation LSA, approximately 0.5 km from the Rearguard Pump Station. • Records of rare plant observations within 5 km of the Rearguard Pump Station were acquired from the BC Conservation Data Centre (BC CDC) (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • The proposed expansion at the Rearguard Pump Station is assumed to be on native vegetation based upon a review of satellite imagery and the professional judgement of the vegetation team. Mitigation contained in the Facilities EPP of Volume 6C is considered adequate for expected conditions and a supplemental vegetation survey conducted prior to construction will confirm the predictions of potential effects on the native vegetation in this area. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.

TABLE 6.1-7 Cont'd

Environmental Elements	Summary of Considerations
Wildlife and Wildlife Habitat	• The Rearguard Pump Station lies within the Robson Valley Land and Resource Management Plan (LRMP) region (BC Ministry of Forests, Lands and Natural Resource Operations [MFLNRO] 2008a). • The Rearguard Pump Station is located on industrial and disturbed forested lands. Activities at the Rearguard Pump Station will occur on previously cleared and disturbed land. • The Rearguard Pump Station is not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Rearguard Pump Station is not in a DUC Priority Area (DUC 2013). • Rearguard Falls Provincial Park is approximately 0.5 km from the Rearguard Pump Station (BC MFLNRO 2008b). • The Rearguard Pump Station is located in WMU 7-3 (BC Integrated Land Management Bureau [ILMB] 2006).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Rearguard Pump Station were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Rearguard Pump Station (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – barn swallow (COSEWIC: Threatened, provincial: Blue); – common nighthawk (*SARA*: Threatened, COSEWIC: Threatened, provincial: Yellow); – olive-sided flycatcher (*SARA*: Threatened, COSEWIC: Threatened, provincial: Blue); – fisher (provincial: Blue); – grizzly bear (COSEWIC: Special Concern, provincial: Blue); – little brown myotis (COSEWIC: Endangered, provincial: Yellow); – northern myotis (COSEWIC: Endangered, provincial: Blue); and – wolverine (*luscus* subspecies) (COSEWIC: Special Concern, provincial: S3, Blue, Priority 2). • A search of the BC CDC database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Rearguard Pump Station (BC CDC 2012, 2013). • Given that the Rearguard Pump Station is an existing facility and that any expansion will occur onto previously-cleared and disturbed land, the Rearguard Pump Station is not considered suitable habitat for wildlife species at risk.

6.1.8 Blue River Pump Station

The existing Blue River Pump Station is located at a-035-F/083-D-03 at RK 614.7 on lands owned by Trans Mountain in the Thompson-Nicola Regional District (TNRD). Current land use at and around this facility site is industrial. All work will be conducted within the existing disturbed fenced area and no native vegetation would be directly disturbed within the site boundaries. No disturbance of previously undisturbed lands is proposed at the Blue River Pump Station. Three new 5,000 HP pump units will be added and the existing pump building at the Blue River Pump Station will be deactivated. Access to the Blue River Pump Station is via Highway 5. Table 6.1-8 provides a summary of the environmental elements and considerations for the Blue River Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Blue River Pump Station is shown on Figure 6.1-8.

TABLE 6.1-8

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE BLUE RIVER PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Blue River Pump Station is located within the Columbia Mountains Physiographic Region, which is characterized by wide U-shaped main valleys, narrow hanging steeply incised tributary valleys, rugged alpine ranges, fluvial terraces, fan and relict glacial landforms (Demarchi 2011, Holland 1976). • The Blue River Pump Station is predominantly underlain by gneisses and other metamorphic rocks (Journeay *et al.* 2000a, Murphy 2007). • The surficial geology beneath the site is mapped as predominantly fluvial (Tipper 1971). • There are no areas of permafrost within the area of the Blue River Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Blue River Pump Station. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Blue River Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). Several minor earthquakes (magnitude 3) have been recorded in the area (NRCan 2013b). • The topography in the area of Blue River Pump Station is flat and the elevation is approximately 690 m above sea level. • Where activities are planned within Blue River Pump Station, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing station. Wind erosion risk for unprotected soils in the vicinity of Blue River Pump Station is considered negligible and unrated by NRCan (NRCan 2010d). • A description of the climate for the Interior Cedar-Hemlock (ICH) BGC Zone is provided in Section 5.1.2. • Meteorological data from Environment Canada's Blue River Airport Station, located approximately 1 km northeast of Blue River Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of Blue River Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Blue River Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • The general area is dominated by Humo-Ferric Podzolic soils. This soil type is characterized by coarse to moderately-coarse textured, very permeable glacial till or colluvium derived mainly from igneous and metamorphic rocks such as granodiorites, gneisses and schists (Valentine *et al.* 1978). • The CLI has not rated the soils in the vicinity of the Blue River Pump Station. • No contamination is anticipated at the Blue River Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented.
Water Quality and Quantity	• The Blue River Pump Station is located in the Upper North Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain is generally level. Groundwater flow direction is likely toward Eleanor Lake approximately 150 m to the east-northeast. • The surficial geology beneath the site is mapped as predominantly fluvial (Tipper 1971). • No water supply wells are mapped within the site boundary, however, one well is located within the surrounding Water Quality and Quantity LSA (BC MOE 2013a). • Groundwater levels in the area are expected to be moderately deep based on water well records identified southwest of the station. • The Blue River Pump Station does not overlie any mapped aquifers (BC MOE 2013a).
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Blue River Pump Station are estimated to be 1.7 tonnes per year. • Air quality in the area surrounding the Blue River Pump Station, based on the nearby emission sources, is expected to be generally very good with some influence from the Community of Blue River and the Blue River Airport.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Blue River Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Blue River Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Although new pump units will be added, the existing pump units of equivalent sound emissions will be deactivated. No increase in sound emissions is expected from the Project at the Blue River Pump Station during operations and, therefore, detailed information on sound emissions is not warranted as per Table A-1 of the NEB *Filing Manual*.
Fish and Fish Habitat	• The Blue River Pump Station is located in the Upper North Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.

TABLE 6.1-8 Cont'd

Environmental Elements	Summary of Considerations
Wetland Loss or Alteration	• The Blue River Pump Station is situated within the boundaries of the Columbia Mountains and Highlands Ecoregion of the Montane Cordillera Ecozone. Wetlands in this ecoregion tend to be restricted to mountain slopes where non-forested bogs, marshes and swamps occur (Ecological Stratification Working Group 1995). • The Blue River Pump Station is also located within the South Interior Mountain Wetland Region. Wetlands characteristic of this region include flat bogs, basin bogs and shallow basin marshes. Within alpine areas, small basin fens and basin bogs can be found (Government of Canada 1986). • The Blue River Pump Station is located within the ICH BGC Zone of BC. In this BGC Zone, wetlands are not common due to the mountainous terrain. However, marshes associated with lakes and streams in valley bottoms tend to be more common along with small swamps and transitional bogs and fens (BC MOF 1996a, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Blue River Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013), Migratory Bird Sanctuaries (Environment Canada 2013b) or DUC Priority Areas (DUC 2013) located within the Wetland LSA surrounding the Blue River Pump Station.
Vegetation	• The Blue River Pump Station is located within the boundaries of the Columbia Mountains and Highlands Ecoregion of the Montane Cordillera Ecozone. This ecoregion is characterized by mature forests of western hemlock and western redcedar in major valleys, with Douglas-fir, western white pine, and western larch occurring less frequently. The subalpine areas are characterized by Engelmann spruce, alpine fir and lodgepole pine stands (Ecological Stratification Working Group 1995). • The Blue River Pump Station is located within the ICH BGC Zone of BC. The ICH BGC Zone is dominated by western redcedar, western hemlock, white spruce, Engelmann spruce, spruce hybrids and subalpine fir. Western larch, Douglas-fir, lodgepole pine, trembling aspen, paper birch, ponderosa pine and western white pine are also common in the central and southern areas of this zone. Black cottonwood are common in wet areas (BC MOF 1996a, Meidinger and Pojar 1991). • The Blue River Pine Provincial Park, located within the Vegetation LSA, lies approximately 0.7 km northeast of the Blue River Pump Station. • Records of rare plant observations within 5 km of the Blue River Pump Station were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Blue River Pump Station lies within in the Kamloops LRMP region (BC MFLNRO 2008a). • The Blue River Pump Station is located on industrial lands. • The Blue River Pump Station is not located within or adjacent to any provincial parks or protected areas (the nearest park is located 0.7 km northeast) (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a) or Wildlife Habitat Areas (BC MOE 2005b). • The Blue River Pump Station is not in a DUC Priority Area (DUC 2013). • The Blue River Pine Provincial Park is approximately 0.7 km northeast of the Blue River Pump Station (BC MFLNRO 2008b). • The Blue River Pump Station is located in WMU 3-40 (BC ILMB 2006).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Blue River Pump Station were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Blue River Pump Station (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): − barn swallow (COSEWIC: Threatened, provincial: Blue); and − little brown myotis (COSEWIC: Endangered, provincial: Yellow). • A search of the BC CDC database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Blue River Pump Station (BC CDC 2012, 2013). • Given that the Blue River Pump Station is an existing facility and all work will occur within the existing fenced area on previously disturbed land, the Blue River Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.9 Blackpool Pump Station

The existing Blackpool Pump Station is located at c-073-B/092-P-09 at RK 736.8 on lands owned by Trans Mountain in the TNRD. Current land use at and around this facility site is industrial. No disturbance of previously undisturbed lands is proposed at the Blackpool Pump Station. Three 5,000 HP pump units will be added at the site. Access to the Blackpool Pump Station is via Highway 5. Table 6.1-9 provides a summary of the environmental elements and considerations for the Blackpool Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Blackpool Pump Station is shown on Figure 6.1-9.

TABLE 6.1-9

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE BLACKPOOL PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Blackpool Pump Station is located within the Interior Plateau Physiographic Region, which is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans, and cones (Demarchi 2011, Holland 1976). • The Blackpool Pump Station is predominantly underlain by gneisses and other metamorphic rocks (Journeay *et al.* 2000b). • The surficial geology beneath the site is mapped as predominantly fluvial (Tipper 1971). SEACOR Environmental Inc. (2005) mapped the materials beneath the site as consisting of gravel and sand fill to 1.5 m bgl then sand to 2.4 m bgl; gravel was encountered to a depth of 10.7 m bgl (depth of investigation). • There are no areas of permafrost within the area of the Blackpool Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Blackpool Pump Station. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Blackpool Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). No earthquakes have been recorded in the area (NRCan 2013b). • The topography in the area of Blackpool Pump Station is relatively flat and the elevation is approximately 390 m above sea level. • Where activities are planned within Blackpool Pump Station, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing station. NRCan considers unprotected soils in the vicinity of Blackpool Pump Station to have low wind erosion risk with low climatic sensitivity (NRCan 2010d). • A description of the climate for the Interior Douglas-Fir (IDF) BGC Zone is provided in Section 5.1.2. • Meteorological data from Environment Canada's Blue River Airport Station, located approximately 90 km northeast of the Blackpool Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of the Blackpool Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Blackpool Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • A soil survey at the Blackpool Pump Station was conducted in 2005 for the Trans Mountain Pump Station Expansion Project. Well to imperfectly-drained Orthic Regosols and Orthic Humic Regosols developed on sandy loam to loamy sand textured, stone-free fluvial sediments soils are the dominant soils in undisturbed areas (Blackpool soils). Poorly-drained depressional areas consist of Rego Gleysols developed on loam to silty clay loam textured fluvial material (Mosquito soils). These soils are of minor extent occupying a meander scar in the northeast portion of the site. A large area in the fenced compound consists of disturbed land (*i.e.,* land that has been disturbed by prior construction activities). It may have gravel added to the surface or may have been previously graded. In general, disturbed lands do not have any salvageable topsoil (Mentiga 2005b). • Soil capability for agriculture at the Blackpool Pump Station is low (Class 5) due to climatic and soil textural limitations as based upon BC Land Inventory (1973). • A historical spill was recorded at the Blackpool Pump Station. Ongoing groundwater monitoring and sampling programs are in place. Soils to be disturbed will be tested prior to construction. If contaminated soil is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented.
Water Quality and Quantity	• The Blackpool Pump Station is located in the Lower North Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain at the Blackpool Pump Station is generally level. Groundwater flow likely follows topography south and southwest towards the North Thompson River. • The surficial geology beneath the site is mapped as predominantly fluvial (Tipper 1971). SEACOR Environmental Inc. (2005) mapped the materials beneath the site as consisting of gravel and sand fill to 1.5 m bgl then sand to 2.4 m bgl; gravel was encountered to a depth of 10.7 m bgl (depth of investigation). • No water supply wells are mapped within the site boundary and one well is located within the surrounding Water Quality and Quantity LSA (BC MOE 2013a). • Monitoring wells at the site indicate groundwater levels ranged from 2.7-3.5 m bgl. • The Blackpool Pump Station does not overlie any mapped aquifers (BC MOE 2013a). • AMEC Earth & Environmental (AMEC) (2012, 2013) reported that historical sampling revealed hydrocarbon impacts were present in wells BH08-03, BH08-04, BH11-18. No defined source was indicated for the contamination (AMEC 2013). Horizontal delineation indicated that there was no off-site migration of the contamination. Recommended ongoing monitoring (AMEC 2013) has been conducted.
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Blackpool Pump Station are estimated to be 1.7 tonnes per year. • Air quality in the area near the Blackpool Pump Station, based on the nearby emission sources, is expected to be generally very good with some influence from vehicle traffic emissions along Highway 5 and natural emissions from vegetation.

TABLE 6.1-9 Cont'd

Environmental Elements	Summary of Considerations
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Blackpool Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Blackpool Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 5 and surrounding arterial roadways and natural sound (*e.g.*, wind, wildlife, river). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 150 m to the north of the fenceline of the Blackpool Pump Station. • ASL in the absence of regulated energy facilities ranges between 35-40 dBA at night and 45-50 dBA during the day based on BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Blackpool Pump Station complies with the BC OGC *Noise Control Best Practices Guideline* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Blackpool Pump Station is located in the Lower North Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Blackpool Pump Station is situated within the boundaries of the Columbia Mountains and Highlands Ecoregion of the Montane Cordillera Ecozone. Wetlands in this ecoregion tend to be restricted to mountain slopes where non-forested bogs, marshes and swamps occur (Ecological Stratification Working Group 1995). • The Blackpool Pump Station is also located within the South Interior Mountain Wetland Region. Wetlands characteristic of this region include flat bogs, basin bogs and shallow basin marshes. Within alpine areas, small basin fens and basin bogs can be found (Government of Canada 1986). • The Blackpool Pump Station is located within the IDF BGC Zone of BC. In this BGC Zone, wetlands are often found in depressions, around open water, small streams and drainage channels. Wetlands types include fens, marshes as well as shrubby swamps (BC MOF 1996b, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • It was determined during the helicopter reconnaissance and satellite imagery interpretation that there is one wetland, a Riparian Marsh (deep marsh), located along the north boundary of the Blackpool Pump Station boundary. This wetland is not anticipated to be disturbed during the pump station construction. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013), Migratory Bird Sanctuaries (Environment Canada 2013b) or DUC Priority Areas (DUC 2013) located within the Wetland LSA surrounding the Blackpool Pump Station.
Vegetation	• The Blackpool Pump Station is located within the boundaries of the Columbia Mountains and Highlands Ecoregion of the Montane Cordillera Ecozone. This ecoregion is characterized by mature forests of western hemlock and western redcedar in major valleys, with Douglas-fir, western white pine, and western larch occurring less frequently. The subalpine areas are characterized by Engelmann spruce, alpine fir and lodgepole pine stands (Ecological Stratification Working Group 1995). • The Blackpool Pump Station is located within the IDF BGC Zone of BC. The IDF BGC Zone is dominated by closed, mature forests of Douglas-fir. Mixed stands of Douglas-fir, lodgepole pine, ponderosa pine, white spruce, western redcedar and trembling aspen are also common. Grassland communities also occur in parts of the zone (Meidinger and Pojar 1991). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Blackpool Pump Station. • Records of rare plant observations within 5 km of the Blackpool Pump Station were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.

TABLE 6.1-9 Cont'd

Environmental Elements	Summary of Considerations
Wildlife and Wildlife Habitat	• The Blackpool Pump Station lies within the Kamloops LRMP region (BC MFLNRO 2008a). • The Blackpool Pump Station is located on industrial lands. • The Blackpool Pump Station is not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Blackpool Pump Station is not in a DUC Priority Area (DUC 2013). • The Blackpool Pump Station is located in WMU 3-39 (BC ILMB 2006).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Blackpool Pump Station were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Blackpool Pump Station (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – common nighthawk (*SARA*: Threatened, COSEWIC: Threatened, provincial: Yellow); – little brown myotis (*SARA*: no status, COSEWIC: Endangered, provincial: Yellow); and – Townsend's big-eared bat (*SARA*: no status, COSEWIC: no status, provincial: Blue). • A search of the BC CDC database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Blackpool Pump Station (BC CDC 2012, 2013). • Given that the Blackpool Pump Station is an existing facility and all work will occur within the existing fenced area, the Blackpool Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.10 Darfield Pump Station

The existing Darfield Pump Station is located at d-075-B/092-P-08 at RK 769 on lands owned by Trans Mountain in the TNRD. Current land use at and around this facility site is industrial and agricultural. The expansion of the Darfield Pump Station will be both within the existing disturbed fenced area and west onto cultivated agricultural lands and require a small amount (0.07 ha) of land. New scraper facilities (receiving) will be installed at the site. Access to the Darfield Pump Station is via Highway 5. Table 6.1-10 provides a summary of the environmental elements and considerations for the Darfield Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Darfield Pump Station is shown on Figure 6.1-10.

TABLE 6.1-10

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE DARFIELD PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Darfield Pump Station is located within the Interior Plateau Physiographic Region, which is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans, and cones (Demarchi 2011, Holland 1976). • The Darfield Pump Station is predominantly underlain by igneous and metamorphic as well as potential sandstones and carbonates (Monger and McMillan 1989). • The surficial geology beneath the site is mapped as predominantly fluvial (Tipper 1971). • There are no areas of permafrost within the area of the Darfield Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Darfield Pump Station. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Darfield Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). No earthquakes have been recorded in the area (NRCan 2013b). • The topography in the area of the Darfield Pump Station is relatively flat and the elevation is approximately 390 m above sea level. • Where activities are planned within the Darfield Pump Station, most soils have been disturbed for industrial use, however, approximately 0.07 ha of new land currently under agricultural use will be required outside the existing fenceline. NRCan considers unprotected soils in the vicinity of the Darfield Pump Station to have low wind erosion risk with low climatic sensitivity (NRCan 2010d). • A description of the climate for the IDF BGC Zone is provided in Section 5.1.2. • Meteorological data from Environment Canada's Darfield Station, located approximately 1.8 km south of the Darfield Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of the Darfield Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Project activities will cause some disturbance to soil outside of the existing fenceline of the Darfield Pump Station. The current Darfield Pump Station has been previously disturbed and contains pumps, buildings and other equipment. • Soils in the vicinity of the Darfield Pump Station are dominated by Gray Luvisolic soils (Valentine *et al.* 1978). Luvisolic soils generally have light-coloured, eluvial horizons and have illuvial B horizons in which silicate clay has accumulated. These soils develop characteristically in well to imperfectly-drained sites, in sandy loam to clay, base-saturated parent materials under forest vegetation in subhumid to humid, mild to very cold climates (Agriculture and Agri-Food Canada 1998). • The CLI (1981) has rated the soils in the vicinity of the Darfield Pump Station as having no limitations (Class 1) to crop production. • A historical spill has been recorded at the Darfield Pump Station. Soils to be disturbed will be tested prior to construction. If contamination is encountered, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels. • Clubroot is a soil-borne disease that affects canola and other crops in the mustard family. A small amount of new land currently under agricultural use will be required outside the existing fenceline, however, no occurrences of clubroot have been identified in TNRD (Joshi pers. comm.).
Water Quality and Quantity	• The Darfield Pump Station is located in the Lower North Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain at the Darfield Pump Station is generally level. Groundwater flow likely follows topography east and southeast towards the North Thompson River. • The surficial geology beneath the site is mapped as predominantly fluvial (Tipper 1971). • No water supply wells are mapped within the site boundary or surrounding Water Quality and Quantity LSA (BC MOE 2013a). • Groundwater levels in the area are expected to be moderately deep based on water well records identified south of the station. • The Darfield Pump Station overlies Aquifer #293, a moderately vulnerable sand and gravel deposit (BC MOE 2013a).
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Darfield Pump Station are estimated to be 2.9 tonnes per year. • Air quality in the area around the Darfield Pump Station is expected to be generally very good, with some influence from vehicle traffic emissions along Highway 5.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Darfield Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Darfield Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.

TABLE 6.1-10 Cont'd

Environmental Elements	Summary of Considerations
Acoustic Environment	• No increase in sound emissions is expected from the Project at the Darfield Pump Station during operations and, therefore, detailed information on sound emissions is not warranted as per Table A-1 of the NEB *Filing Manual*.
Fish and Fish Habitat	• The Darfield Pump Station is located in the Lower North Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Darfield Pump Station is situated within the boundaries of the Columbia Mountains and Highlands Ecoregion of the Montane Cordillera Ecozone. Wetlands in this ecoregion tend to be restricted to mountain slopes where non-forested bogs, marshes and swamps occur (Ecological Stratification Working Group 1995). • The Darfield Pump Station is also located within the South Interior Mountain Wetland Region. Wetlands characteristic of this region include flat bogs, basin bogs and shallow basin marshes. Within alpine areas, small basin fens and basin bogs can be found (Government of Canada 1986). • The Darfield Pump Station is located within the IDF BGC Zone of BC. In this BGC Zone, wetlands are often found in depressions, around open water, small streams and drainage channels. Wetlands types include fens, marshes as well as shrubby swamps (BC MOF 1996b, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Darfield Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Darfield Pump Station. • The Darfield Pump Station is located within a DUC Level 3 Priority Area Eastern Boreal Forest (DUC 2013).
Vegetation	• The Darfield Pump Station is located within the boundaries of the Columbia Mountains and Highlands Ecoregion of the Montane Cordillera Ecozone. This ecoregion is characterized by mature forests of western hemlock and western redcedar in major valleys, with Douglas-fir, western white pine, and western larch occurring less frequently. The subalpine areas are characterized by Engelmann spruce, alpine fir and lodgepole pine stands (Ecological Stratification Working Group 1995). • The Darfield Pump Station is located within the IDF BGC Zone of BC. The IDF BGC Zone is dominated by closed, mature forests of Douglas-fir. Mixed stands of Douglas-fir, lodgepole pine, ponderosa pine, white spruce, western redcedar and trembling aspen are also common. Grassland communities also occur in parts of the zone (Meidinger and Pojar 1991). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Darfield Pump Station. • Records of rare plant observations within 5 km of the Darfield Pump Station were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Darfield Pump Station lies within the Kamloops LRMP region (BC MFLNRO 2008a). • The Darfield Pump Station is located on industrial and Agricultural Land Reserve (ALR) lands. • The Darfield Pump Station is not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Darfield Pump Station is located in a DUC Level 3 Priority Area Eastern Boreal Forest (DUC 2013). • The Darfield Pump Station is located in WMU 3-28 (BC ILMB 2006).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Darfield Pump Station were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Darfield Pump Station (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – long-billed curlew (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); – Townsend's big-eared bat (*SARA*: no status, COSEWIC: no status, provincial: Blue); and – rubber boa (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Yellow). • A search of the BC CDC database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Darfield Pump Station (BC CDC 2012, 2013). • Given that the Darfield Pump Station is an existing facility and that expansion will occur within the existing disturbed fenced area and west onto cultivated agricultural lands, the Darfield Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.11 Black Pines Pump Station

The proposed Black Pines Pump Station is a new site located on forested and pasture lands at d-041-K/092-I-16 at RK 811.9. The Black Pines Pump Station is located in the TNRD. The Black Pines Pump Station will require a new land base of approximately 150 m x 150 m (approximately 2.3 ha) for the pump station and substation. The new land is privately owned, treed and within the ALR. Two 2,500 HP pump units and two 5,000 HP pump units will be added at the site. A new 138 kV power line approximately 2.2 km long in a 50 m wide right-of-way will also be installed at the proposed Black Pines site. A short new access road to the site will be constructed. Table 6.1-11 provides a summary of the environmental elements and considerations for the Black Pines Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the proposed Black Pines Pump Station and associated power line are shown on Figure 6.1-11.

TABLE 6.1-11

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE BLACK PINES PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The proposed Black Pines Pump Station, access road and power line are located within the Interior Plateau Physiographic Region, which is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans, and cones (Demarchi 2011, Holland 1976). • The Black Pines Pump Station is predominantly underlain by igneous and metamorphic rock as well as potential sandstones and carbonates (Monger and McMillan 1989). • The surficial geology beneath the site is mapped as predominantly fluvial (Young 1983). • There are no areas of permafrost within the area of the proposed Black Pines Pump Station (refer to Section 5.1.1). • A field reconnaissance was conducted in December 2012 to refine the location of the pump station in consideration of local terrain features and surface geology. The surface materials where the pump station is currently proposed consist of a debris fan. Therefore, further geotechnical assessments will be required at this site to determine the optimum location for the pump station site as well as to determine appropriate mitigation measures to protect the stations from a potential debris flow during operations of the Project. The surface of the preliminary site is sloped, which would require some grading to level the surface for construction and operations of the pump stations. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the proposed Black Pines Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). No earthquakes have been recorded in the area (NRCan 2013b). • The topography in the area of the proposed Black Pines Pump Station is gently sloping and the elevation is approximately 380 m above sea level. • The proposed power line crosses northeast sloping terrain down to the North Thompson River, where it crosses to the east, then extends south along uneven terrain on the west side of Westsyde Road to the proposed Black Pines Pump Station. • The proposed Black Pines Pump Station and access road is located on private, forested land. The proposed power line is located predominately on forested and agricultural private land with the exception of the bed and banks of the North Thompson River. NRCan considers unprotected soils in the vicinity of Black Pines Pump Station to have low wind erosion risk with low climatic sensitivity (NRCan 2010d). • A description of the climate for the Ponderosa Pine (PP) BGC Zone is provided in Section 5.1.2. • Meteorological data from Environment Canada's Kamloops Airport Station, located approximately 30 km southwest of the proposed Black Pines Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of the proposed Black Pines Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• The proposed Black Pines Pump Station is a new site located on forested and tame pasture lands. • Soils in the vicinity of the Black Pines Pump Station are dominated by Gray Luvisolic soils (Valentine *et al.* 1978). Luvisolic soils generally have light-coloured, eluvial horizons and have illuvial B horizons in which silicate clay has accumulated. These soils develop characteristically in well to imperfectly-drained sites, in sandy loam to clay, base-saturated parent materials under forest vegetation in subhumid to humid, mild to very cold climates (Agriculture and Agri-Food Canada 1998). • The CLI has not rated the soils in the vicinity of the proposed Black Pines Pump Station. • No contaminated sites have been recorded at the proposed Black Pines Pump Station within the Soil LSA according to the Federal Contaminated Sites and Solid Waste Landfills Inventory (Treasury Board of Canada Secretariat 2011).
Water Quality and Quantity	• The proposed Black Pines Pump Station, access road and power line are located in the Lower North Thompson River Watershed of the Fraser River Basin. • The proposed power line associated with the pump station crosses the North Thompson River, and Otter and Voght creeks. • No work at the proposed pump station or access road will occur within 30 m of any waterbodies. • The terrain at the proposed Black Pines Pump Station is generally level. Groundwater flow likely follows topography towards east/southeast towards the North Thompson River. • The surficial geology beneath the site is mapped as predominantly fluvial (Young 1983). • No water supply wells are mapped within the proposed site boundary or surrounding Water Quality and Quantity LSA (BC MOE 2013a). • Groundwater levels in the area are expected to be deep based on water well records identified south of the station. • The proposed Black Pines Pump Station overlies Aquifer #283, defined as a moderately vulnerable, sand and gravel deposit (BC MOE 2013a).
Air Emissions	• There is currently no activity causing VOC emissions at the proposed Black Pines Pump Station. • Air quality around the area of the Black Pines Pump Station is expected to be generally very good with some influence from vehicle traffic emissions along Westsyde.
Greenhouse Gas Emissions	• There is currently no activity causing GHG emissions at the proposed Black Pines Pump Station.

TABLE 6.1-11 Cont'd

Environmental Elements	Summary of Considerations
Acoustic Environment	• The ambient acoustical environment in the area of the proposed Black Pines Pump Station is rural and there are no anticipated sources of sound other than those with respect to the sound of nature and traffic along Westsyde Road. • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 600 m to the south of the fenceline of the Black Pines Pump Station. • ASL is based on population density and proximity to road or rail lines and is expected to range between 35-40 dBA at night and 45-50 dBA during the day based on BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009).
Fish and Fish Habitat	• The proposed Black Pines Pump Station and associated power line is located in the Lower North Thompson River Watershed of the Fraser River Basin. • The proposed power line associated with the pump station crosses eight potential watercourses, including the North Thompson River, and Otter and Voght creeks. Of the seven potential watercourse crossings assessed during the fisheries field program, only the North Thompson River was determined to be fish-bearing. Ongoing studies will be conducted at one potential watercourse crossing (Section 5.4 of the Fisheries [British Columbia] Technical Report of Volume 5C). • Of the five indicator species in BC, four (bull trout/Dolly Varden, Chinook salmon, coho salmon and rainbow trout/steelhead) are found in the Lower North Thompson River Watershed (Table 5.7-2 of Section 5.7). No indicators were captured during the assessment at the proposed power line crossing location; however, these four indicators have all been previously recorded in the North Thompson River. • Bull trout and mountain sucker may be found in the Lower North Thompson River Watershed and are both listed as a Species of Special Concern under COSEWIC (2013) and are Blue-listed in BC (BC CDC 2013) (see Table 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C). • Interior Fraser River coho salmon are Endangered under COSEWIC (2013) and may be found in the Lower North Thompson River Watershed (Table 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C).
Wetland Loss or Alteration	• The proposed Black Pines Pump Station and associated power line are located within the Thompson-Okanagan Plateau Ecoregion, a component of the Montane Cordillera Ecozone of Canada. Many of the wetlands within this region have been disturbed by urbanization and agriculture (Ecological Stratification Working Group 1995). • The proposed Black Pines Pump Station and associated power line are also located within the Intermountain Prairie Wetland Region. Wetlands characteristic of this region include marshes bordering fresh to saline ephemeral or semi-permanent shallow waters (Government of Canada 1986). • The proposed Black Pines Pump Station and associated power line are located within the PP BGC Zone of BC. Wetlands are not common in this BGC Zone but typical wetlands include marshes fringing alkaline ponds (BC MOF 1998b, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the proposed Black Pines Pump Station or associated power line during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the proposed Black Pines Pump Station or associated power line. • The proposed Black Pines Pump Station and associated power line are located within a DUC Level 3 Priority Area, Eastern Boreal Forest (DUC 2013).
Vegetation	• The proposed Black Pines Pump Station and associated power line are located within the Thompson-Okanagan Plateau Ecoregion, a component of the Montane Cordillera Ecozone of Canada. This ecoregion is characterized by Engelmann spruce, subalpine fir, lodgepole pine, ponderosa pine, white spruce, Douglas-fir and trembling aspen. Shrub and grass communities dominate open areas and forest understories (Ecological Stratification Working Group 1995). • The proposed Black Pines Pump Station and associated power line are located within the PP BGC Zone of BC. The PP BGC Zone is dominated by ponderosa pine, with Douglas-fir, trembling aspen and black cottonwood occurring less frequently. Understory communities are dominated by grass species, with grasslands periodically scattered throughout the zone (BC MOF 1998b, Meidinger and Pojar 1991). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the proposed Black Pines Pump Station and associated power line. • Records of rare plant observations within 5 km of the proposed Black Pines Pump Station and associated power line were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • A ground-based vegetation survey of both the proposed Black Pines Pump Station and associated power line were conducted on July 26, 2013. Dominant communities observed during the 2013 vegetation survey of the proposed Black Pines Pump Station consist of a mixedwood forest and a tame pasture. Mixedwood forest communities were observed along the associated power line. One rare plant species, riverbank anemone (*Anemone virginiana* var. *cylindroidea*), was observed during the 2013 vegetation survey within the proposed Black Pines Pump Station. It is ranked S3 provincially. No rare plant species were observed along the proposed power line. Further details are provided in Section 4.4 of the Vegetation Technical Report of Volume 5C.

TABLE 6.1-11 Cont'd

Environmental Elements	Summary of Considerations
Vegetation (cont'd)	• No rare ecological communities were observed at the proposed Black Pines Pump Station or along the associated power line. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications. • During the 2013 vegetation survey, one Provincially Noxious weed species (common burdock) was observed and one Regionally Noxious weed species (night-flowering catchfly) was observed.
Wildlife and Wildlife Habitat	• The proposed Black Pines Pump Station and the associated power line lie within the Kamloops LRMP region (BC MFLNRO 2008a). • The Black Pines Pump Station is a new pump station. Dominant communities consist of a mixedwood forest and a seeded pasture. Clearing will be required for the power line within mixedwood forest. • The proposed Black Pines Pump Station and the associated power line are not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), or Wildlife Habitat Areas (BC MOE 2005b). • The proposed Black Pines Pump Station and the associated power line are located in a DUC Level 3 Priority Area, Eastern Boreal Forest (DUC 2013). • The proposed power line crosses the North Thompson River. • The proposed Black Pines Pump Station is located in the WMU 3-28 (BC ILMB 2006). • The proposed power line is located in WMUs 3-27 and 3-28 (BC ILMB 2006). • A ground-based wildlife habitat reconnaissance for the proposed Black Pines Pump Station and the associated power line was conducted on August 13, 2013. The habitat reconnaissance did not identify any features of concern on the Black Pines Pump Station site. Refer to the Wildlife Technical Report of Volume 5C for further details. The habitat reconnaissance for the power line was limited by land access and will be surveyed in 2014 (see Section 9.0). • A supplemental wildlife survey will be conducted for both the Black Pines Pump Station and associated power line (see Section 9.0). • A participant from Tk'emlups Te Secwepemc (Kamloops) accompanied the aquatics crews on field studies along the proposed Black Pines power line from April 8 to 12, 2013. The participant identified cottonwood trees along the proposed power line corridor and reported that this land was excellent deer habitat. No site-specific concerns were identified by the participant during the study.
Species at Risk or Species of Special Status and Related Habitat	• Bull trout and mountain sucker are both considered to be Species of Special Concern under COSEWIC (2013). Interior Fraser River coho salmon are listed as Endangered under COSEWIC (2013). All three species may be found in the Lower North Thompson River Watershed, including the North Thompson River, the only fish-bearing watercourse crossed by the proposed power line. • Records of rare plant observations within 5 km of the proposed Black Pines Pump Station and associated power line were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the proposed Black Pines Pump Station and associated power line (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – Lewis's woodpecker (*SARA*: Threatened, COSEWIC: Threatened, provincial: Red); – American badger (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red); – spotted bat (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); – gopher snake (*deserticola* subspecies) (*SARA*: Threatened, COSEWIC: Threatened, provincial: Blue); – racer (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); – rubber boa (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Yellow); and – western rattlesnake (*SARA*: Threatened, COSEWIC: Threatened, provincial: Blue). • A search of the BC CDC database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of both the proposed Black Pines Pump Station and the associated power line (BC CDC 2012, 2013): – American badger (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red). • A ground-based wildlife habitat reconnaissance for the Black Pines Pump Station and the associated power line was conducted on August 13, 2013. The habitat reconnaissance did not identify any features of concern on the Black Pines Pump Station site. Refer to the Wildlife Technical Report of Volume 5C for further details. The habitat reconnaissance for the power line was limited by land access and will be surveyed in 2014 (see Section 9.0). • Given that new clearing of previously undisturbed lands will be required for the proposed Black Pines Pump Station and the associated power line, both the Black Pines Pump Station and the associated power line have the potential to support suitable habitat for wildlife and plant species at risk. • A supplemental wildlife survey will be conducted for both the Black Pines Pump Station and associated power line (see Section 9.0).

6.1.12 Kamloops Pump Station

The existing Kamloops Pump Station is located at d-094-E/092-I-09 at RK 850.8 within the Kamloops Terminal on lands owned by Trans Mountain in the municipal boundaries of City of Kamloops. Current land use at this site is industrial. No disturbance of previously undisturbed lands is proposed at the Kamloops Pump Station. Three 5,000 HP pump units and one spare 5,000 HP pump unit will be installed at the site. Access to the Kamloops Pump Station is via Highway 5. Table 6.1-12 provides a summary of the environmental elements and considerations for the Kamloops Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Kamloops Pump Station is shown on Figure 6.1-12.

TABLE 6.1-12

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE KAMLOOPS PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Kamloops Pump Station is located within the Interior Plateau Physiographic Region, which is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans, and cones (Demarchi 2011, Holland 1976). • The Kamloops Pump Station is predominantly underlain by igneous and metamorphic rock as well as potential sandstones and carbonates (Monger and McMillan 1989). • The surficial geology beneath the site is mapped as ablation till (Young 1983). • There are no areas of permafrost within the area of Kamloops Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Kamloops Terminal. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Kamloops Terminal. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.1 and 0.2 g (NRCan 2013a). Several minor earthquakes (magnitude 3) and two moderate earthquakes (magnitude 4) have been recorded in the area (NRCan 2013b). • The topography in the area of the Kamloops Pump Station is sloping from the south (high) to the north (low) and the elevation is approximately 740 m above sea level. • Where activities are planned within the Kamloops Pump Station, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing station. NRCan considers unprotected soils in the vicinity of the Kamloops Pump Station to have low wind erosion risk with low climatic sensitivity (NRCan 2010d). • A description of the climate for the BG BGC Zone is provided in Section 5.1.2. • Meteorological data from Environment Canada's Kamloops Airport Station, located approximately 5 km north-northwest of the Kamloops Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of the Kamloops Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Kamloops Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • The CLI has not rated the soils in the vicinity of the Kamloops Pump Station. • Historical spills have been recorded at the Kamloops Pump Station. Soils to be disturbed will be tested prior to construction. If contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• The Kamloops Pump Station is located in the Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain at the Kamloops Pump Station is generally level with a gentle slope to the northeast. Groundwater flow direction is likely toward the east and then northeast to the Thompson River. • The surficial geology beneath the site is mapped as ablation till (Young 1983). • Two water supply wells are defined within the site boundary (ID #18637 and #14817). Well #14817 is owned and operated by Trans Mountain. One other well is located within the surrounding Water Quality and Quantity LSA (BC MOE 2013a). • Groundwater levels in the area are not reported, but are expected to be moderate to deep. • The Kamloops Terminal does not overlie any mapped aquifers (BC MOE 2013a).
Air Emissions	• Continuous VOC, H_2S and mercaptan emissions are primarily due to standing and working losses from existing product storage tanks at the Kamloops Pump Station. • Fugitive emissions from leaks are expected to be a small contributor relative to emissions from existing tanks. • Small amount of continuous CAC emissions are associated with combustion of natural gas in-line heaters. • All existing pumps are electrically driven and are not direct sources of CACs. • CAC and VOC emissions from regular testing of emergency diesel generators and fire water pumps are infrequent. • The largest sources of CAC emissions, except PM, in the Air Quality RSA are non-road engines and vehicle traffic. The largest sources of PM emissions in the area are road dust, mining and rock quarrying. The largest sources of VOC emissions are solvent evaporation, non-road engines and vehicle traffic. • Predicted VOC, H_2S and mercaptan concentrations in the Air Quality RSA due to existing operations at the Kamloops Pump Station and other existing natural and anthropogenic sources are presented in the Air Quality and Greenhouse Gas Technical Report of Volume 5C. Maximum concentrations are expected to be below BC ambient air quality objectives and published odour thresholds.

TABLE 6.1-12 Cont'd

Environmental Elements	Summary of Considerations
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Kamloops Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Products handled and stored in existing tanks contain trace levels of GHGs; small amounts might be released through fugitive or process emissions (*e.g.*, CH_4 and formation CO_2). • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Kamloops Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by field staff and contractors.
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 1 and surrounding arterial roadways, local commercial businesses and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 520 m to the southeast of the fenceline of the Kamloops Pump Station. • ASL in the absence of regulated energy facilities ranges between 38-43 dBA at night and 48-53 dBA during the day based on BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Kamloops Pump Station complies with the BC OGC *Noise Control Best Practices Guideline* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Kamloops Pump Station is located in the Thompson River Watershed of the Fraser River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Kamloops Pump Station is located within the Thompson-Okanagan Plateau Ecoregion, a component of the Montane Cordillera Ecozone of Canada. Many of the wetlands with this region have been disturbed by urbanization and agriculture (Ecological Stratification Working Group 1995). • The Kamloops Pump Station is also located within the Intermountain Prairie Wetland Region. Wetlands characteristic of this region include marshes bordering fresh to saline ephemeral or semi-permanent shallow waters (Government of Canada 1986). • The Kamloops Pump Station is located within the Bunchgrass (BG) BGC Zone of BC. Wetlands are common in this BGC Zone and include marshes and saline meadows in shallow basins and associated with ponds and lakes (BC MOF 1998c, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Kamloops Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Kamloops Pump Station. • The Kamloops Pump Station is located on the northern edge of the Douglas Lake Plateau IBA (Bird Studies Canada and Nature Canada 2012). • The Kamloops Pump Station is located within a DUC Level 3 Priority Area, Eastern Boreal Forest (DUC 2013).
Vegetation	• The Kamloops Pump Station is located within the Thompson-Okanagan Plateau Ecoregion, a component of the Montane Cordillera of Canada. This ecoregion is characterized by Engelmann spruce, subalpine fir, lodgepole pine, ponderosa pine, white spruce, Douglas-fir and trembling aspen. Shrub and grass communities dominate open areas and forest understories (Ecological Stratification Working Group 1995). • The Kamloops Pump Station is located within the BG BGC Zone of BC. The BG BGC Zone is dominated by bunchgrasses, with shrubs occurring throughout the range. Ponderosa pine and Douglas-fir grow on steep rocky slopes that occur infrequently, while trembling aspen can occur on wetter areas at higher elevations (BC MOF 1998c, Meidinger and Pojar 1991). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Kamloops Pump Station. • Records of rare plant observations within 5 km of the Kamloops Pump Station were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.

TABLE 6.1-12 Cont'd

Environmental Elements	Summary of Considerations
Wildlife and Wildlife Habitat	• The Kamloops Pump Station lies within the Kamloops LRMP region (BC MFLNRO 2008a). • The Kamloops Pump Station is located adjacent to existing pigging facilities on industrial lands. • The Kamloops Pump Station is not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Kamloops Pump Station is located on the northern edge of the Douglas Lake Plateau IBA (Bird Studies Canada and Nature Canada 2012). • The Kamloops Pump Station is located in a DUC Level 3 Priority Area, Eastern Boreal Forest (DUC 2013). • The Kamloops Pump Station is located in WMU 3-19 (BC ILMB 2006).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Kamloops Pump Station were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Kamloops Pump Station (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – common nighthawk (*SARA*: Threatened, COSEWIC: Threatened, provincial: Yellow); – flammulated owl (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); – Lewis's woodpecker (*SARA*: Threatened, COSEWIC: Threatened, provincial: Red); – sharp-tailed grouse (*columbianus* subspecies) (*SARA*: no status, COSEWIC: no status, provincial: Blue); – western screech-owl (*macfalanei* subspecies) (*SARA*: Endangered, COSEWIC: Threatened, provincial: Red); – American badger (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red); – fringed myotis (provincial: Blue); – gopher snake (*deserticola* subspecies) (*SARA*: Threatened, COSEWIC: Threatened, provincial: Blue); and – rubber boa (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Yellow). • A search of the BC CDC database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Kamloops Pump Station (BC CDC 2012, 2013): – American badger (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red). • Given that the Kamloops Pump Station is an existing facility and all work will be conducted on previously disturbed industrial lands, the Kamloops Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.13 Kingsvale Pump Station

The existing Kingsvale Pump Station is located at b-023-L/092-H-15 at RK 956 on land owned by Trans Mountain. Current land use at this site is industrial. Some forested lands will be disturbed within the existing boundary of the Kingsvale Pump Station. Two 5,000 HP pump units will be installed at the site. A new 138 kV power line approximately 23.5 km long in a 50 m wide right-of-way will also be installed at the site. Access to the Kingsvale Pump Station is via Highway 5. Table 6.1-13 provides a summary of the environmental elements and considerations for the Kingsvale Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Kingsvale Pump Station and proposed power line are shown on Figure 6.1-13.

TABLE 6.1-13

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE KINGSVALE PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Kingsvale Pump Station and associated power line are located within the Interior Plateau Physiographic Region, which is characterized by gentle to moderately sloping rolling uplands with rounded ridges and summits, valleys deeply dissecting the plateau, terraces, fluvial plains, fans, and cones (Demarchi 2011, Holland 1976). • The Kingsvale Pump Station is predominantly underlain by igneous and metamorphic rock as well as potential sandstones and carbonates (Monger and McMillan 1989). • The surficial geology beneath the site is mapped as glacial till (BGC Engineering Inc. 2013a). • There are no areas of permafrost within the area of the Kingsvale Pump Station or associated power line (refer to Section 5.1.1). • No areas of potential terrain instability are known or anticipated to occur in the vicinity of the Kingsvale Pump Station or associated power line. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Kingsvale Pump Station or associated power line. • The site is located in a zone of moderate seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.2 and 0.3 g (NRCan 2013a). Several minor earthquakes (magnitude 3) and one moderate earthquake (magnitude 4) have been recorded near the pump station and associated power line (NRCan 2013b). • The topography in the area of Kingsvale Pump Station is sloping from east (high) to west (low) and the elevation is approximately 900 m above sea level. • The Kingsvale power line crosses predominantly forested lands of rolling terrain of gentle to moderate slopes. • Activities are planned at the Kingsvale Pump Station on forested lands within the boundaries of the existing station. Wind erosion risk for unprotected soils in the vicinity of Kingsvale Pump Station and associated power line is considered negligible and is unrated by NRCan (NRCan 2010d). • A description of the climate for the IDF BGC Zone is provided in Section 5.1.2. • Meteorological data from Environment Canada's Hope Airport Station, located approximately 75 km southwest of the Kingsvale Pump Station, are provided in Section 5.1.2. • No major tornadoes or hailstorms have been recorded in the vicinity of the Kingsvale Pump Station or associated power line (NRCan 2010b,c).
Soil and Soil Productivity	• Some forested lands will be disturbed within the existing boundary of the Kingsvale Pump Station. • Soils in the vicinity of the Kingsvale Pump Station and associated power line are dominated by Humo-Ferric Podzol soils (Valentine *et al.* 1978). Podzolic soils have B horizons in which the dominant accumulated product is amorphous material composed mainly of humified organic matter (Agriculture and Agri-Food Canada 1998). • The CLI (1976) has rated the soils in the vicinity of the Kingsvale Pump Station and associated power line as having severe limitations (Class 6) to crop production. Soils in this class are capable of only producing perennial forage crops and improvement practices are not feasible. • No contamination is anticipated at the Kingsvale Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented.
Water Quality and Quantity	• The Kingsvale Pump Station and associated power line is located in the Lower Nicola River Watershed of the Fraser River Basin. • No work at the Kingsvale Pump Station will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity for the pump station is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • The proposed power line route crosses Kanevale, Kimble, Howarth and Nisson creeks. • The terrain slopes down to the west across the site. Site drainage and groundwater flow is expected to be towards the Coldwater River located approximately 500 m west of the site. • The surficial geology beneath the site is mapped as glacial till (BGC Engineering Inc. 2013a). • No water supply wells are located on the site and approximately 10 water wells are located within the Water Quality and Quantity LSA. • Groundwater levels in the area appear variable with reported water levels from driller's records ranging from 4-60 m bgl. • The Kingsvale Pump Station and associated power line do not overlie any mapped aquifers (BC MOE 2013a).
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Kingsvale Pump Station are estimated to be 2.2 tonnes per year. • Air quality around the area of the Kingsvale Pump Station is expected to be primarily influenced by vehicle traffic emissions along Highway 5 and a nearby compressor station.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Kingsvale Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Kingsvale Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by field staff and contractors.

TABLE 6.1-13 Cont'd

Environmental Elements	Summary of Considerations
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 5, surrounding arterial roadways and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 300 m to the southwest of the fenceline of the Kingsvale Pump Station. • ASL in the absence of regulated energy facilities is approximately 35 dBA at night and 45 dBA during the day based on BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Kingsvale Pump Station complies with the BC OGC *Noise Control Best Practices Guideline* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The power line associated with the Kingsvale Pump Station is located within the Lower Nicola and Similkameen river watersheds of the Fraser River Basin. The pump station is located in the Lower Nicola River Watershed. • The power line associated with the Kingsvale Pump Station crosses 28 potential watercourses, including Kanevale, Kimble, Howarth and Nisson creeks. • Of the 26 potential watercourses assessed during the fisheries field program, two (*i.e.,* Kanevale and Howarth creeks) were determined to be fish-bearing. Ongoing studies will be conducted at two potential watercourse crossings (Section 5.5 of the Fisheries [British Columbia] Technical Report of Volume 5C). • Of the five indicator species in BC, four (bull trout/Dolly Varden, Chinook salmon, coho salmon and rainbow trout/steelhead) are found in the Lower Nicola and Similkameen river watersheds) and may be found in watercourses crossed by the proposed power line. Rainbow trout/steelhead was captured or observed during the assessment at Howarth Creek, and rainbow trout/steelhead has been previously reported at both Howarth and Kanevale creeks. Bull trout is considered a Species of Special Concern under COSEWIC (2013) and is Blue-listed in BC (BC CDC 2013). Chiselmouth is also Blue-listed in BC (BC CDC 2013). Both species may be found in the Lower Nicola and Similkameen river watersheds (Table 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C).
Wetland Loss or Alteration	• The Kingsvale Pump Station and associated power line are located within the Thompson-Okanagan Plateau Ecoregion, a component of the Montane Cordillera Ecozone of Canada (Ecological Stratification Working Group 1995). • The Kingsvale Pump Station and associated power lines are also located within the Intermountain Prairie Wetland Region. Wetlands characteristic of this region include marshes bordering fresh to saline ephemeral or semi-permanent shallow waters (Government of Canada 1986). • The Kingsvale Pump Station and associated power line are located within the IDF BGC Zone of BC. In this BGC Zone, wetlands are often found in depressions, around open water, small streams and drainage channels. Wetland types include fens, marshes as well as shrubby swamps (BC MOF 1996b, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • It was determined during satellite imagery interpretation that the proposed power line encounters 23 potential wetlands. Ground-based wetland surveys will be conducted along the proposed power line in summer 2014 (see Section 9.0). • No wetlands were identified within or adjacent to the Kingsvale Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required for the station. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013), Migratory Bird Sanctuaries (Environment Canada 2013b) or DUC Priority Areas (DUC 2013) located within the Wetland LSA surrounding the Kingsvale Pump Station and associated power line.

TABLE 6.1-13 Cont'd

Environmental Elements	Summary of Considerations
Vegetation	• The Kingsvale Pump Station and associated power line are located within the Thompson-Okanagan Plateau Ecoregion, a component of the Montane Cordillera Ecozone of Canada. This ecoregion is characterized by Engelmann spruce, subalpine fir, lodgepole pine, ponderosa pine, white spruce, Douglas-fir and trembling aspen. Shrub and grass communities dominate open areas and forest understories (Ecological Stratification Working Group 1995). • The Kingsvale Pump Station and associated power line are located within the IDF BGC Zone of BC. The IDF BGC Zone is dominated by closed, mature forests of Douglas-fir. Mixed stands of Douglas-fir, lodgepole pine, ponderosa pine, white spruce, western redcedar and trembling aspen are also common. Grassland communities also occur in parts of the zone (Meidinger and Pojar 1991). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Kingsvale Pump Station or the associated power line. • Records of rare plant observations within 5 km of the Kingsvale Pump Station and associated power line were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • A ground-based vegetation survey of the Kingsvale Pump Station was conducted on July 22, 2013. Dominant communities observed during the 2013 vegetation survey at the Kingsvale Pump Station and associated power line consist of an upland conifer forest and a seeded area dominated by agronomic grasses. No rare plants or rare ecological communities were observed during the 2013 vegetation survey of the Kingsvale Pump Station. The associated power line is assumed to be on native vegetation based upon a review of satellite imagery, the professional judgement of the vegetation team and the adjacent land conditions. Mitigation contained in the Facilities EPP of Volume 6C is considered adequate for expected conditions and a supplemental vegetation survey conducted prior to construction will confirm the predictions of potential effects on the native vegetation in this area. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications. • During the 2013 vegetation survey, two Provincially Noxious weed species, Dalmatian toadflax and perennial sow-thistle, were observed. One Regionally Noxious weed species, ox-eye daisy, was observed.
Wildlife and Wildlife Habitat	• The Kingsvale Pump Station and the associated power line do not lie within an LRMP region (BC MFLNRO 2008a). • The Kingsvale Pump Station is located on industrial and forested lands. Clearing of forested lands will be required for the Kingsvale Pump Station and the associated power line. Dominant communities consist of an upland conifer forest and a seeded area dominated by agronomic grasses. • The Kingsvale Pump Station and the associated power line are not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013) or designated caribou range (BC MOE 2008). • The Kingsvale Pump Station is adjacent (north, east and south sides) to ungulate winter range (u-3-003) for mule deer (BC MOE 2005a). • The power line crosses ungulate winter range (u-3-003) for mule deer in four different locations for a total of approximately 6.2 km (BC MOE 2005a). • The power line crosses a wildlife habitat area (WHA 3-143) for Williamson's sapsucker for approximately 1 km (BC MOE 2005b). The proposed power line is also located approximately 0.1 km, 0.9 km and 1.3 km from three other Williamson's sapsucker wildlife habitat areas (WHAs 3-142, 3-095 and 3-130 respectively) (BC MOE 2005b). • The Kingsvale Pump Station and the associated power line are not located in a DUC Priority Area (DUC 2013). • The Kingsvale Pump Station is located in WMU 3-13 (BC ILMB 2006). The power line crosses WMU 3-13, WMU 8-5 and WMU 8-6 (BC ILMB 2006). • A ground-based wildlife habitat reconnaissance for the Kingsvale Pump Station and the associated power line was conducted on August 17, 2013. The habitat reconnaissance did not identify any features of concern (see the Wildlife Technical Report of Volume 5C for further details). The habitat reconnaissance was limited by land access. • A supplemental wildlife survey will be conducted for both the Kingsvale Pump Station and associated power line (see Section 9.0).

TABLE 6.1-13 Cont'd

Environmental Elements	Summary of Considerations
Species at Risk or Species of Special Status and Related Habitat	• Bull trout is considered a species of Special Concern under COSEWIC (2013) and may be found in the Lower Nicola and Similkameen river watersheds (Table 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C). • Records of rare plant observations within 5 km of the Kingsvale Pump Station and the associated power line were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Kingsvale Pump Station and associated power line (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – common nighthawk (*SARA*: Threatened, COSEWIC: Threatened, provincial: Yellow); – Williamson's sapsucker (*SARA*: Endangered, COSEWIC: Endangered, provincial: Blue); – American badger (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red); – fringed myotis (provincial: Blue); – gopher snake (*deserticola* subspecies) (*SARA*: Threatened, COSEWIC: Threatened, provincial: Blue); – rubber boa (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Yellow); and – western toad (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue). • A search of the BC CDC database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Kingsvale Pump Station or the associated power line (BC CDC 2012, 2013). • A ground-based wildlife habitat reconnaissance for the Kingsvale Pump Station and the associated power line was conducted on August 17, 2013. The habitat reconnaissance did not identify any features of concern (see the Wildlife Technical Report of Volume 5C for further details). The habitat reconnaissance was limited by land access. • A supplemental wildlife survey will be conducted for both the Kingsvale Pump Station and associated power line (see Section 9.0). • Given that new clearing of previously undisturbed lands will be required for the Kingsvale Pump Station and the associated power line, both the Kingsvale Pump Station and the associated power line have the potential to have suitable habitat for wildlife and plant species at risk.

6.1.14 Sumas Pump Station

The existing Sumas Pump Station is located at c-073-B/092-G-01 at RK 1114.2 on lands owned by Trans Mountain in the municipal boundary of the City of Abbotsford. Current land use at this facility site is industrial. All work will be conducted within the existing disturbed fenced area. No disturbance of previously undisturbed lands is proposed at the Sumas Pump Station. One new 2,500 HP pump unit will be installed at the site serving the Puget Sound line. Access to the Sumas Pump Station is via Highway 1. Table 6.1-14 provides a summary of the environmental elements and considerations for the Sumas Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Sumas Pump Station is shown on Figure 6.1-14.

TABLE 6.1-14

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE SUMAS PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Sumas Pump Station is located within the Cascade Mountains Physiographic Region, which is characterized by rugged mountain ranges, steeply incised tributary valleys, wide U-shaped main valleys, relict glacial landforms, terraces, fans, cones, steep slopes, fluvial plains and small basins (Demarchi 2011, Holland 1976). • The Sumas Pump Station may be underlain by a variety of rock types of volcanic or sedimentary origin in addition to metamorphic rocks such as gneiss and schist (BGC Engineering Inc. 2013c). • The surficial geology beneath the site is mapped as lacustrine deposits consisting of silt, clayey silt and silty clay up to 15 m thick but normally less than 3 m thick overlying sand (Armstrong 1961). • There are no areas of permafrost within the area of the Sumas Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Sumas Pump Station. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Sumas Pump Station. • The site is located in a zone of high seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.4 and 0.5 g (NRCan 2013a). Several known and suspected post-glacial faults lie near the pump station. Major earthquakes (up to and over magnitude 7) have occurred in the Coast Mountains and Cascade Ranges around the pump station (NRCan 2013b). Refer to the Seismic Assessment Desktop Study of Volume 4A for additional information. • There is a large earthen dike surrounding the Sumas Pump Station as protection against flooding of the Fraser River. The topography within the dike is flat and the elevation is approximately 9 m above sea level. • Where activities are planned within the Sumas Pump Station, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing station. NRCan considers unprotected soils in the vicinity of the Sumas Pump Station to have moderate wind erosion risk with low climatic sensitivity (NRCan 2010d). • A description of the climate for the Coastal Western Hemlock (CWH) BGC Zone is provided in Section 5.1.3. • Meteorological data from Environment Canada's Chilliwack Station, located approximately 20 km northeast of the Sumas Pump Station, are provided in Section 5.1.4. • No major tornadoes or hailstorms have been recorded in the vicinity of the Sumas Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Sumas Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • The CLI has not rated the soils in the vicinity of the Sumas Pump Station. • Historical spills have been recorded at the Sumas Pump Station. Soils to be disturbed will be tested prior to construction. If contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• The Sumas Pump Station is located in the Chilliwack River Watershed of the Fraser River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • The terrain at the Sumas Pump Station is level and considered relatively stable. A high water table is noted in the area. • The surficial geology beneath the site is mapped as lacustrine deposits consisting of silt, clayey silt and silty clay up to 15 m thick but normally less than 3 m thick overlying sand (Armstrong 1961). • One water supply well is located on the site (ID # 15012), but its current use is unknown. One other well is located within the Water Quality and Quantity LSA. • The Sumas Pump Station overlies the Sumas Prairie Aquifer, Aquifer #21, a moderately vulnerable aquifer (BC MOE 2013a).
Air Emissions	• All existing pumps are electrically driven and are not direct sources of CACs. • Fugitive VOC emissions from leaks at the Sumas Pump Station are estimated to be 7.8 tonnes per year. • Air quality around the area of the Sumas Pump Station is described as part of the Project settings for the Sumas Terminal Air Quality RSA (see Table 6.1-15).
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Sumas Pump Station are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Sumas Pump Station. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by field staff and contractors.

TABLE 6.1-14 Cont'd

Environmental Elements	Summary of Considerations
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along Highway 1, agricultural activities and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 110 m to the southwest of the fenceline of the Sumas Pump Station. • ASL in the absence of regulated energy facilities ranges between 35-45 dBA at night and 45-55 dBA during the day based on BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). • A measurement program was conducted at both the facility and representative ambient sound level at receptors surrounding the facility. The results of the receptor-based program gave a range of values between 52-54 dBA during the nighttime and 54-55 dBA during daytime. • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions observed and measurements of the major on-site sources of sound. Specifications of equipment not operating during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Sumas Pump Station complies with the BC OGC *Noise Control Best Practices Guideline* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Sumas Pump Station is located in the Chilliwack River Watershed of the Fraser River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Sumas Pump Station is located within the Lower Mainland Ecoregion, a component of the Pacific Maritime Ecozone of Canada. Wetter areas are characterized by Douglas-fir, western hemlock and western redcedar. Coastal salt marshes are located on the Fraser River delta and along Boundary Bay (Ecological Stratification Working Group 1995). • The Sumas Pump Station is also located within the Intermountain Prairie Wetland Region. Wetlands characteristic of this region include marshes bordering fresh to saline ephemeral or semi-permanent shallow waters (Government of Canada 1986). • The Sumas Pump Station is located within the CWH BGC Zone of BC. In this BGC Zone, wetlands are often found in depressions, around open water, small streams and drainage channels. Wetlands types include fens, marshes as well as shrubby swamps (BC MOF 1999, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Sumas Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Sumas Pump Station. • The Sumas Pump Station is located in a DUC Level 2 Priority Area, the BC Coastal Areas and Estuaries (DUC 2013).
Vegetation	• The Sumas Pump Station is located within the Lower Mainland Ecoregion, a component of the Pacific Maritime Ecozone of Canada. This ecoregion is characterized by forests of Douglas-fir, western hemlock and western redcedar. Understories of shrubs, vines and moss are common in mature forests. Arbutus and dogwood communities are common on drier sites (Ecological Stratification Working Group 1995). • The Sumas Pump Station is located within the CWH BGC Zone of BC which is dominated by western hemlock, with western redcedar and Douglas-fir frequent throughout the zone. Amabilis fir, yellow-cedar, shore pine, grand fir, western white pine, bigleaf maple and black cottonwood are also common (Meidinger and Pojar 1991). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Sumas Pump Station. • Records of rare plant observations within 5 km of the Sumas Pump Station were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Sumas Pump Station is not in an LRMP region (BC MFLNRO 2008a). • The Sumas Pump Station is located on industrial lands. • The Sumas Pump Station is not located within or adjacent to any parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Sumas Pump Station is located in a DUC Level 2 Priority Area, the BC Coastal Areas and Estuaries (DUC 2013). • The Sumas Pump Station is located in WMU 2-4 (BC ILMB 2006).

TABLE 6.1-14 Cont'd

Environmental Elements	Summary of Considerations
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Sumas Pump Station were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Sumas Pump Station (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – California gull (provincial: Blue); – horned lark (*strigata* subspecies) (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red); – short-eared owl (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: S3B, S2N, Blue, Priority 2); – mountain beaver (*rufa* subspecies) (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); and – Oregon forestsnail (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red). • A search of the BC CDC database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Sumas Pump Station (BC CDC 2012, 2013): – mountain beaver (*rufa* subspecies) (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); and – Oregon forestsnail (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red). • Given that the Sumas Pump Station is an existing facility and all work will occur within the existing fenced area on previously disturbed land, the Sumas Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.1.15 Sumas Terminal

The existing Sumas Terminal is located at a-097-B/092-G-01 at RK 1117.5 on lands owned by Trans Mountain in the municipal boundaries of the City of Abbotsford. Current land use at this facility site is industrial and undisturbed forested lands. The proposed activities are within the existing Sumas Terminal property boundary, however, the existing fenceline will be moved approximately 20 m north (0.7 ha of new disturbance). One new 27,820 m^3 (175,000 bbl) storage tank will be installed at the Sumas Terminal. Access to the Sumas Terminal is via Highway 1. Table 6.1-15 provides a summary of the environmental elements and considerations for the Sumas Terminal pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Sumas Terminal is shown on Figure 6.1-15.

TABLE 6.1-15

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE SUMAS TERMINAL

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Sumas Terminal is located within the Georgia Depression Physiographic Region, which is characterized by a flat valley floor 1-5 km wide, steep valley walls, gently rolling uplands and ridges, gently rolling to flat lowlands of terraces and plains, and deltas (Armstrong 1984, Holland 1976). • The Sumas Terminal is likely underlain by coarse-grained clastic and volcanic rock types (BGC Engineering Inc. 2013c). • The surficial geology beneath the site is mapped as bedrock within 7.6 m of surface covered by drift (likely Sumas till) (Armstrong 1961). • There are no areas of permafrost within the area of the Sumas Terminal (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Sumas Terminal. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Sumas Terminal. • The site is located in a zone of high seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.4 g and 0.5 g (NRCan 2013a). Several known and suspected post-glacial faults lie near the pump station. Major earthquakes (up to and over magnitude 7) have occurred in the Coast Mountains and Cascade Ranges around the pump station (NRCan 2013b). Refer to the Seismic Assessment Desktop Study of Volume 4A for additional information. • The topography in the area of the Sumas Terminal is sloping from north (high) to south (low) and the elevation is approximately 200 m above sea level. • Where activities are planned within the Sumas Terminal, construction of the new infrastructure will be conducted within the boundaries of the existing station, however, the existing fenceline will be moved approximately 20 m north in forested lands to accommodate a new access road and earthworks associated with the new storage tank. NRCan considers unprotected soils in the vicinity of the Sumas Terminal to have moderate wind erosion risk with low climatic sensitivity (NRCan 2010d). • A description of the climate for the CWH BGC Zone is provided in Section 5.1.3. • The following meteorological data were obtained from an Environment Canada meteorological station (1100030) at Abbotsford Airport (Environment Canada 2013a). The data were taken approximately 15 km southwest of the Sumas Terminal. – Average monthly rainfall for Abbotsford Airport is 123.6 mm and the average monthly rainfall from November to March is 174.9 mm. In November of 1971, Abbotsford Airport recorded its highest daily rainfall of 95 mm, which is well below the monthly average of 241.5 mm for the month of November. – Average monthly snowfall for Abbotsford Airport is 4.6 cm and the average monthly snowfall from November to March is 10.9 cm. In January of 1954, Abbotsford Airport recorded its highest daily snowfall of 49.8 cm, well above the 18.5 cm average for the month of January. – Average daily temperature for Abbotsford Airport is 10.4°C, with the warmest month in August averaging 18.2°C and coolest month in December, averaging 2.9°C. In July of 2009, Abbotsford Airport experienced its warmest day of 38°C and in January of 1950, its coolest day at -21.1°C. • No major tornadoes or hailstorms have been recorded in the vicinity of the Sumas Terminal (NRCan 2010b,c).
Soil and Soil Productivity	• Current land use at the Sumas Terminal is industrial and undisturbed forested lands. The proposed activities are within the existing Sumas Terminal property boundary, however, the existing fenceline will be moved approximately 20 m north. The Sumas Terminal has been previously disturbed and contains tanks, buildings and other equipment. • The CLI has not rated the soils in the vicinity of the Sumas Terminal. • Historical spills have occurred at the Sumas Terminal and soils to be disturbed will be tested prior to construction. If contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• The Sumas Terminal is located in the Chilliwack River Watershed of the Fraser River Basin. • No work will occur within 30 m of any watercourse, however, there is a potential shrubby swamp associated with an ephemeral drainage outside of the Sumas Terminal boundary that will be confirmed during supplemental surveys in 2013. • Hydrostatic testing is planned for the piping and new tank to be installed within the Sumas Terminal. Water may be withdrawn and released from Trans Mountain's existing fire water pond at the Sumas Terminal. Alternatively, test water may be diverted from a nearby river or creek, subject to obtaining a water withdrawal permit, or purchased from municipalities depending on availability from natural sources. Following testing, water will be tested for contaminants before being treated and either discharged back into the fire water pond, trucked away, or released to a natural waterbody or the municipal sewer system. • The terrain at the Sumas Terminal is sloped. Groundwater flow direction is inferred to be to the southeast (SNC Lavalin Inc. 2013). • The surficial geology beneath the site is mapped as bedrock within 7.6 m of the surface covered by drift (likely Sumas till) (Armstrong 1961). The site is located over a topographic divide with drainage flowing to the south-southwest on the southern half of the site and to the northeast on the northern half of the site. • Three water supply wells are located within the site boundaries (ID # 6686, #67529 and #75552), though their uses have not been confirmed. • Nine wells are located within the Water Quality and Quantity LSA.

TABLE 6.1-15 Cont'd

Environmental Elements	Summary of Considerations
Water Quality and Quantity (cont'd)	• Groundwater levels are expected to be approximately 8-15 m bgl based on local monitoring wells. Depth to groundwater ranged from 1.6-4.2 m bgl. • The Sumas Terminal does not overlie any mapped aquifers (BC MOE 2013a). • Studies conducted by SNC Lavalin Inc. (2013) following the release of 90,000 L of light crude oil from an above ground storage tank indicate that the release was contained within the bermed containment area around the above ground storage tank. Hydrocarbons were detected in three wells at less than guideline concentrations. In addition, aluminum and cadmium were detected at concentrations exceeding the aquatic life guideline in three and two wells respectively. • Groundwater samples collected from five perimeter monitoring wells by Golder Associates (2013) showed analytical results to be all less than the reporting limit suggesting no off-site migration of hydrocarbons.
Air Emissions	• Continuous VOC, H_2S and mercaptan emissions are primarily due to standing and working losses from existing product storage tanks at the Sumas Terminal. • Fugitive emissions from leaks are expected to be a small contributor relative to emissions from existing tanks. • All existing pumps are electrically driven and are not direct sources of CACs. • CAC and VOC emissions from regular testing of emergency diesel generators and fire water pumps are infrequent. • The largest sources of CAC emissions, except PM, in the Air Quality RSA are on-road motor vehicle traffic, non-road engines and aircraft. The largest sources of PM emissions in the area are road dust, and agricultural and construction activities. The largest sources of VOC emissions are solvent evaporation and natural sources. • Predicted VOC, H_2S and mercaptan concentrations in the Air Quality RSA due to existing operations at the Sumas Terminal and other existing natural and anthropogenic sources are presented in the Air Quality and Greenhouse Gas Technical Report of Volume 5C. Maximum concentrations are expected to be below BC ambient air quality objectives and published odour thresholds.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Sumas Terminal are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Products handled and stored in existing tanks contain trace levels of GHGs; small amounts might be released through fugitive or process emissions (*e.g.*, CH_4 and formation CO_2). • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Sumas Terminal. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are aggregate facilities (borrow pits) located to the south and southeast of the site, local traffic, and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 60 m south of the fenceline of the Sumas Terminal. • ASL in the absence of regulated energy facilities is approximately 35-38 dBA at night and 45-48 dBA during the day based on BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). • A measurement program to define sound emissions from the existing facility was conducted. • A noise model was generated based on existing conditions and measurements of the major sources of sound. Specifications of non-operating equipment during the site visit were used to estimate sound levels. Applicable buildings and shelters were modelled along with their appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Sumas Terminal is expected to comply with the BC OGC *Noise Control Best Practices Guideline* for permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Fish and Fish Habitat	• The Sumas Terminal is located in the Chilliwack River Watershed of the Fraser River Basin. • Hydrostatic testing is planned for the piping and new tank to be installed within the Sumas Terminal. Water may be withdrawn and released from Trans Mountain's existing fire water pond at the Sumas Terminal. Alternatively, test water may be diverted from a nearby river or creek, subject to obtaining a water withdrawal permit, or purchased from municipalities depending on availability from natural sources. • All five BC indicator species (*i.e.,* bull trout/Dolly Varden, Chinook salmon, coho salmon, cutthroat trout and rainbow trout/steelhead) are found in the Chilliwack River Watershed. • White sturgeon (Endangered under *SARA*, Threatened under COSEWIC for the Lower Fraser River population [2013a] and Red-listed [BC CDC 2013]), Salish sucker (Endangered under *SARA*, and provincially Red-listed [BC CDC 2013]), bull trout (Blue-listed [BC CDC 2013] and Special Concern under COSEWIC [2013a]), coho salmon (Endangered under COSEWIC for the interior Fraser River population [COSEWIC 2013a] and sockeye salmon (Endangered under COSEWIC [2013a] for the Cultus Lake population) are known to occur in the Chilliwack River Watershed.
Wetland Loss or Alteration	• The Sumas Terminal is located within the Lower Mainland Ecoregion, a component of the Pacific Maritime Ecozone of Canada. Wetter areas are characterized by Douglas-fir, western hemlock and western redcedar. Coastal salt marshes are located on the Fraser River delta and along Boundary Bay (Ecological Stratification Working Group 1995). • The Sumas Terminal is also located within the Intermountain Prairie Wetland Region. Wetlands characteristic of this region include marshes bordering fresh to saline ephemeral or semi-permanent shallow waters (Government of Canada 1986).

TABLE 6.1-15 Cont'd

Environmental Elements	Summary of Considerations
Wetland Loss or Alteration (cont'd)	• The Sumas Terminal is located within the CWH BGC Zone of BC. In this BGC Zone, wetlands are often found in depressions, around open water, small streams and drainage channels. Wetlands types include fens, marshes as well as shrubby swamps (BC MOF 1999, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within to the Sumas Terminal during the helicopter reconnaissance and satellite imagery review. However, there is a potential shrubby swamp associated with an ephemeral drainage outside of the Sumas Terminal boundary that will need to be confirmed during supplemental surveys in 2013. There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Sumas Terminal. • The Sumas Terminal is located within a DUC Level 2 Priority Area, the BC Coastal Areas and Estuaries (DUC 2013).
Vegetation	• The Sumas Terminal is located within the Lower Mainland Ecoregion, a component of the Pacific Maritime Ecozone of Canada. This ecoregion is characterized by forests of Douglas-fir, western hemlock and western redcedar. Understories of shrubs, vines and moss are common in mature forests. Arbutus and dogwood communities are common on drier sites (Ecological Stratification Working Group 1995). • The Sumas Terminal is located within the CWH BGC Zone of BC. The CWH BGC Zone is dominated by western hemlock, with western redcedar and Douglas-fir frequent throughout the zone. Amabilis fir, yellow-cedar, shore pine, grand fir, western white pine, bigleaf maple and black cottonwood are also common (Meidinger and Pojar 1991). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Sumas Terminal. • Records of rare plant observations within 5 km of the Sumas Terminal were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • The proposed expansion of the Sumas Terminal is assumed to be on native vegetation based upon a review of satellite imagery and the professional judgement of the vegetation team. Mitigation contained in the Facilities EPP of Volume 6C is considered adequate for expected conditions and a supplemental vegetation survey conducted prior to construction will confirm the predictions of potential effects on the native vegetation in this area. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Sumas Terminal is located in the City of Abbotsford in the Fraser Valley Regional District (FVRD). • The expansion will occur onto industrial and undisturbed forested lands and clearing will be required. • The Sumas Terminal is not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Sumas Terminal is located in a DUC Level 2 Priority Area, the BC Coastal Areas and Estuaries (DUC 2013). • The Sumas Terminal is located in WMU 2-4 (BC ILMB 2006). • A supplemental wildlife survey will be conducted in 2014 (see Section 9.0).
Species at Risk or Species of Special Status and Related Habitat	• White sturgeon (Endangered under *SARA* and Threatened under COSEWIC for the Lower Fraser River population [2013a]), Salish sucker (Endangered under *SARA*), bull trout (Special Concern under COSEWIC [2013a]), coho salmon (Endangered under COSEWIC for the interior Fraser River population [COSEWIC 2013a] and sockeye salmon (Endangered under COSEWIC [2013a] for the Cultus Lake population) are known to occur in the Chilliwack River Watershed. • Records of rare plant observations within 5 km of the Sumas Terminal were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • A supplemental wildlife survey will be conducted in 2014 (see Section 9.0). • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Sumas Terminal (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – common nighthawk (*SARA*: Threatened, COSEWIC: Threatened, provincial: Yellow); – mountain beaver (*rufa* subspecies) (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); – olympic shrew (provincial: Red); – Pacific water shrew (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red); – southern red-backed vole (*occidentalis* subspecies) (provincial: Red); – Townsend's big-eared bat (provincial: Blue); – Trowbridge's shrew (provincial: Blue); – rubber boa (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Yellow); – coastal tailed frog (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); and – Oregon forestsnail (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red).

TABLE 6.1-15 Cont'd

Environmental Elements	Summary of Considerations
Species at Risk or Species of Special Status and Related Habitat (cont'd)	• A search of the BC CDC database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Sumas Terminal (BC CDC 2012, 2013): – mountain beaver (*rufa* subspecies) (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); and – Oregon forestsnail (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red). • Given that the Sumas Terminal will require new clearing of previously undisturbed forested lands, the Sumas Terminal has the potential to be suitable habitat for wildlife and plant species at risk. A supplemental survey will be conducted in 2014 to confirm predictions relating to species at risk (see Section 9.0).

6.1.16 Burnaby Terminal

The existing Burnaby Terminal is located at a-025-D/092-G-07 at RK 1179.8 on lands owned by Trans Mountain in the municipal boundaries of the City of Burnaby. Current land use at this facility site is industrial. The proposed activities are within the existing Burnaby Terminal property boundary on previously disturbed industrial lands. Two new 39,750 m^3 (250,000 bbl) storage tanks, 10 new 45,310 m^3 (285,000 bbl) storage tanks and 2 new 53,260 m^3 (335,000 bbl) storage tanks will be installed at the Burnaby Terminal. An existing 12,720 m^3 (80,000 bbl) tank will be dismantled and replaced by one of the 45,310 m^3 (285,000 bbl) tanks. Access to the terminal is via Shellmont Street. Table 6.1-16 provides a summary of the environmental elements and considerations for the Burnaby Terminal pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Burnaby Terminal is shown on Figure 6.1-16.

TABLE 6.1-16

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE BURNABY TERMINAL

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Burnaby Terminal is located within the Georgia Depression Physiographic Region, which is characterized by a flat valley floor 1-5 km wide, steep valley walls, gently rolling uplands and ridges, gently rolling to flat lowlands of terraces and plains, and deltas (Armstrong 1984, Holland 1976). • The Burnaby Terminal is likely underlain by coarse-grained clastic and volcanic rock types (BGC Engineering Inc. 2013c). • The surficial geology beneath the site is mapped as Capilano sediments consisting of beach deposits of poorly-sorted sand to gravel normally less than 1 m thick (may be up to 8 m thick). The extreme northeast corner of the facility is underlain by tertiary bedrock (Armstrong and Hicock 1980). • There are no areas of permafrost within the area of the Burnaby Terminal (refer to Section 5.1.1). • Terrain instability has the potential to occur along ravine slopes located within the terminal site. Otherwise, no areas of potential terrain instability are known to occur in the vicinity of the Burnaby Terminal. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Burnaby Terminal. • The site is located in a zone of high seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.4 and 0.5 g (NRCan 2013a). Several known and suspected post-glacial faults lie near the pump station. Major earthquakes (up to and over magnitude 7) have occurred in the Coast Mountains and Cascade Ranges around the pump station (NRCan 2013b). Refer to the Seismic Assessment Desktop Study of Volume 4A for additional information. • The topography in the area of the Burnaby Terminal is sloping from northeast (high) to the southwest (low) and the elevation is approximately 160 m above sea level. • Where activities are planned within the Burnaby Terminal, soils have predominantly been disturbed for industrial use, and construction of the new infrastructure will be conducted within the boundaries of the existing station. NRCan considers unprotected soils in the vicinity of the Burnaby Terminal to have moderate wind erosion risk with low climatic sensitivity (NRCan 2010d). • A description of the climate for the CWH BGC Zone is provided in Section 5.1.3. • The following meteorological data were obtained from an Environment Canada meteorological station (1108447) at Vancouver International Airport (Environment Canada 2013a). The data were taken approximately 20 km southwest of the Burnaby Terminal. – Average monthly rainfall for Vancouver Airport is 96.1 mm and the average monthly rainfall from November to March is 140.4 mm. In September of 2004, Vancouver Airport recorded its highest daily rainfall of 91.6 mm, which is above the monthly average of 50.9 mm for the month of September. – Average monthly snowfall for Vancouver Airport is 3.2 cm and the average monthly snowfall from November to March is 7.5 cm. In December of 1996, Vancouver Airport recorded its highest daily snowfall of 41 cm, well above the 14.8 cm average for the month of December. – Average daily temperature for Vancouver Airport is 10.4°C, with the warmest month in August, averaging 18°C and coolest month in December, averaging 3.6°C. In July of 2009, Vancouver Airport experienced its warmest day of 34.4°C and in January of 1950, its coolest day at -17.8°C. • No major tornadoes or hailstorms have been recorded in the vicinity of the Burnaby Terminal (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Burnaby Terminal will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • Historical spills have been recorded at the Burnaby Terminal. Soils in the area of the storage yard located in the terminal will be tested prior to construction. If contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• The Burnaby Terminal is located in the Lower Fraser River Watershed of the Fraser River Basin. • The headwaters of Eagle Creek are within the existing property boundaries and will be within 30 m of planned work. Currently, watercourses are directed beneath the existing storage tanks via a below ground conveyance system, which will be expanded to accommodate the proposed storage tanks. Eagle Creek drains into Burnaby Lake, which flows south via Brunette River into the Fraser River. • The City of Burnaby and AECOM are collaborating to develop an Integrated Stormwater Management Plan (ISMP) for the watershed of Eagle Creek, in order to better manage land development and support environmental protection, preservation and enhancement of Eagle Creek and its tributaries. During an external stakeholder workshop for the Eagle Creek ISMP, recent studies conducted to provide an indication of the current state of water quality and quantity were summarized. Some key observations were the presence of low base flows in the late summer period, presence of iron oxide (likely naturally occurring) and downstream sedimentation, including at the Burnaby Lake inflow. The Eagle Creek ISMP will aim to address issues such as minimizing erosion and resulting problems with sedimentation in the lake, habitat enhancements, improving water quality in the stream and reducing pollution (Hill, Phang pers. comm.). The Eagle Creek ISMP is expected to be released in 2014. The potential effects of terminal construction and operation on the Eagle Creek drainage are assessed in Section 7.5.3.

TABLE 6.1-16 Cont'd

Environmental Elements	Summary of Considerations
Water Quality and Quantity (cont'd)	• Hydrostatic testing is planned for the piping and new tanks to be installed within the Burnaby Terminal. Water may be withdrawn and released from Trans Mountain's existing fire water pond at the Burnaby Terminal. Alternatively, test water may be diverted from a nearby river or creek, subject to obtaining a water withdrawal permit, or purchased from municipalities depending on availability from natural sources. Following testing, water will be tested for contaminants before being treated and either discharged back into the fire water pond, trucked away, or released to a natural water body or the municipal sewer system. • The terrain at the Burnaby Terminal is sloped and will require additional grading. The ground slopes down to the northeast across the site. Groundwater flow direction is inferred to be to the southwest. • The surficial geology beneath the site is mapped as Capilano sediments consisting of beach deposits of poorly-sorted sand to gravel normally less than 1 m thick (may be up to 8 m thick). The extreme northeast corner of the facility is underlain by Tertiary bedrock (Armstrong and Hicock 1980). • No water supply wells are mapped on the site or within the Water Quality and Quantity LSA. • Stantec Consulting Ltd. (2011) noted groundwater levels ranging from artesian (0.79 m above ground level) to 9.57 m bgl in on-site monitoring wells. • The southwestern corner of the Burnaby Terminal appears to overlie Aquifer #49, a moderately vulnerable aquifer, based on regional mapping (BC MOE 2013a).
Air Emissions	• Continuous VOC, H_2S and mercaptan emissions are primarily due to standing and working losses from existing product storage tanks at the Burnaby Terminal. • Fugitive emissions from leaks are expected to be a small contributor relative to emissions from existing tanks. • All existing pumps are electrically driven and are not direct sources of CACs. • CAC and VOC emissions from regular testing of emergency diesel generators and fire water pumps are infrequent. • The largest sources of CAC, except PM, in the Air Quality RSA are vehicle traffic, non-road engines and heating. The largest sources of PM emissions in the area are road dust and construction activities. The largest sources of VOC emissions are on-road motor vehicles and solvent evaporation. • Predicted VOC, H_2S and mercaptan concentrations in the Air Quality RSA due to existing operations at the Burnaby Terminal and other existing natural and anthropogenic sources are presented in the Air Quality and Greenhouse Gas Technical Report of Volume 5C.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Burnaby Terminal are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Products handled and stored in existing tanks contain trace levels of GHGs; small amounts might be released through fugitive or process emissions (*e.g.*, CH_4 and formation CO_2). • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Burnaby Terminal. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are traffic travelling along local arterial roadways and natural sound (*e.g.*, wind, wildlife). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is located approximately 50 m to the south of the fenceline of the Burnaby Terminal. • ASL in the absence of regulated energy facilities is approximately 38-41 dBA at night and 48-51 dBA during the day based on BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). • A measurement program was conducted at both the facility and representative ambient sound level at receptors surrounding the facility. The results of the receptor-based program gave a range of values between 42-49 dBA during nighttime and 45-49 dBA during the daytime. • A noise model was generated based on the sound level measurements of similar equipment at other Project locations as well as calculated sound levels based on equipment specifications. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Burnaby Terminal complies with the BC OGC *Noise Control Best Practices Guideline* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.

TABLE 6.1-16 Cont'd

Environmental Elements	Summary of Considerations
Fish and Fish Habitat	• The Burnaby Terminal is located in the Lower Fraser River Watershed of the Fraser River Basin. • The headwaters of Eagle Creek are within the existing property boundaries and will be within 30 m of planned work. Eagle Creek drains into Burnaby Lake, which eventually flows into the Fraser River. • All five BC indicator species (bull trout/Dolly Varden, rainbow trout/steelhead, cutthroat trout, coho salmon and Chinook salmon) are found in the Lower Fraser River Watershed. • Green sturgeon is a species of Special Concern under *SARA* (Environment Canada 2012) and is also Red-listed in BC (BC CDC 2013). Observations of green sturgeon in freshwater are rare, but there are some historical records in the Lower Fraser River (the most recent was near Fort Langley in 2005) (McPhail 2007). • Salish sucker and Nooksack dace are both Red-listed in BC (BC CDC 2013) and Endangered under *SARA* (Environment Canada 2012). Although both species are found in the Lower Fraser River Watershed, they have very limited distributions and there are no records of either species being found in Eagle Creek (COSEWIC 2002a, 2007a). However, Eagle Creek is a tributary to the Brunette River, which is known to support Nooksack dace (Fisheries [British Columbia] Technical Report of Volume 5C). • Westslope cutthroat trout is a species of Special Concern under *SARA* (Environment Canada 2012) and is also Blue-listed (BC CDC 2013). Westslope cutthroat trout is known to occur in the Lower Fraser River Watershed, however, this population is introduced and, therefore, not of conservation concern (see Table 4.4 of the Fisheries [British Columbia] Technical Report of Volume 5C). • Bull trout and mountain sucker may be found in the Lower Fraser River Watershed and are both listed as a Species of Special Concern under COSEWIC (2013) and are Blue-listed in BC (BC CDC 2013) (see Table 4.5 of the Fisheries [British Columbia] Technical Report of Volume 5C). • The Lower Fraser River population of white sturgeon is considered Threatened under COSEWIC (2013) and is Red-listed in BC (BC CDC 2013). • Chiselmouth has no federal listing (COSEWIC 2013, Environment Canada 2012) but is Blue-listed provincially (BC CDC 2013). • Eulachon is Endangered under COSEWIC (2013) and Blue-listed (BC CDC 2013) and may be found in the Lower Fraser River Watershed. • The Cultus Lake population of Sockeye salmon is Endangered under COSEWIC and is found in the Lower Fraser River Watershed, however, its range is limited to Cultus Lake, which is upstream of Project activities.
Wetland Loss or Alteration	• The Burnaby Terminal is located within the Lower Mainland ecoregion, a component of the Pacific Maritime ecozone of Canada. Wetter areas are characterized by Douglas-fir, western hemlock and western redcedar. Coastal salt marshes are located on the Fraser River delta and along Boundary Bay (Ecological Stratification Working Group 1995). • The Burnaby Terminal is also located within the Intermountain Prairie Wetland Region. Wetlands characteristic of this region include marshes bordering fresh to saline ephemeral or semi-permanent shallow waters (Government of Canada 1986). • The Burnaby Terminal is located within the CWH BGC Zone of BC. In this BGC Zone, wetlands are often found in depressions, around open water, small streams and drainage channels. Wetlands types include fens, marshes as well as shrubby swamps (BC MOF 1999, Meidinger and Pojar 1991). • Wetlands provide habitat for native plants and wildlife species, including nesting and foraging habitat for bird species as well as provide storage and natural filtering of water. • No wetlands were identified within or adjacent to the Burnaby Terminal during the helicopter reconnaissance and satellite imagery review. However, two artificial ponds are located within the vicinity of the Burnaby Terminal. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Burnaby Terminal. • The English Bay and Burrard Inlet IBA is located approximately 1.7 km north of the Burnaby Terminal (Bird Studies Canada and Nature Canada 2012). • The Burnaby Terminal is located within a DUC Level 2 Priority Area, the BC Coastal Areas and Estuaries (DUC 2013).
Vegetation	• The Burnaby Terminal is located within the Lower Mainland Ecoregion, a component of the Pacific Maritime Ecozone of Canada. This ecoregion is characterized by forests of Douglas-fir, western hemlock and western redcedar. Understories of shrubs, vines and moss are common in mature forests. Arbutus and dogwood communities are common on drier sites (Ecological Stratification Working Group 1995). • The Burnaby Terminal is located within the CWH BGC Zone of BC. The CWH BGC Zone is dominated by western hemlock, with western redcedar and Douglas-fir frequent throughout the zone. Amabilis fir, yellow-cedar, shore pine, grand fir, western white pine, bigleaf maple and black cottonwood are also common (Meidinger and Pojar 1991). • The Burnaby Terminal is adjacent to the Burnaby Mountain Conservation Area (City of Burnaby 2013). • Records of rare plant observations within 5 km of the Burnaby Terminal were acquired from the BC CDC (2013) database. No provincially-listed (BC CDC) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.

TABLE 6.1-16 Cont'd

Environmental Elements	Summary of Considerations
Wildlife and Wildlife Habitat	• The Burnaby Terminal does not lie within an LRMP region (BC MFLNRO 2008a). The Burnaby Terminal is located in the City of Burnaby, BC. • The Burnaby Terminal is located adjacent to existing tank facilities on industrial lands • The Burnaby Terminal is not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Burnaby Terminal is located in a DUC Level 2 Priority Area, the BC Coastal Areas and Estuaries (DUC 2013). • The English Bay and Burrard Inlet IBA is located approximately 1.7 km north of the Burnaby Terminal (Bird Studies Canada and Nature Canada 2012). • The Burnaby Terminal is adjacent to the Burnaby Mountain Conservation Area (City of Burnaby 2013). • The Burnaby Terminal is located in WMU 2-8 (BC ILMB 2006).
Species at Risk or Species of Special Status and Related Habitat	• The following federally-listed fish species are known to occur in the Lower Fraser River Watershed. See the Fish and Fish Habitat row of this table above for more details about each species (*e.g.*, distribution): – green sturgeon (*SARA*: Special Concern); – Salish sucker (*SARA*: Endangered); – Nooksack dace (*SARA*: Endangered); – bull trout (COSEWIC: Special Concern); – mountain sucker (COSEWIC: Special Concern); – white sturgeon (COSEWIC: Threatened); – eulachon (COSEWIC: Endangered); and – sockeye salmon (COSEWIC: Endangered). • Records of rare plant observations within 5 km of the Burnaby Terminal were acquired from the BC CDC (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Burnaby Terminal (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – olympic shrew (provincial: Red); – Pacific water shrew (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red); and – southern red-backed vole (*occidentalis* subspecies) (provincial: Red). • A search of the BC CDC database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Burnaby Terminal (BC CDC 2012, 2013). • Given that the Burnaby Terminal is an existing facility and all work will occur within the existing fenced area on previously disturbed land, the Burnaby Terminal is not considered suitable habitat for wildlife or plant species at risk.

6.2 Westridge Marine Terminal

The existing Westridge Marine Terminal is located at d-047-D/092-G-07 at RK 3.6 on reclaimed foreshore lands. The Westridge Marine Terminal is located in the municipal boundary of the City of Burnaby. It is located on approximately 6.2 ha of land owned by Trans Mountain, with the exception of a small portion of land located between the railway and the shoreline, which is leased from Canadian Pacific Railway (CPR). The facility also extends into Burrard Inlet. The expansion of the existing Westridge Marine Terminal will include the construction of one dock with three operational berths, as well as a utility dock. The existing water lease will need to be expanded to accommodate the new docks. Existing access to the Westridge Marine Terminal via Barnet Highway will be used. Table 6.2-1 provides a summary of the environmental elements and considerations for the Westridge Marine Terminal pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Westridge Marine Terminal is shown on Figure 6.1-16.

An LSA of 500 m extending from the proposed water lease expansion applies to marine sediment and water quality, marine fish and fish habitat, and marine mammals. The Marine Birds LSA extends 300 m from the proposed water lease expansion. The Marine RSA applies to all marine elements and includes the area of Burrard Inlet east of the First Narrows, including Indian Arm and Port Moody Arm. Study area boundaries for the marine elements at Westridge Marine Terminal are shown on Figures 6.2-1 to 6.2-2.

TABLE 6.2-1

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE WESTRIDGE MARINE TERMINAL

Environmental and Socio-Economic Elements	Summary of Considerations
Physical Environment	• The Westridge Marine Terminal is located within the Georgia Depression Physiographic Region, which is characterized by a flat valley floor 1-5 km wide, steep valley walls, gently rolling uplands and ridges, gently rolling to flat lowlands of terraces and plains, and deltas (Armstrong 1984, Holland 1976). • The Westridge Marine Terminal is likely underlain by coarse-grained clastics and volcanic rock types (BGC Engineering Inc. 2013c). • The surficial geology beneath the site is mapped as glaciofluvial (BGC Engineering Inc. 2013a). • There are no areas of permafrost within the area of the Westridge Marine Terminal (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Westridge Marine Terminal. • No volcanoes (NRCan 2010e) have been recorded in the vicinity of the Westridge Marine Terminal. • The site is located in a zone of high seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is between 0.4 and 0.5 g (NRCan 2013a). Several known and suspected post-glacial faults lie near the pump station. Major earthquakes (up to and over magnitude 7) have occurred in the Coast Mountains and Cascade Ranges around the pump station (NRCan 2013b). Refer to the Seismic Assessment Desktop Study of Volume 4A for additional information. • The topography in the area of the Westridge Marine Terminal is sloping from south (high) to the north (low) toward Burrard Inlet and the elevation ranges from approximately 30-0 m above sea level. • Where activities are planned within the Westridge Marine Terminal, soils have been disturbed for industrial use and construction of the new infrastructure will be conducted within the boundaries of the existing terminal. • A description of the climate for the CWH BGC Zone is provided in Section 5.1.3. • Meteorological data were obtained from an Environment Canada meteorological station (1108447) at Vancouver International Airport (Environment Canada 2013a). The data were taken approximately 20 km southwest of the Westridge Marine Terminal and are provided in Table 6.1-16. • No major tornadoes or hailstorms have been recorded in the vicinity of the Westridge Marine Terminal (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Westridge Marine Terminal will be conducted within an existing fenced, industrial site. Some topsoil/root zone material will be disturbed during construction activities. • Historical spills have been recorded at the Westridge Marine Terminal. No further assessment is required. If contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Westridge Marine Terminal EPP of Volume 6D) will be implemented. • Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water and groundwater quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*. • Marine sediment and water quality is discussed below in this table.
Air Emission	• Continuous VOC, H_2S and mercaptan emissions are primarily due to standing and working losses from existing product storage tanks and fugitive losses from marine vessel loading/unloading activities at the Westridge Marine Terminal. • Fugitive emissions from leaks are expected to be a small contributor relative to emissions from existing tanks and marine vessel loading/unloading activities. • Continuous CAC emissions are associated with marine vessels at berth and combustion of propane assist gas in the Vapour Combustion Unit used to destroy fugitive VOC losses from marine vessel loading/unloading activities. • All existing pumps are electrically driven and are not direct sources of CACs. • CAC and VOC emissions from regular testing of emergency diesel generators and fire water pumps are infrequent. • The largest sources of CAC, except PM, in the Air Quality RSA are vehicle and marine traffic, non-road engines and heating. The largest sources of PM emissions in the area are road dust and construction activities. The largest sources of VOC emissions are on-road motor vehicles, marine vessels and solvent evaporation. • Predicted VOC, H_2S and mercaptan concentrations in the Air Quality RSA due to existing operations at the Westridge Marine Terminal and other existing natural and anthropogenic sources are presented in the Air Quality and Greenhouse Gas Technical Report of Volume 5C.
Greenhouse Gas Emissions	• Indirect GHG emissions due to electric power consumption by the existing pumps at the Westridge Marine Terminal are the main emissions. These include emissions from fossil fuel combustion, unallocated energy from power line losses, metering differences and other losses, and emissions of SF_6 from gas handling and transferring operations, electrical equipment operation, and from equipment mechanical failures. • Products handled and stored in existing tanks contain trace levels of GHGs; small amounts might be released through fugitive or process emissions (*e.g.*, CH_4 and formation CO_2). • Products filled into and stored in ship hulls contain trace levels of GHGs; small amounts might be released through fugitive or process emissions (*e.g.*, CH_4 and formation CO_2). • Small amounts of direct GHG emissions will be released due to the space heating of the existing buildings at the Westridge Marine Terminal. • Small amounts of indirect GHG emissions will be released due to electricity use for equipment other than pumps. • Small amounts of GHG emissions will be released from the motor vehicles used by operations/maintenance staff.

TABLE 6.2-1 Cont'd

Environmental and Socio-Economic Elements	Summary of Considerations
Acoustic Environment	• Sources of existing sound in the Acoustic Environment LSA are vehicle traffic travelling along local arterial roadways, vessel traffic in Burrard inlet, energy facility and natural sound (*e.g.*, wind, wildlife, water). • Receptors were identified within the Acoustic Environment LSA. The nearest receptor is a private residence located approximately 75 m to the south of the fenceline of the Westridge Marine Terminal. • The BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) defined ASL in the absence of regulated energy facilities ranges between 46-51 dBA at night and 56-61 dBA during the day for urban settings. • A measurement program was conducted at both the facility and representative ambient sound level at receptors surrounding the facility. The results of the receptor-based program indicate existing sound levels in residential areas near the terminal range between 38-46 dBA during the nighttime and 44-51 dBA during the daytime. The levels reflect the amount of industrial sound from Westridge, neighbouring facilities and traffic already experienced by residents. • A noise model was generated based on the sound level measurements of similar equipment as well as calculated sound levels based on equipment specifications. Applicable buildings and shelters were modelled along with the appropriate insertion losses and screening effects. • The noise modelling results indicate that sound from the existing Westridge Marine Terminal complies with the BC OGC *Noise Control Best Practices Guideline* permissible sound levels for all surrounding receptors. • Contoured noise prediction results are available in the Terrestrial Noise and Vibration Technical Report of Volume 5C.
Wetland Loss or Alteration	• No wetlands were identified within or adjacent to the Westridge Marine Terminal and, therefore, detailed information on wetlands is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Vegetation	• No native vegetation is anticipated to be disturbed by the Project and, therefore, detailed information on vegetation is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Fish and Fish Habitat	• No work will occur within 30 m of any freshwater fish-bearing waterbodies and, therefore, detailed information on freshwater fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Marine fish and fish habitat is discussed below in this table.
Marine Sediment and Water Quality	• The Marine RSA is affected by a variety of historical and current human activities that have introduced contaminants that affect marine sediment and water quality. In some areas, contaminants are present at levels higher than applicable guidelines to protect marine life, but generally, sediment and water quality meet the guidelines. • Activities in the Marine RSA include vessel traffic, recreational boating, port facilities (petroleum products, bulk cargo, metal concentrates, coal, sulphur, sugar, wheat), Lions Gate Wastewater Treatment Plant effluent and urban runoff. There are 173 municipal storm water outfalls, 13 combined sanitary and storm water outfalls, several emergency sanitary system outfalls (for sanitary sewer overflows and lift station overflows), 31 BC MOE-permitted effluent outfalls for industries, and a number of oil interceptors. Numerous streams draining residential, commercial and industrial areas also enter Burrard Inlet and may convey contaminants. • Shoreline areas, mainly near the Westridge Marine Terminal east of the Second Narrows, were affected by the release of crude oil from the accidental rupture of the Trans Mountain pipeline in 2007, when oil entered Burrard Inlet through several storm drain outfalls; oil was removed during the immediate spill response and remediation efforts in 2007 and 2008 (Stantec Consulting Ltd. 2010, 2012). • Marine sediment and marine water quality were selected as indicators for the assessment of Project-related effects associated with construction and operations of the Westridge Marine Terminal. • Contaminants of potential concern associated with the Westridge Marine Terminal are related to hydrocarbons (shipment of oil, ambient sources) and also metals and historical contaminants such as PCBs (from ambient sources not related to construction or operation of the Westridge Marine Terminal, but which could be disturbed during dredging for construction). • Total polycyclic aromatic hydrocarbon (PAH) levels are compared to draft sediment quality objectives for Burrard Inlet (1.68 µg/g) (Swain 2009) and screening criterion for disposal at sea (2.5 µg/g) (Environment Canada 2013c), and some areas have PAH levels higher than these objectives and criteria. • Total PAH levels in subtidal sediment of the Marine RSA (nearshore samples from eight sites in 2002) ranged from 1.0-3.3 µg/g, with three samples (Loch Katrine, Clark Drive, and Vancouver Wharves, between the First Narrows and Second Narrows) higher than the 2.5 µg/g criterion (BC Ministry of Water, Land and Air Protection [MWLAP] 2004). Total PAH levels were also monitored from 2007 through 2011 at three subtidal sites after the 2007 oil release (Barnet Marine Park, Westridge and Berry Point); levels were higher than the screening criterion at all three sites (maximum of 3.97 µg/g) in 2007 and at Westridge and Barnet Marine Park in subsequent years (range of 1.6-11.4 µg/g), assumed to reflect ambient conditions, as PAH composition reflected a variety of hydrocarbon sources. • Subtidal sediment in the Marine Sediment and Water Quality LSA at the existing Westridge Marine Terminal historically contained elevated levels of PAHs (0.01-9 µg/g, with two isolated samples up to 130 µg/g in 2005); contaminated sediment was removed in 2006 during maintenance dredging at the Westridge Marine Terminal (BGC Engineering Inc. 2006). Field surveys conducted in 2013 in the Marine Sediment and Water Quality LSA indicated total PAH levels of < 0.2-3.66 µg/g, with 1 of 39 samples higher than the screening criterion.

TABLE 6.2-1 Cont'd

Environmental and Socio-Economic Elements	Summary of Considerations
Marine Sediment and Water Quality (cont'd)	• Total PAH in intertidal sediment around the Westridge Marine Terminal was affected by the 2007 accidental release of oil, which entered the Inlet through storm sewer outfalls; levels were elevated (up to 30.3 µg/g in July 2007), and were reduced following clean-up in 2007 and remediation in 2008. Most of the samples from Westridge and other areas of Burrard Inlet met the sediment quality objective in 2008 and later years, although higher levels were noted consistently for Maplewood Flats (unrelated to the spill, likely originating from historical industrial activities). • Total polychlorinated biphenyls (PCBs) in subtidal sediment were measured at three locations in the Marine RSA between 1985 and 2004 (BC MWLAP 2004, BGC Engineering Inc. 2006, Jacques Whitford AXYS 2008) and in 2005 at the Westridge Marine Terminal (BGC Engineering Inc. 2006). Most of the samples had concentrations lower than the *Disposal at Sea Regulations* screening criterion of 0.1 µg/g and CCME ISQG of 0.0215 µg/g, although 1 of 38 samples collected at the Westridge Marine Terminal in 2005 had a concentration of 4.5 µg/g (later removed during dredging) and 1 of 8 samples collected throughout Burrard Inlet in 2002 had a concentration of 0.2 µg/g. Field surveys conducted in 2013 in the Westridge Marine Terminal area indicated total PCB levels of < 0.02-0.276 µg/g, with 1 of 39 samples higher than the screening criterion. • Metal levels in subtidal sediment near the Westridge Marine Terminal were measured in 2005 (BGC Engineering Inc. 2006) and 2013 (see the Marine Sediment and Water Quality – Westridge Marine Terminal Technical Report of Volume 5C) and in the Marine RSA in 2002 (BC MWLAP 2004). Levels of several metals were higher than the Canadian Council of Ministers of the Environment (CCME) Interim Sediment Quality Guideline (ISQG) and disposal at sea screening criteria, reflecting natural conditions (arsenic, copper) and human activities (cadmium, copper, lead, mercury, zinc). In areas east of the Second Narrows, including the Project Footprint and the Marine Sediment and Water Quality LSA, the reported levels were well below the CCME Probable Effects Levels (PEL). However, in localized areas west of the Second Narrows, copper and zinc levels were higher than the PEL at Vancouver Wharves (which handles mineral concentrates) and copper was above the PEL at Clark Drive (near a combined storm water and sanitary outfall), reflecting the strong influence of particular human activities. • Water quality was assessed at four locations during fall 2002 for the Burrard Inlet Objectives Attainment program (BC MWLAP 2004), with samples collected for general parameters, metals and total suspended solids (TSS). Copper, iron, lead and manganese levels were below BC guidelines in all samples. Zinc levels were just above the BC maximum water quality guideline in one sample (Pacific Coast Terminal, November 2002). • In May 2013, water samples were collected during the field survey for the Project, at one location near the Westridge Marine Terminal (at 1 m depth and at 1 m above the sediment) and analyzed for general chemistry, metals, nutrients, TSS and hydrocarbons. Samples collected on incoming (flood) and outgoing (ebb) tides had metal levels lower than water quality guidelines for the protection of marine life (BC MOE 2013c, CCME 2013), with the exception of zinc in shallow ebb tide water (slightly above BC MOE guidelines). All organic parameters associated with hydrocarbons were below detection limits. • More detailed information on marine sediment and water quality in the Marine Sediment and Water Quality LSA and the Marine RSA is provided in the Marine Sediment and Water Quality – Westridge Marine Terminal Technical Report of Volume 5C.
Marine Fish and Fish Habitat	• Burrard Inlet is approximately 50 km in length and ranges from 0.5–3 km in width. It includes over 11,000 ha of water and seabed, 190 km of shoreline, and a drainage basin of 98,000 ha (Stantec Consulting Ltd. 2009). • Maximum water depth in Burrard Inlet is approximately 220 m, which is found in the deep basin of Indian Arm. English Bay and the Harbour are shallower, with typical water depths of 25-35 m and a maximum depth of approximately 65 m. The mean tidal range in the Inlet is 3.3 m. Currents vary according to location, with the highest velocities occurring at locations where the Inlet narrows, constricting water movement. Maximum currents at the First Narrows are on the order of 5.5 knots. • At least 75 species of fish are known to use Burrard Inlet including a number of species targeted in commercial, recreational, and Aboriginal fisheries such as all five species of Pacific salmon, Pacific herring, anchovy, lingcod, copper rockfish, quillback rockfish, and kelp greenling (Hanrahan 1994 in Haggarty 2001, Renyard 1988). • Three marine fish habitats and three marine fish species were selected as indicators for the assessment of Project-related effects associated with construction and operations of the Westridge Marine Terminal. These are: marine riparian habitat; intertidal habitat; subtidal habitat; Dungeness crab; inshore rockfish; and Pacific salmon. • Marine riparian, intertidal, and subtidal habitats are used by marine fish and invertebrates for spawning, rearing, migration, and foraging (Healey 1980, Lemieux *et al.* 2004, Levings and Jamieson 2001, Levings and Thom 1994). • The total length of shoreline in the Marine Fish and Fish Habitat LSA is 2.3 km. 'Man-made' is the most common shore type in the Marine Fish and Fish Habitat LSA covering 1.04 km and 44.5% of the total shoreline (BC ILMB 2005). The total length of shoreline in the Marine RSA is 157.5 km. 'Man-made' is also the most common shore type in the Marine RSA covering 53.5 km and 33.9% of the total shoreline (BC ILMB 2005). Subtidal habitats of Burrard Inlet are dominated by soft, muddy substrates (BC Marine Conservation Analysis 2009, Burd 1990, Burd *et al.* 2008). Adult Pacific salmon have been observed to return to at least 17 streams in Burrard Inlet, 12 of which are located in the Marine RSA (BC MOE 2013d, Haggarty 2001). Four populations of Pacific salmon have been designated as species of conservation concern by COSEWIC, however, none of these populations spawn in streams entering Burrard Inlet (COSEWIC 2002b, 2003a,b, 2006). Burrard Inlet has been identified as a Fisheries and Oceans Canada (DFO) Important Area for Pacific salmon which overlaps with the Marine RSA (Jamieson and Levesque 2012a,b). • Quillback rockfish and copper rockfish are the most likely rockfish species to occur in Burrard Inlet (Renyard 1988). The quillback rockfish has been designated as Threatened by COSEWIC but is not currently listed under *SARA* (COSEWIC 2009). The copper rockfish has not been identified as a species of conservation concern.

TABLE 6.2-1 Cont'd

Environmental and Socio-Economic Elements	Summary of Considerations
Marine Fish and Fish Habitat (cont'd)	• Three Rockfish Conservation Areas (RCAs) overlap with the Marine RSA including Indian Arm – Crocker Island RCA, Indian Arm – Twin Islands RCA, and Eastern Burrard Inlet RCA. The Marine Fish and Fish Habitat LSA overlaps with the Eastern Burrard Inlet RCA. • Dungeness crabs are common in Burrard Inlet and are expected to occur within the Marine Fish and Fish Habitat LSA and Marine RSA throughout the year (DFO 2012, Jamieson and Levesque 2012a,b). Several areas in eastern Burrard Inlet have been identified as DFO Important Areas for Dungeness crab, one of which overlaps with the Marine Fish and Fish Habitat LSA (Jamieson and Levesque 2012a,b). • A survey of marine riparian habitat in the Marine Fish and Fish Habitat LSA was conducted on September 26, 2012. Riparian habitats have been extensively modified by historical development activities, including the original construction of the Westridge Marine Terminal in 1954. Riparian vegetation at the Westridge Marine Terminal is limited to a narrow fringe of small shrubs and low growing vegetation. Second-growth deciduous trees are found to the north and south of the Westridge Marine Terminal, along the shoreline adjacent to the Canadian National (CN) rail line. A total of 38 vascular plant species were identified during the survey. • A survey of intertidal habitat in the Marine Fish and Fish Habitat LSA was conducted from August 18 to 19, 2012. The intertidal zone is dominated by coarse substrate types, particularly boulder and cobble riprap. Two shore types were identified in the intertidal zone including man-made rock ramps and rock cliffs. A total of 17 marine invertebrate species and 8 marine algae species were identified. The most common sessile invertebrate species were common acorn barnacles and blue mussels, and the most common motile invertebrate species were periwinkles and limpets. The most common algae species were rockweed, Turkish washcloth and green ribbon. • A camera-mounted remotely-operated vehicle (ROV) was used to survey subtidal habitat in the Marine Fish and Fish Habitat LSA from September 17 to 20, 2012. The substrate observed consisted almost entirely of soft bottom (silt, mud, sand) with traces of broken shells and wood debris. A small section of steeply-sloping rip-rap was identified inshore of the existing berth. A total of 32 species of fish and invertebrates were observed. Brown bladed algae were the dominant algal species in the survey area. Dungeness crabs were very abundant and red rock crabs were moderately abundant. Demersal fish of the family *Stichaeidae* and various flatfish were very abundant on soft bottom habitat. Shiner perch, pile perch and kelp perch were moderately abundant in the shallow rip-rap and around pilings. • More detailed information on marine riparian habitat, intertidal habitat, subtidal habitat, Pacific salmon, rockfish and Dungeness crab in the Marine Fish and Fish Habitat LSA and Marine RSA is provided in the Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C.
Wildlife and Wildlife Habitat	• The Westridge Marine Terminal is located in the City of Burnaby in the Greater Vancouver Regional District (GVRD). • The Westridge Marine Terminal is partially located on reclaimed foreshore lands. All terrestrial work will be conducted within the existing fenced area. • The Westridge Marine Terminal is not located within or adjacent to any provincial parks or protected areas (BC MFLNRO 2008b), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), designated caribou range (BC MOE 2008), ungulate winter range (BC MOE 2005a), or Wildlife Habitat Areas (BC MOE 2005b). • The Westridge Marine Terminal is located at the edge of the English Bay and Burrard Inlet IBA (Bird Studies Canada and Nature Canada 2012). • The Burnaby Mountain Conservation Area is approximately 240 m from the Westridge Marine Terminal and Barnet Marine Park is adjacent to the eastern boundary of the terminal. • The Westridge Marine Terminal is located in a DUC Level 2 Priority Area, the BC Coastal Areas and Estuaries (DUC 2013). • The Westridge Marine Terminal is located in WMU 2-8 (BC ILMB 2006).
Marine Mammals	• Marine mammal diversity and abundance in Burrard Inlet is generally considered low. • The most abundant and commonly observed species by far is the Pacific harbour seal, which is resident within the Inlet and throughout the coastal waters of BC (DFO 2010, Hanrahan 1994 in Haggarty 2001). Harbour seals were selected as the representative marine mammal indicator for the assessment of Project-related effects associated with construction and operations of the Westridge Marine Terminal. • Over the years, there have been occasional but rare sightings in Burrard Inlet of other marine mammal species such as Steller and California sea lions, northern fur seal and harbour porpoise (Marine Mammal Research Unit 2012). Killer whale, Pacific white-sided dolphin, false killer whale, grey whale, humpback whale, and minke whale have also made the occasional appearance in Burrard Inlet or nearby waters (BC Cetacean Sightings Network 2013), though their use of this habitat is limited and sightings are relatively uncommon. • No marine mammal field work was conducted for the Project, as available information suggests that aside from harbour seals, marine mammal diversity and abundance in Burrard Inlet is low. • Harbour seals use both aquatic and terrestrial environments and do not migrate but instead reside in BC's coastal waters and inlets year-round (Baird 2001, Bigg 1981, DFO 2010). They are likely the most commonly-sighted marine mammal in BC and prefer nearshore habitats including sounds, inlets, straits, marinas and harbours; they have also been known to occur in river estuaries (Baird 2001). Terrestrial haul out sites are used for resting, mating and pupping, and include isolated rocks or islets, sandbars, log booms, and recreational floats (Baird 2001).

TABLE 6.2-1 Cont'd

Environmental and Socio-Economic Elements	Summary of Considerations
Marine Mammals (cont'd)	• No DFO Important Areas for marine mammals have been identified in the Marine RSA (Jamieson and Levesque 2012a,b). • More detailed information on harbour seals in the Marine Mammal LSA and Marine RSA is provided in the Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C.
Marine Birds	• Information on marine bird and habitat use within the Marine RSA was primarily derived from a review of relevant literature and databases from peer-reviewed journals, agency publications, technical reports (*e.g.,* COSEWIC status reports), and local and regional data (*e.g.,* Bird Studies Canada, BC Coastal Waterbird Survey, BC Breeding Bird Atlas, BC Marine Bird Atlas, Project Feederwatch, Great Backyard Bird Count, eBird). Data from 45 years of North American Breeding Bird Survey data and 14 years of overwintering BC Coastal Waterbirds Survey data was used to characterize the marine bird use of the Marine RSA. Key sources include Birds of Burrard Inlet (Breault and Watts 1996, Burrard Inlet Environmental Action Program [BIEAP] 2002) and the IBAs program coordinated by BirdLife International (2013). • Indicator species selected to represent potential effects from Project activities at the Westridge Marine Terminal are: bald eagle; great blue heron; pelagic cormorant; Barrow's goldeneye; glaucous-winged gull; and spotted sandpiper. Each of these six species represents a foraging guild within an overall diverse group of marine birds, using a range of niches within the marine and coastal habitats present within the Marine RSA boundaries. More detailed information on these marine bird indicators' use of habitats in the Marine Bird LSA and Marine RSA is provided in the Marine Birds – Westridge Marine Terminal Technical Report of Volume 5C. • Bald eagles are relatively abundant and nest in large mature trees at approximately 15 locations, with an average of 3.45 km between nests, along the shores of Burrard Inlet, Indian Arm and Port Moody Arm. They have large home ranges and high nest site fidelity. It is suggested that they are a primary reason for the decline of some marine bird breeding colonies in the Marine RSA (Cook 2008) and despite increasing human disturbance, their numbers are increasing. • A great blue heron breeding colony has been active for many years in Stanley Park (187 breeding individuals recorded in 2007). A smaller colony is also located on Heron Creek several kilometres upstream of the Westridge Marine Terminal near Cliff Avenue, Burnaby. • Within Burrard Inlet, breeding colonies of pelagic cormorants have been identified at Second Narrows, Prospect Point, and occasionally the Burrard dry dock facility (Chatwin *et al*. 2002, Campbell *et al.* 1990, Hobson and Wilson 1985, Vermeer and Rankin 1984). • Glaucous-winged gulls nest on the roofs of buildings and the supports of the Ironworkers Memorial Second Narrows Crossing (Hobson and Wilson 1985, Vermeer *et al.* 1988). In the Marine RSA, they are abundant and widespread in all seasons, breeding at 5 or more seasonal colonies in the RSA with up to 250 pairs at each site. The closest known colony to the Project footprint is to the east approximately 1 km from the Westridge Marine Terminal and located on the south shoreline at the entrance to Port Moody Arm. • Long-term data sets of marine bird distribution and abundance in the Marine RSA indicate a total of 121 different waterbird species are present seasonally. Field studies were completed in the Marine Bird LSA on October 17, 2012, and on January 16, April 9 and July 15, 2013. These surveys were intended to validate and/or update existing information on marine bird seasonal distribution and abundance in the Marine Bird LSA. Field studies included a structured shore-based survey at stationary points and were supplemented with incidental observations. • A total of 405 individuals of 25 species were recorded during both 2012 and 2013 surveys. Species of concern observed were the Red-listed pelagic cormorant, and the following Blue-listed species: double-crested cormorant; surf scoter; California gull; and great blue heron (also listed in Schedule 1 of *SARA* as of Special Concern). • Burrard Inlet is part of the English Bay and Burrard Inlet IBA (IBA020) (Bird Studies Canada and Nature Canada 2013, BirdLife International 2013). The IBA is globally important for western grebes, Barrow's goldeneye and surf scoter, and is nationally important for great blue heron (BIEAP 2002, BirdLife International 2013). • Tens of thousands of migratory birds stop in Burrard Inlet along the Pacific Flyway. Parks that border the Inlet include Indian Arm Provincial Park, Belcarra Regional Park and Stanley Park. There are extensive tidal flats, remnant mudflats and saltwater marshes at Maplewood Conservation Area and Port Moody Inlet. Maplewood Flats, located west across Burrard Inlet from the Westridge Marine Terminal approximately 4 km, is regionally known for its importance as a conservation area for greater than 200 species of aquatic and terrestrial birds including the rare passerine, purple martin, which nests in nestboxes installed on pilings offshore in the Inlet. Maplewood Flats has the largest area of tidal mudflats on the Lower Mainland North Shore. • Bird abundance in Burrard Inlet has been recorded at more than 24,000 birds during the peak of spring migration (Breault and Watts 1996, BIEAP 2002). The marine areas of the Central Harbour typically have the greatest abundance of waterbirds within the Inlet. The highest diversity of species has been recorded at Port Moody, First Narrows and Second Narrows (Breault and Watts 1996).

TABLE 6.2-1 Cont'd

Environmental and Socio-Economic Elements	Summary of Considerations
Marine and Terrestrial Species at Risk or Species of Special Status and Related Habitat	<u>Onshore and Freshwater Species</u> • No work will occur within 30 m of any freshwater fish-bearing waterbodies and, therefore, detailed information on freshwater fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • No federally-listed (*SARA* or COSEWIC) plant species records were found within the Westridge Marine Terminal. • Based on known species range and habitat preferences, the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species were identified as having the potential to occur in the vicinity of the Westridge Marine Terminal (BC MOE 2013b, COSEWIC 2013, Environment Canada 2012): – great blue heron (*fannini* subspecies) (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); and – Pacific water shrew (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red). • A search of the BC CDC database identified the following federally-listed (*SARA* Schedule 1 or COSEWIC) or provincially-listed (Red, Blue, or under BC's *Wildlife Act*) wildlife species within 2 km of the Westridge Marine Terminal (BC CDC 2012, 2013): – great blue heron (*fannini* subspecies) (*SARA*: Special Concern, COSEWIC: Special Concern, provincial: Blue); and – Pacific water shrew (*SARA*: Endangered, COSEWIC: Endangered, provincial: Red). • Given that the Westridge Marine Terminal is an existing facility and all terrestrial work will occur within the existing fenced area, the Westridge Marine Terminal is not considered suitable habitat for wildlife or plant species at risk (excluding marine wildlife). <u>Marine Species</u> • There are two marine fish species of conservation concern that are likely to be found in the Marine RSA: quillback rockfish (Threatened, COSEWIC 2009); and spiny dogfish (Special Concern, COSEWIC 2011a). Yelloweye rockfish (Special Concern, COSEWIC 2008) may also occur within the Marine RSA at very low abundance. • Other fish species that are considered unlikely to occur in the Marine RSA but which have inferred ranges that overlap Burrard Inlet are: bluntnose sixgill shark (Special Concern, COSEWIC 2007b; Special Concern under *SARA*, Environment Canada 2012), Bocaccio (Threatened, COSEWIC 2002c), green sturgeon (Special Concern, COSEWIC 2004), eulachon – Fraser River population (Endangered, COSEWIC 2011b), coho salmon – Interior Fraser population (Endangered, COSEWIC 2002b); and sockeye salmon – Cultus population (Endangered, COSEWIC 2003a). • The following *SARA*-listed marine mammal species may occasionally be observed in the Marine RSA: Steller sea lion (Special Concern), harbour porpoise (Special Concern), southern resident killer whale (Endangered), Bigg's (previously transient) killer whale (Threatened), grey whale (Special Concern) and humpback whale (Threatened) (BC Cetacean Sightings Network 2013, Environment Canada 2012, Marine Mammal Research Unit 2012). Additionally, the northern fur seal is listed as Threatened by COSEWIC (Environment Canada 2012). None of these species are considered particularly common or abundant in the Marine RSA. • Based on a review of COSEWIC (2013), the federal *SARA* public registry list (Schedule 1) (Environment Canada 2012) and the BC CDC (2013) Red and Blue-lists, 21 marine bird species of conservation concern could occur seasonally within the Marine RSA due to range overlap (including migration) (Section 3.21, Table 3.1 of the Marine Birds - Westridge Marine Terminal Technical Report of Volume 5C). Under the BC *Wildlife Act*, 17 of these species are designated as Blue-listed (Special Concern) and 4 are designated as Red-listed (Endangered or Threatened). Under *SARA*, four of these species are considered Threatened and four are of Special Concern. Of the six indicators selected to represent marine birds, the pelagic cormorant is provincially Red-listed and the great blue heron is both provincially Blue-listed and designated under COSEWIC and Schedule 1 of *SARA* as a species of Special Concern.

6.3 Reactivated Pump Stations

As an outcome of the pipeline expansion, the Niton Pump Station will be reactivated (currently deactivated) to serve the existing pipeline. Reactivation activities will be conducted within the current fenced areas and no new disturbance will be required.

6.3.1 Niton Pump Station

The existing Niton Pump Station is located at SW 34-53-13 W5M at RK 191.4 on lands owned by Trans Mountain in Yellowhead County. Current land use at and around this facility site is industrial. Access to the Niton Pump Station is via Highway 16. Table 6.3-1 provides a summary of the environmental elements and considerations for the Niton Pump Station pursuant to Guide A.2.4 and Table A-2 of the NEB *Filing Manual*. The location of the Niton Pump Station is shown on Figure 6.3-1.

TABLE 6.3-1

SUMMARY OF ENVIRONMENTAL ELEMENTS AND CONSIDERATIONS FOR THE NITON PUMP STATION

Environmental Elements	Summary of Considerations
Physical and Meteorological Environment	• The Niton Pump Station is located within the Western Alberta Plains Physiographic Region, characterized by undulating plains, less abundant hummocky terrain and incised river valleys (Natural Regions Committee 2006a, Pettapiece 1986). • The Niton Pump Station is underlain by the Paskapoo Formation, which is characterized by a thick sequence of Paleocene sand and siltstones, consisting of buff medium-grained sandstone overlain by interbedded light grey soft sandy siltstone and mudstones (Dawson *et al*. 1994, Hamblin 2004). • Surficial deposits at the Niton Pump Station are till and glaciolacustrine sediments with lesser active fluvial, glaciofluvial, deltaic, eolian and ice-thrust moraine deposits (Natural Regions Committee 2006a, Roed 1975, Shetsen 1990). • There are no areas of permafrost within the area of the Niton Pump Station (refer to Section 5.1.1). • No areas of potential terrain instability are known to occur in the vicinity of the Niton Pump Station. • The site is located in a zone of low seismic activity (NRCan 2010a). Peak ground acceleration with a 1:2475 annual probability of exceedance is less than 0.1 g (NRCan 2013a). No earthquakes have been recorded in the area (NRCan 2013b). • The topography in the area of the Niton Pump Station is generally flat and elevation is approximately 860 m above sea level. • Where reactivation activities are planned within the Niton Pump Station, soils have been disturbed for industrial use and any reactivation activities will be conducted within the boundaries of the existing station. • The Niton Pump Station is located in an agricultural area considered to have low soil erosion risk (AARD 2005a). Wind erosion risk, which assesses the risk of soil degradation by wind on bare, unprotected mineral soil, is considered low at the pump station (AARD 2005b). Water erosion risk, which assesses the risk of soil degradation by water on bare, unprotected mineral soil, is considered severe in the vicinity of the site (AARD 2005c). • A description of the climate for the Lower Foothills Natural Subregion is provided in Section 5.1.1. • Meteorological data from Environment Canada's Edson Station, located approximately 45 km west of the Niton Pump Station, are provided in Section 5.1.1. • No major tornadoes or hailstorms have been recorded in the vicinity of the Niton Pump Station (NRCan 2010b,c).
Soil and Soil Productivity	• Activities at the Niton Pump Station will be conducted within an existing fenced, industrial site lacking topsoil and, therefore, detailed soil information is not warranted as per Table A-2 of the NEB *Filing Manual*. • No contamination is anticipated at the Niton Pump Station. If any contamination is encountered during construction, the Contamination Discovery Contingency Plan (Appendix B of the Facilities EPP of Volume 6C) will be implemented. Potential soil contaminants of concern include gasoline, diesel fuel, lubricants and hydraulic fuels.
Water Quality and Quantity	• The Niton Pump Station is located in the Pembina River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any waterbodies and, therefore, detailed information on surface water quality and quantity is not warranted as per Table A-1 of the NEB *Filing Manual*.
Air Emissions	• This pump station is currently not active. Therefore, no fugitive air emissions are expected to occur unless the station is reactivated. • Air quality in the area surrounding the Niton Pump Station is expected to be primarily influenced by vehicle traffic emissions along Highway 5, the Community of Carrot Creek, and several oil and gas facilities.
Greenhouse Gas Emissions	• This pump station is currently not active. Therefore, no GHG emissions are expected to occur unless the station is reactivated.
Acoustic Environment	• Niton Pump Station will have no new noise sources added. • Sound from the reactivated station will be the same as sound experienced historically when the station was previously in operation. • A detailed analysis was not completed since no change from historical levels is expected.
Fish and Fish Habitat	• The Niton Pump Station is located in the Pembina River Watershed of the Athabasca River Basin. • No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish habitat is not deemed warranted as per Table A-1 of the NEB *Filing Manual*.
Wetland Loss or Alteration	• The Niton Pump Station is situated within the boundaries of the Boreal Transition Ecoregion of the Boreal Plains Ecozone. Small lakes, ponds and marshes occupy shallow depressions within this ecoregion (Ecological Stratification Working Group 1995). • The Niton Pump Station is also located in the Continental Mid-boreal Wetland Region. Wetlands characteristic of this region include flat and basin bogs often associated with horizontal and ribbed fens. Plateau bogs occur occasionally in large fens. Marshes can be found along gently sloping lakeshores (Government of Canada 1986). • The Niton Pump Station is located within the Lower Foothills Natural Subregion of the Foothills Natural Region. Wetlands are predominantly treed fens, bogs and open fens (Natural Regions Committee 2006b). • No wetlands were identified within or adjacent to the Niton Pump Station during the helicopter reconnaissance and satellite imagery review. As a result, a ground-based wetland survey was determined not to be required. • There are no Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), IBAs (Bird Studies Canada and Nature Canada 2012), Western Hemisphere Shorebird Reserves (WHSRN 2013) or Migratory Bird Sanctuaries (Environment Canada 2013b) located within the Wetland LSA surrounding the Niton Pump Station. • The Niton Pump Station is located within the DUC Level 1 Priority Area, the Prairie Pothole Region and Western Boreal Forest (DUC 2013).

TABLE 6.3-1 Cont'd

Environmental Elements	Summary of Considerations
Vegetation	• The Niton Pump Station is located within the boundaries of the Boreal Transition Ecoregion of the Boreal Plains Ecozone. In its native state, this ecoregion is characterized by trembling aspen, balsam poplar, white spruce, balsam fir and a thick understory of tall shrubs and herbs. Poorly-drained areas support communities of willow species and sedges, with black spruce and tamarack occurring occasionally (Ecological Stratification Working Group 1995). • The Niton Pump Station is located in the Lower Foothills Natural Subregion of the Foothills Natural Region. The Lower Foothills Natural Subregion is dominated by mixed stands of trembling aspen, lodgepole pine, white spruce and balsam poplar. Understory communities are dominated by shrubs and herbs (Natural Regions Committee 2006a). • There are no national parks, provincial parks, provincial recreation areas, Environmentally Significant Areas or other protected areas located within the Vegetation LSA near the Niton Pump Station. • Records of rare plant observations within 5 km of the Niton Pump Station were acquired from the ACIMS (2013) database. No provincially-listed (ACIMS) species records were found within the boundaries of the Vegetation LSA. • It was determined with satellite imagery interpretation that no native vegetation would be directly disturbed within the site boundaries and, therefore, a ground-based vegetation survey was deemed unnecessary. • Consultation with local agricultural authorities was conducted to determine weed species of concern for the region. See Section 4.4 of the Vegetation Technical Report of Volume 5C for a summary of these communications.
Wildlife and Wildlife Habitat	• The Niton Pump Station is not located within or adjacent to any Environmentally Significant Areas (ATPR 2009), provincial parks or protected areas (ATPR 2012), IBAs (Bird Studies Canada and Nature Canada 2012), Migratory Bird Sanctuaries (Environment Canada 2013b), National Wildlife Areas (Environment Canada 2013b), Western Hemisphere Shorebird Reserves (WHSRN 2013), Ramsar Wetlands of International Importance (Bureau of the Convention on Wetlands 2013), World Biosphere Reserves (UNESCO 2013), or provincially identified wildlife areas (AESRD 2013b).
Species at Risk or Species of Special Status and Related Habitat	• No work will occur within 30 m of any fish-bearing waterbodies and, therefore, detailed information on fish and fish species at risk is not deemed warranted as per Table A-1 of the NEB *Filing Manual*. • Records of rare plant observations within 5 km of the Niton Pump Station were acquired from the ACIMS (2013) database. No federally-listed (*SARA* or COSEWIC) species records were found within these boundaries. • A search of the AESRD FWMIS database did not identify any federally-listed (*SARA* Schedule 1 or COSEWIC) and/or provincially-listed (At Risk, May be at Risk, or under Alberta's *Wildlife Act* and *Wildlife Regulation*) wildlife species within 2 km of the Niton Pump Station (AESRD 2013c). • Given that the Niton Pump Station is an existing facility and all work will occur within the existing fenced area on previously disturbed land, the Niton Pump Station is not considered suitable habitat for wildlife or plant species at risk.

6.4 Temporary Facilities

The locations of potential temporary facilities (*e.g.*, staging and stockpile sites, equipment storage sites, construction work camps) will be determined as far in advance of construction as practical to allow adequate time to choose and evaluate any alternate sites. Wherever practical, the temporary facilities will be located on previously disturbed areas to minimize overall Project disturbance. All temporary facility sites will be reviewed from an environmental perspective prior to their use.

7.0 ENVIRONMENTAL EFFECTS ASSESSMENT

The description of the environmental setting (current state of the environment) within the Project area (Sections 5.0 and 6.0), is compared against the project description (Section 2.0) to assess potential environmental effects that might be caused by the Project. The environmental effects assessment uses the information provided in the environmental setting and Project description to:

- evaluate the environmental elements of importance in the Project area;
- identify and evaluate potential Project effects associated with each environmental element of importance; and
- develop appropriate technically and economically feasible site-specific mitigation.

In addition, the environmental effects assessment determines the significance of potential residual effects resulting from construction and operations activities after taking into consideration proposed mitigation measures. Trans Mountain has informed TERA that it will adopt the recommendations herein.

7.1 Methodology

The assessment evaluates the environmental effects of the construction (including reactivation/modification), operations, decommissioning and abandonment phases of each component of the Project. The assessment method includes the following steps.

1. Describe the environmental setting.
2. Identify key environmental elements that could be affected.
3. Define the indicators and measurement endpoints to be used to assess each element.
4. Determine spatial and temporal boundaries for each element.
5. Identify potential environmental effects for each indicator.
6. Develop appropriate technically and economically feasible site-specific mitigation and, where warranted, restitution measures that are technically and economically feasible.
7. Predict anticipated residual effects.
8. Determine the significance of residual effects.

Steps 2 to 8 are described below in the applicable Methodology subsection. This environmental effects assessment methodology is based on:

- *The Responsible Authority's Guide to the Canadian Environmental Assessment Act: Part II The Practitioner's Guide* (Federal Environmental Assessment Review Office [FEARO] 1994a);
- FEARO's *A Reference Guide for the Canadian Environmental Assessment Act: Addressing Cumulative Environmental Effects* (FEARO 1994b);
- FEARO's *A Reference Guide for the Canadian Environmental Assessment Act: Determining Whether a Project is Likely to Cause Significant Environmental Effects* (FEARO 1994c);
- the Canadian Environmental Assessment (CEA) Agency *Cumulative Effects Assessment Practitioners Guide* (Hegmann *et al.* 1999);
- CEA Agency's *Incorporating Climate Change Considerations in Environmental Assessment* (CEA Agency 2003);
- CEA Agency's *Addressing Cumulative Environmental Effects under the Canadian Environmental Assessment Act, 2012* (CEA Agency 2013);
- the *CEA Act, 2012*; and

- the NEB *Filing Manual* (NEB 2013a).

Subsequent steps of an effects assessment include a cumulative effects assessment (Section 8.0), inspection and monitoring during construction and post-construction (Volume 6A) and follow-up monitoring (Section 10.0).

An ESA Approach Summary document was released to stakeholders, Aboriginal communities and potentially interested regulatory authorities in March 2013 by Trans Mountain. The intent of the document was to provide an overview of Trans Mountain's understanding of the environmental and socio-economic context of the Project at that time. The methods, indicators and spatial boundaries for the environmental elements were reviewed based on feedback received on the ESA Approach Summary document from participants of the ESA Workshops, consultation with regulatory authorities and engagement with Aboriginal communities.

The environmental effects assessment of the Project is a collaborative effort of several qualified professionals with element-specific expertise, under the guidance of representatives of TERA. Table 7.1-1 acknowledges the contribution of these experts and professionals by environmental element.

TABLE 7.1-1

ENVIRONMENTAL EFFECTS ASSESSMENT TEAM

Environmental Element	Assessor
Physical and Meteorological Environment	TERA and BGC
Soil and Soil Productivity	TERA and Mentiga
Water Quality and Quantity	Waterline and TERA
Air Emissions	RWDI
GHG Emissions	RWDI
Acoustic Environment	RWDI
Fish and Fish Habitat	GeoMarine and TERA
Wetland Loss or Alteration	TERA
Vegetation	TERA
Marine Sediment and Water Quality	Stantec
Marine Fish and Fish Habitat	Stantec
Wildlife and Wildlife Habitat	TERA
Marine Mammals	Stantec
Marine Birds	Stantec
Species at Risk	TERA and Stantec
Accidents and Malfunctions	TERA
Changes to the Project Caused by the Environment	TERA

7.1.1 Environmental Elements

The potential environmental (*i.e.*, biophysical) elements interacting with the Project have been identified through: consultation and engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public; experience gained during previous pipeline projects with similar conditions/potential issues (*e.g.,* TMX Anchor Loop Project, Trans Mountain Pump Station Expansion Project, Blue River Pump Station Project); scientific studies; and the professional judgment of the assessment team. Issues noted during consultation/engagement with Aboriginal communities, landowners, federal, provincial and municipal regulatory authorities, stakeholders and the general public were essential in the determination of element interactions with the Project (Section 3.0).

Environmental elements potentially interacting with the Project include:

- physical elements such as the physical and meteorological environment, soil and soil productivity, water quality and quantity, air emissions, GHG emissions and the acoustic environment;

- biological elements such as fish and fish habitat, wetland loss or alteration, vegetation, wildlife and wildlife habitat, and species at risk; and

- marine elements such as marine sediment and water quality, marine fish and fish habitat, marine mammals, marine birds and marine species at risk.

Effects arising from potential accidents and malfunctions, and changes to the Project caused by the environment are also considered. The assessment of onshore facility hypothetical spill scenarios, including a spill at the Westridge Marine Terminal, on the environment is provided in Volume 7.

Those environmental elements which are not considered to interact with the Project are identified and discussed in Sections 7.2 to 7.7. In accordance with Guide A.2.6 of the NEB *Filing Manual*, no further analysis is necessary for those elements where interactions between the Project component and an environmental element are not predicted.

7.1.2 Assessment Indicators and Measurement Endpoints

Beanlands and Duinker (1983) suggest that it is impossible for an impact assessment to address all potential environmental effects of a project. Therefore, it is necessary that the environmental attributes considered to be important in project decisions be identified. Environmental impact assessments should be required to identify at the beginning of the assessment an initial set of indicators (sometimes called Valued Ecosystem Components [VECs] or Valued Social Components [VSCs]) to provide a focus for subsequent study and evaluation (Beanlands and Duinker 1983).

For this assessment, an indicator is defined as a biophysical, social or economic property or variable that society considers to be important and is assessed to predict Project-related changes and focus the impact assessment on key issues. One or more indicators are selected to describe the present and predicted future condition of an element. Societal views are understood by the assessment team through published information such as management plans and engagement with regulators, the public, Aboriginal communities and other interested groups.

The indicators for each element have been identified based on: the NEB *Filing Manual* and other regulatory guidelines; experience gained during previous projects with similar conditions/potential issues; feedback from Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public; public issues raised through media; available research literature; and professional judgment of the assessment team.

One or more 'measurement endpoints' (measurable parameters) are identified for each indicator to allow quantitative or qualitative measurement of potential Project effects. The endpoints have been selected based on: the NEB *Filing Manual*; experience gained through during previous projects with similar conditions/potential issues; feedback from regulatory authorities and stakeholders; available research literature; and professional judgment of the assessment team. The degree of change in these measurable parameters is used to characterize and evaluate the magnitude of Project-related effects. A selection of measurement endpoints may also be the focus of monitoring and follow-up programs, where applicable.

7.1.3 Spatial and Temporal Boundaries

The environmental effects assessment considers the potential effects of the Project on the environment in the context of defined spatial and temporal boundaries. These boundaries vary with the issues and environmental elements or interactions to be considered, and reflect:

- the construction, operations, and decommissioning and abandonment phases of the proposed physical works and physical activities;

- the natural variation of a population or environmental indicator;

- the timing of sensitive life cycle phases of various biotic elements in relation to the scheduling of the proposed physical works and physical activities;

- the time required for an effect to become evident;

- the time required for a population or environmental indicator to recover from an effect and return to a natural condition;
- the area directly affected by proposed physical works and physical activities; and
- the area in which a population or environmental indicator functions and within which a Project effect may be experienced.

Temporal Boundaries

The time frames of the assessment of the Project include the planning, construction (including reactivation/modification), operations, and decommissioning and abandonment phases. The planning phase includes all environmental studies, engineering surveys and land surveys conducted in support of the Project application and prior to construction. The construction phase for the TMEP includes surveying, clearing, soil handling, grading, pipeline trenching and testing, construction at the Westridge Marine Terminal, facility assembly or expansion, additional tankage at Edmonton, Sumas and Burnaby Terminals, pipeline reactivation, pump station reactivation and reclamation.

Pending regulatory approval of the Project, construction of the pipeline and facilities is scheduled over an approximately 24 month period to achieve the planned in-service date of late 2017. The installation of automated valves would occur intermittently from Q2 2016 to Q1 2017, while the reactivation of existing pipeline segments would occur from Q3 2016 to Q4 2017. Construction and equipment installation at pump stations and tank terminals is expected to begin in Q1 2016 and take approximately 8 to 10 months for each pump station and between 14 and 23 months at the terminals, depending on, among other variables, scope, land use and construction techniques for each facility. The construction period at the Westridge Marine Terminal is expected to commence in Q4 2015 with the first berth expected to be in-service by Q3 2017. The second and third new berths are expected to be in-service by late 2017. Demolition of the existing berth is planned to commence in late 2017 after the new berths are commissioned. The operations phase commences following completion of construction in Q4 2017 and is anticipated to extend for 50 years or more. The decommissioning and abandonment phase would occur at the end of the useful life of the pipeline (50 to 70 years). A detailed construction schedule for the Project is provided in Section 2.0.

Spatial Boundaries

The assessment of the Project was undertaken in the context of one or more of the following spatial boundaries: the Footprint; Local Study Area (LSA); Regional Study Area (RSA); Provincial Area; National Area; and International Area. LSAs and RSAs were developed on an element-specific basis and, therefore, may vary between environmental elements. The Footprint of the Project assumes certain quantitative values for the area that will be directly disturbed by Project facilities and activities within the proposed pipeline corridor, including: a 45 m pipeline construction right-of-way (assumed conservative average value including permanent easement and temporary workspace); permanent access road at Black Pines Pump Station (assumed 5 m wide x 25 m long); temporary access roads (assumed to use existing access, where practical); camp and stockpile sites (assumed 7 ha averaging one every 80 km on existing disturbance); valves (assumed to be within the disturbed right-of-way); and power lines (assumed 50 m wide).

The definitions for each spatial boundary are provided in Table 7.1-2. Detailed discussions regarding the element-specific LSAs, RSAs and associated rationale are provided in Sections 7.2 to 7.7.

Individually established ecological boundaries are described within the discussions in Sections 7.2 to 7.7 for each applicable biological element. Spatial ecological boundaries were determined by the distribution, movement patterns and potential zones of interaction between an element and the Project. The ecological boundary may be limited to the Footprint (*e.g.,* proposed pipeline construction right-of-way) or extend beyond the physical boundaries of the area of the Project component since the distribution or movement of an element can be local, regional or provincial, national or international in extent.

7.1.4 *Potential Environmental Effects*

The potential environmental effects resulting from the Project are identified through engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public; through experience gained during previous pipeline projects with similar conditions/potential issues; through scientific studies; and the professional judgment of the assessment team. The potential environmental effects arising from the construction and operations of the pipeline, temporary facilities, pump stations, tanks and the expansion of the Westridge Marine Terminal, as well as the reactivation of existing pipeline segments and the installation of automated valves, are identified in Sections 7.2 to 7.7. Section 7.8 discusses potential effects of decommissioning and abandonment.

This assessment is based on preliminary engineering and designs. In general, conservative assumptions have been used. In order to confirm the predictions on environmental effects, further technical development will be carried out in the engineering and detailed design phase.

TABLE 7.1-2

EVALUATION OF THE SIGNIFICANCE OF RESIDUAL EFFECTS - ENVIRONMENTAL ASSESSMENT CRITERIA[1]

Assessment Criteria		Definition
IMPACT BALANCE – of the Residual Effect		
Positive		Residual effect is considered to have a net benefit to the environmental indicator.
Neutral		Residual effect is considered to have no net benefit or loss to the environmental indicator.
Negative		Residual effect is considered to be a net loss or a detriment to the environmental indicator.
SPATIAL BOUNDARY – Location of Residual Effect		
Footprint		The area directly disturbed by surveying, construction and clean-up of the pipeline and associated physical works and activities (including, where appropriate, the permanent right-of-way, pump stations, tanks, Westridge Marine Terminal, temporary construction workspace, temporary stockpile sites, temporary staging sites, construction camps, access roads, power lines).
LSA		The zone of influence (ZOI) or area where the element and associated indicators are most likely to be affected by Project construction and operations. This generally represents a buffer from the centre of the proposed pipeline corridor or edge of a facility site.
RSA		The area extending beyond the LSA boundary where the direct and indirect influence of other activities could overlap with Project-specific effects and cause cumulative effects on the environmental indicator. This varies for each element.
Provincial		The area extending beyond regional or administrative boundaries but confined to AB and BC (*e.g.,* provincial permitting boundaries).
National		The area extending beyond AB and BC but confined to Canada.
International		The area extending beyond Canada.
TEMPORAL CONTEXT		
Duration – (period of the event causing the effect)	Immediate	Event is limited to less than or equal to two days during either the construction phase or operations phase.
	Short-term	Event occurs during the construction phase or is completed within any 1 year during the operations phase.
	Long-term	Ongoing event that is initiated during the construction phase and extends beyond the first year of the operations phase or is initiated during the operations phase and extends for the life of the Project.
Frequency[2] - (how often would the event that caused the effect occur)	Accidental	Event occurs rarely over assessment period.
	Isolated	Event is confined to a specified phase of the assessment period.
	Occasional	Event occurs intermittently and sporadically over the assessment period.
	Periodic	Event occurs intermittently but repeatedly over the assessment period.
	Continuous	Event occurs continually over the assessment period.
Reversibility (period of time over which the residual effect extends)	Immediate	Residual effect is alleviated in less than or equal to two days.
	Short-term	Greater than two days and less than or equal to 1 year to reverse residual effect.
	Medium-term	Greater than 1 year and less than or equal to 10 years to reverse residual effect.
	Long-term	Greater than 10 years to reverse residual effects.
	Permanent	Residual effects are irreversible.
MAGNITUDE[3] – of the Residual Environmental Effect		
Negligible		Residual effects are not detectable from existing (baseline) conditions.
Low		Residual effects are detectable, but well within environmental and/or regulatory standards.
Medium		Residual effects are detectable and may approach, but are still within the environmental and/or regulatory standards.
High		Residual effects are beyond environmental and/or regulatory standards.
PROBABILITY OF OCCURRENCE – Likelihood of Residual Effect		
High		Likely

TABLE 7.1-2 Cont'd

Assessment Criteria	Definition
Low	Unlikely
LEVEL OF CONFIDENCE[4] – Degree of Certainty Related to Significance Evaluation	
Low	Determination of significance based on incomplete understanding of cause-effect relationships and incomplete data pertinent to the Project area.
Moderate	Determination of significance based on good understanding of cause-effect relationships using data from outside the Project area or incompletely understood cause-effect relationships using data pertinent to the Project area.
High	Determination of significance based on good understanding of cause-effect relationships and data pertinent to the Project area.

Notes: 1 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

2 The assessment period for the effects assessment includes planning, construction, operations, and decommissioning and abandonment phases for the Project while the assessment period for the cumulative effects assessment includes the above interval as well as the development, construction and operations phases of activities or projects that have previously occurred and those that are planned (publicly disclosed).

3 In consideration of magnitude, there is no environmental standard, threshold, guideline or objective for many of the construction/operations issues under evaluation. Therefore, the determination of magnitude of the adverse residual effect often entailed a historical consideration of the assessment of magnitude made by regulators, land authorities, lessees, other stakeholders and the assessment team to adverse effects. The assessment team was also aware of the increasingly stringent societal norms related to environmental effects.

4 Level of confidence was affected by availability of data, precedence and degree of scientific uncertainty or other factors beyond the control of the assessment team.

7.1.5 Mitigation Measures

Mitigation measures, as defined under the *CEA Act, 2012*, means measures for the elimination, reduction or control of a project's adverse environmental effects, including restitution for any damage to the environment caused by such effects through replacement, restoration, compensation or any other means.

To ensure that the potential adverse environmental effects are reduced, general and site-specific mitigation measures are recommended in this ESA based upon current industry-accepted standards, consultation with regulatory authorities, interested groups and individuals, engagement with Aboriginal communities, and the professional judgment of the assessment team. Mitigation measures, suggested by regulatory authorities or other stakeholders have been incorporated into this assessment.

Many of the mitigation measures presented in this ESA have been discussed with Aboriginal communities that have been involved in specific supporting environmental studies. A comprehensive review of all the issues that have been raised by each community and the recommended mitigation measures was conducted with each community during the field surveys and during follow-up results review (Section 3.0).

Mitigation measures are outlined in the Project effects assessment, as well as in the Project-specific Environmental Protection Plans (EPPs) (Volumes 6B through 6D). Mitigation measures in element-specific technical reports are incorporated into the assessment. In addition, various federal and provincial regulatory authorities, and industry-accepted standards and guidelines are considered in the ESA, and are referenced for each element.

Accompanying this ESA are Environmental Alignment Sheets (Volume 6E) which identify where some site-specific mitigation measures are to be implemented. Inspector(s) will be retained by Trans Mountain to help ensure that the mitigation measures within this ESA are understood and properly implemented during construction. Environmental inspection is further described in Volume 6A.

7.1.6 Residual Effects

As defined in the NEB *Filing Manual* (NEB 2013a), residual effects are the environmental effects that are present after mitigation measures are applied. In many situations, the mitigation measures are predicted to eliminate the potential adverse effects while in other situations, the mitigation measures are predicted to lessen the effects, but do not entirely eliminate them. Elements for which no residual effects are predicted require no further analysis (*i.e.*, significance evaluation).

7.1.7 Significance Evaluation of Potential Residual Effects

The determination of the significance of potential residual effects generally followed the guidelines and principles provided by the NEB, CEA Agency and FEARO documents listed in Section 7.1. The agencies identify several possible methods for determining whether residual environmental effects are significant. These include:

- the use of regulatory environmental standards, guidelines or objectives in relation to potential residual effects;
- quantitative assessment of residual effects; and
- qualitative assessment of residual effects.

The NEB *Filing Manual* indicates that the quantitative method should be used where possible; otherwise, the qualitative method can be used. Some elements can be assessed quantitatively using regulatory standards and guidelines. Where there are no standards, guidelines, objectives or other established and accepted thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method that is based on available literature is considered to be the appropriate method for determining the significance of most of the potential residual effects. Consequently, the significance is evaluated by developing a set of qualitative criteria based on those identified by Hegmann *et al.* (1999). These criteria are identified below and their definitions are presented in Table 7.1-2.

- Spatial boundary (*i.e.*, the geographic extent in the Footprint, LSA, RSA, Provincial, National, International).
- Temporal context (*i.e.*, duration and frequency of the event causing the residual effect, reversibility of the residual effect).
- Magnitude (*i.e.*, severity of the residual effect in relation to environmental and/or regulatory standards).
- Probability or likelihood of occurrence of the residual effect.
- Level of confidence or uncertainty (*i.e.*, availability of data to substantiate the assessment conclusion, previous success of mitigation measures).

The ecological context (*e.g.,* levels of existing disturbance; resilience of the receiving environment) is not included in Table 7.1-2. However, the ecological context is provided in Section 7.2 for each applicable element.

For environmental elements, a significant residual effect has a high probability of occurrence, is permanent or reversible in the long-term, is of high magnitude and cannot be technically or economically mitigated.

The impact balance or direction (*i.e.*, determination as to whether the effect is positive, neutral or negative) was also established for each predicted environmental residual effect. A positive impact balance is considered to have a net benefit to the environmental indicator. A neutral impact balance is defined as having no net benefit or loss to the environmental indicator. A negative balance is considered to be a net loss or detriment to the environmental indicator.

All significance assessment criteria (*e.g.,* temporal context, magnitude) are considered by the assessment team for each residual environmental effect. Where appropriate, the key or most influential assessment criteria used to determine the significance of each residual effect are noted. It should be noted that the determination of a “not significant residual effect” is based on a pre-defined approach that incorporates magnitude, probability and reversibility, but a “not significant residual effect” determination does not mean that the potential residual effect is not important to one or more Aboriginal communities, landowners, regulatory authorities or stakeholders.

For the Project effects assessment, an evaluation of combined residual effects is conducted for those indicators where more than one identified potential adverse residual effect may occur. The evaluation of the combined effects considers only those residual effects that are likely to occur (*i.e.*, of high probability). A discussion of combined effects is included in the significance evaluation in Section 7.11 to clarify the overall effect of the Project on the environmental indicator in question and the overall effect of the Project on the element. In addition, the overall effects of the Project on the element are evaluated in consideration of the objectives or goals of applicable land and resource use management plans, municipal development plans (MDPs) and government policies.

The extent to which the professional judgment of the assessment team is used to evaluate the significance of potential environmental residual effects is provided within the relevant section of the assessment for each element. For this Project, the assessment team consisted of discipline experts, the TERA Project Manager, experienced assessment practitioners and senior reviewers. For some elements, the evaluation of significance benefited from a review of select publically available post-construction environmental monitoring reports from previous Trans Mountain projects and other projects that encountered environmental settings and associated issues similar to those of the Project.

A summary of the significance evaluation for predicted residual environmental effects arising from the construction and operations of the proposed pipeline, temporary facilities, pump stations (including reactivation of a station), tanks, the expansion of the Westridge Marine Terminal and reactivation of existing pipeline segments is provided in Sections 7.2 to 7.7. A discussion of effects for decommissioning and abandonment is provided in Section 7.8. A summary of the significance evaluation for residual effects arising from accidents and malfunctions is provided in Section 7.9.

7.2 Effects Assessment - Pipeline Construction and Operations

Using the assessment methodology described in Section 7.1, the potential environmental effects associated with the construction and operations of the pipeline component of the Project as well as the proposed mitigation measures and resulting residual effects on the environmental indicators were evaluated for each element and are described in the following subsections. In addition, the evaluation of significance of potential residual effects using the criteria presented in Table 7.1-2 is also provided. A discussion of the potential effects associated with decommissioning and abandonment of the pipeline is provided in Section 7.8.

Environmental elements potentially interacting with construction and operations of the proposed pipeline segments are identified in Table 7.2-1.

TABLE 7.2-1

ELEMENT INTERACTION WITH THE PROPOSED PIPELINE COMPONENT

Element	Interaction with Pipeline Component	
	Construction	Operations[1]
Physical and Meteorological Environment	Yes	Yes
Soil and Soil Productivity	Yes	Yes
Water Quality and Quantity	Yes	Yes
Air Emissions	Yes	Yes
GHG Emissions	Yes	Yes
Acoustic Environment	Yes	Yes
Fish and Fish Habitat	Yes	Yes
Wetland Loss or Alteration	Yes	Yes
Vegetation	Yes	Yes
Wildlife and Wildlife Habitat	Yes	Yes
Species at Risk	Yes	Yes

Note: 1 Activities during operations include aerial and ground patrols, vegetation management and integrity digs.

7.2.1 Physical and Meteorological Environment

This subsection describes the potential Project effects on physical environment. Further information pertaining to the physical environment along the proposed pipeline corridor is provided in the following reports prepared by BGC Engineering Inc.: Route Physiography and Hydrology, Terrain Mapping and Geohazard Inventory, and Seismic Assessment Desktop Study of Volume 4A; and the Acid Rock Drainage and Metal Leaching Potential Technical Report of Volume 5C. Section 7.10 provides an assessment of changes to the Project caused by the environment.

7.2.1.1 Assessment Indicators and Measurement Endpoints

Assessment indicators identified for the physical environment element are: terrain instability; topography; and acid generating and metal leaching rock. Assessment indicators and measurement endpoints for physical environment are listed in Table 7.2.1-1. Potential effects related to the meteorological environment are considered under Section 7.10 Changes to the Project Caused by the Environment.

The selection of indicators for physical and meteorological environment included: consideration of the filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues; feedback from Aboriginal communities, regulatory authorities and stakeholders; available research literature; public issues raised through the media; and the professional judgment of the assessment team. A list of the proposed physical environment indicators was discussed during the ESA Workshops. An additional physical environment indicator suggested by participants was karst topography in the Lower Mainland. A response to this stakeholder recommendation is provided in Section 7.2.1.4. Participants of the workshops did not indicate that the proposed physical environment indicators were inappropriate for evaluating the effects of the Project on physical and meteorological environment.

Qualitative measurement endpoints are applied to assess potential Project effects on physical environment indicators (Table 7.2.1-1).

TABLE 7.2.1-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR PHYSICAL ENVIRONMENT

Physical Environment Indicators	Measurement Endpoints	Rationale for Indicator Selection
Terrain instability	• Areas of steep slopes • Areas susceptible to slumping at watercourses • Areas of sidehills	The selection of indicators and measurement endpoints considered NEB *Filing Manual* requirements for the physical and meteorological environment element in Table A-2, addressed concerns raised through stakeholder engagement and were informed by regulatory authorities (*i.e.*, AESRD and BC MFLNRO).
Topography	• Areas of steep slopes • Areas of sidehills • Areas susceptible to blasting	
Acid generating and metal leaching rock	• Areas susceptible to acid generating rock and/or metal leaching	

7.2.1.2 Spatial Boundaries

The spatial boundaries used in the effects assessment of physical environment considered one or more of the following areas:

- a Footprint Study Area (as defined in Section 7.1.3); and
- a Physical Environment LSA.

A Physical Environment LSA was established to reflect the area in which Project construction and operations activities would be most likely affect the physical environment. The Physical Environment LSA is defined as the ZOI likely to be affected by terrain instability during construction and operations of the proposed pipeline, consisting of a 1 km wide band generally extending from the centre of the proposed pipeline corridor and facilities (*i.e.*, 500 m on both sides of the proposed pipeline corridor centre) to incorporate effects that may extend off the Footprint (*e.g.,* blasting, water erosion on slopes, slumping, acid rock drainage [ARD]). Potential effects are not anticipated to extend beyond the Physical Environment LSA and, therefore, a Physical Environment RSA has not been established.

The Physical Environment LSA was discussed during the ESA Workshops held in March 2013. There was general agreement that the Physical Environment LSA boundary was appropriate and no alternative boundaries were suggested for consideration by the assessment team.

The study area boundaries for the Physical Environment LSA have been used to define the spatial boundary for the Soil LSA based on the extent of the effects of both of these environmental elements. Further details regarding the Soil LSA are provided in Section 7.2.2.2.

7.2.1.3 Physical Environment Context

The proposed pipeline corridor along the Edmonton to Hinton Segment crosses the following physiographic regions: Eastern Alberta Plains; Western Alberta Plains; Southern Alberta Uplands; and Rocky Mountains physiographic regions (Pettapiece 1986). The proposed pipeline corridor in BC crosses the following physiographic regions: Rocky Mountains, Rocky Mountain Trench, Columbia Mountains and Interior Plateau physiographic regions along the Hargreaves to Darfield Segment; Interior Plateau and Cascade Mountains physiographic regions along the Black Pines to Hope Segment; and the Cascade Mountains and Georgia Depression physiographic regions along the Hope to Burnaby and Burnaby to Westridge Segments (Holland 1976). No permafrost is expected to be encountered along the proposed pipeline corridor (refer to Section 5.1.1 for additional information) and no active volcanoes are located in vicinity to the proposed pipeline corridor.

BGC Engineering Inc. investigated and characterized the potential for acid rock drainage (ARD) and metal leaching along the proposed pipeline corridor (refer to the Acid Rock Drainage and Metal Leaching Potential Technical Report of Volume 5C). Of the sites investigated during the field program, nine were considered to contain potentially acid generating (PAG) material. Of these nine sites, three were classified as PAG along the proposed pipeline corridor in the Physical Environment LSA:

- Site 004 is located along the Edmonton to Hinton Segment at RK 14. The ARD potential at this site is considered to be high due to the modest sulphide-S content associated with the coal fragments within the till. There is very little neutralization potential available within the till to neutralize any acid that may be generated from the coal seams.

- Site 019 is located along the Hargreaves to Darfield Segment at RK 669.5. The ARD potential at this site is considered to be high due to the high sulphide-S content. Given the low neutralization potential of the surrounding material, it is uncertain if the non-PAG rock will have the potential to neutralize all the acid generated from the PAG material.

- Site 042 is located along the Black Pines to Hope Segment at RK 987.8. This site had the highest total-sulphur content of all the samples, but measured sulphide content was low, as was the leachable sulphate content. Consequently, ARD potential at this site is considered to be moderate since total sulphur is dominated by non-extractable sulphur and not a likely a concern (*i.e.*, the risk of ARD is minimal).

No traditional ecological knowledge (TEK) was collected for any physical environment indicators and participants did not share any specific information or concerns with respect to terrain instability, topography, or acid generating and metal leaching rock.

7.2.1.4 Potential Effects and Mitigation Measures

<u>Effects Considerations</u>

The topic of naturally occurring radioactive materials (NORMs) was raised during public consultation activities and whether there are any potential effects associated with the Project. NORMs are long-lived radioactive elements of the Earth's crust normally found in low concentrations, although higher concentrations can result from human activities (Health Canada 2000). In the oil and gas industry, NORMs may be encountered in liquids and gases from hydrocarbon-bearing geological formations, contaminated soils, liberated shale deposits and accumulations of slurry debris (Health Canada 2000, Jaremko 2006). Trans Mountain considers exposure to NORMs as a very low risk for the current Project and, consequently, any potential effects associated with the presence of NORMs were not carried through the assessment.

During the Surrey ESA Workshop, a participant noted the possible presence of karst in the area of the proposed pipeline corridor and questioned whether there would be any potential effects associated with constructing on karst lands. However, the only area where karst lands have been documented in the Lower Mainland is in the mountains southeast of the City of Chilliwack, well outside of the Physical Environment LSA (Pike *et al.* 2010). Consequently, any potential effects associated with karst lands were not carried through the assessment.

Identified Potential Effects

Potential effects associated with the construction and operations of the proposed pipeline on physical environment indicators are listed in Table 7.2.1-2. These interactions are based on the results of the literature review, desktop analysis, field work, engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.2.1-2 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines including Alberta Environment (AENV) (1994a,b, 1995), BC Oil and Gas Commission (OGC) (2013), BC Ministry of Energy and Mines (Price and Errington 1998) and Government of Alberta (2001, 2013a).

TABLE 7.2.1-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON PHYSICAL ENVIRONMENT

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Physical Environment Indicator – Terrain Instability				
1.1 General Measures	All	LSA	• Blast bedrock encountered within trench depth only if ripping or typical trenching methods are not feasible [Section 8.3]. See additional blasting measures in Section 8.3 of the Pipeline EPP. • Assess the need for special trench compaction measures or equipment prior to commencement of backfilling [Section 8.4]. See additional backfilling measures in Section 8.4 of the Pipeline EPP. • Install subsoil cross ditches and berms on steep and moderate slopes on tame pasture, and treed lands in order to prevent runoff along the construction right-of-way and subsequent erosion [Section 8.6]. • Recontour the construction right-of-way, including the removal of temporary subsoil berms on agricultural land and re-establish the pre-construction grades and drainage channels if frozen soil conditions prevented completion of this task during backfilling [Section 8.6]. • Confirm, prior to seeding/planting, that surface texturing is present on steep slopes. If warranted, establish mounds to create microsites on steep, wind exposed slopes where woody vegetation establishment is desirable to retain moisture and enhance vegetation establishment success by creating mounds on steep slopes or, where grass vegetation establishment is desirable, implement track cleat imprinting by aligning the final pass of bulldozers parallel to the slope during the final pass [Section 8.6]. • Revegetate as soon as feasible to reduce or avoid soil erosion and establish long-term cover. Seed immediately following topsoil/root zone material replacement [Section 8.6]. See additional erosion control and revegetation measures in Section 8.6 of the Pipeline EPP.	• Areas of terrain instability may occur as a result of construction activities.

TABLE 7.2.1-2 Cont'd

Potential Effect	Pipeline Segments	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.2 Terrain instability due to slumping at watercourse crossings	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	LSA	• Install the pipeline at each watercourse using the technique as identified in environmental resource-specific mitigation table for aquatic resources in Appendix I of Volume 6B and as shown on the Environmental Alignment Sheets in Volume 6E. Ensure that the technique is implemented as per the reports/notifications/applications provided to applicable regulators [Section 8.7]. • Bore the irrigation canal crossings during the irrigation season or where a trenched crossing will result in potentially long-term bank instability [Section 8.3]. • Take extra care to compact the trench at banks of watercourse crossings that have been trenched [Section 8.4]. Stabilize and revegetate areas disturbed during installation and removal of a bridge; install erosion control measures, where warranted, to control surface erosion until vegetation is established [Section 8.7]. • Return the bed and banks of each watercourse crossing as close as feasible to their pre-construction contours (slope and height). Take appropriate measures to reduce the risk of sloughing of the streambanks following construction [Section 8.7]. • Install riprap bank armouring [see Streambank Protection – Cobble or Riprap Armouring Drawing in Appendix R] along unstable banks with high erosion potential locations [Section 8.7]. • Install permanent erosion control measures, as outlined in the Reclamation Management Plan [Appendix C] unless otherwise approved by Trans Mountain to adjust for site conditions and suitability [Section 8.6]. • Seed riparian areas with an approved annual or perennial grass cover crop or native grass mix as soon as feasible after construction [Section 8.6]. See additional erosion control and revegetation measures in Section 8.6 of the Pipeline EPP.	• Areas of slope instability may occur if trenched crossing methods are required at large watercourse crossings.
1.3 Terrain instability due to sidehill terrain	All	LSA	• Replace grade material to a stable contour that will approximate the pre-construction contour, except where it is not practical or safe to do so [Section 8.4].	• Areas of terrain instability may occur as a result of construction activities.
2. Physical Environment Indicator – Topography				
2.1 Alteration of topography along steep slopes	All	LSA	• Minimize grading on steep slopes, unless safety concerns are identified [Section 8.2]. • Install subsoil cross ditches and berms on steep and moderate slopes on tame pasture, and treed lands in order to prevent runoff along the construction right-of-way and subsequent erosion [Section 8.6]. • Recontour the construction right-of-way, including the removal of temporary subsoil berms on agricultural land and re-establish the pre-construction grades and drainage channels if frozen soil conditions prevented completion of this task during backfilling [Section 8.6]. • Regrade areas with vehicle ruts, erosion gullies or where the trench has settled [Section 8.6]. • Rollback slash and small diameter, salvageable timber on steep slopes [Section 8.6]. • Apply hydromulch/hydroseed at a rate recommended by the supplier on steep recontoured slopes [Section 8.6]. • Confirm, prior to seeding/planting, that surface texturing is present on steep slopes. If warranted, establish mounds to create microsites on steep, wind exposed slopes where woody vegetation establishment is desirable to retain moisture and enhance vegetation establishment success by creating mounds on steep slopes or, where grass vegetation establishment is desirable, implement track cleat imprinting by aligning the final pass of bulldozers parallel to the slope during the final pass [Section 8.6].	• Topography may be altered at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability.

TABLE 7.2.1-2 Cont'd

Potential Effect	Pipeline Segments	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.2 Alteration of topography along slopes of watercourse crossings	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	LSA	• Restrict root grubbing to the area located outside of the vegetated riparian buffer adjacent to watercourses [Section 8.1]. See additional root grubbing measures in Section 8.1 of the Pipeline EPP. • Fell trees away from watercourses and away from limits of the construction right-of-way to reduce damage to streambanks, beds and adjacent trees [Section 8.1]. • Reduce grading along the construction right-of-way and associated facilities, especially within watercourse and wetland vegetated buffers and on hay land and tame pasture lands with a competent vegetation mat/sod layer [Section 8.2]. • Confine the use of fords to watercourses or segments of watercourses with low, stable banks and a stable substrate composed of materials such as gravel or bedrock. Trans Mountain will not grade the banks to create a ford. Install matting, where warranted, to protect the bed and banks of a watercourse to be forded [Section 8.7]. • Re-establish streambanks and approaches immediately following construction of water crossings as outlined in the Reclamation Management Plan [Appendix C] [Section 8.6]. • Recontour the construction right-of-way and stabilize approach slopes at watercourse crossings. Where reclamation of the pre-construction grade is not feasible due to risk of failure of fill on slopes or maintenance of an access trail, recontour to grades as directed by the Geotechnical Engineer [Section 8.6].	• Topography may be altered at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability.
2.3 Alteration of topography due to sidehill terrain	All	LSA	• Replace grade material to a stable contour that will approximate the pre-construction contour, except where it is not practical or safe to do so [Section 8.4].	• Topography may be altered at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability.
2.4 Alteration of topography at areas of blasting	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	LSA	• Blast bedrock encountered within trench depth only if ripping or typical trenching methods are not feasible [Section 8.3]. • Dispose of excess blast rock and excavated rock at approved locations [Section 8.3]. • Dispose of excess rock displaced from the trench or from blasting on non-agricultural lands in discrete piles, windrows or scattered along the construction right-of-way, or as directed by the landowner or appropriate regulatory authority [Section 8.6].	• Topography may be altered at locations where blasting occurs.
3. Physical Environment Indicator – Acid Generating and Metal Leaching Rock				
3.1 Acid generation or metal leaching rock	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope	LSA	• Adhere to recommendations of the Soil/Geotechnical Resource Specialist and/or the Lead Environmental Inspector and Inspector(s) at locations where ARD may be present and trench dewatering is necessary. Record locations and estimated volumes of trench water discharged [Section 8.3]. • Adhere to recommendations in the Acid Rock Drainage and Metal Leaching Potential Technical Report (Volume 5C).	• Acidification/ contamination of the terrestrial and/or aquatic environment from ARD or metal leaching.

Notes: 1 LSA = Physical Environment LSA.

2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.2.1.5 Potential Residual Effects

The potential residual environmental effects on physical environment indicators associated with the construction and operations of the pipeline (Table 7.2.1-2) are:

- areas of terrain instability may occur as a result of construction activities;
- areas of slope instability may occur if trenched crossing methods are required at large watercourse crossings;
- topography may be altered at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability;
- topography may be altered at locations where blasting occurs; and
- acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching.

7.2.1.6 Significance Evaluation of Potential Residual Effects

Where there are no standards, guidelines, objectives or other established and accepted ecological thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method is considered to be the appropriate method for determining the significance of the anticipated residual environmental effects. Consequently, a qualitative assessment of physical environment was determined to be the most appropriate method with the evaluation of significance of each of the potential residual effects relying on the professional judgment of the assessment team.

Table 7.2.1-3 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the proposed pipeline on the physical environment. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.1-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON PHYSICAL ENVIRONMENT

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Physical Environment Indicator – Terrain Instability									
1(a)	Areas of terrain instability may occur as a result of construction activities.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant
1(b)	Areas of slope instability may occur if trenched crossing methods are required at large watercourse crossings.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low	Low	High	Not significant
2.	Physical Environment Indicator – Topography									
2(a)	Topography may be altered at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability.	Negative	LSA	Short-term	Isolated	Permanent	Low to medium	High	High	Not significant
2(b)	Topography may be altered at locations where blasting occurs.	Negative	LSA	Short-term	Isolated	Permanent	Low	High	High	Not significant
2(c)	Combined effects on the topography indicator (2[a] and 2[b]).	Negative	LSA	Short-term	Isolated	Permanent	Low to medium	High	High	Not significant
3.	Physical Environment Indicator – Acid Generating and Metal Leaching Rock									
3(a)	Acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low	Low	High	Not significant

Notes: 1 LSA = Physical Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Physical Environment Indicator – Terrain Instability

The following provides the evaluation of significance of potential residual effects on the terrain instability indicator.

Terrain Instability

Terrain instability resulting from construction of the Project was a concern identified during several of the stakeholder engagement events for the Project (*e.g.,* Hope, Abbotsford, Coquitlam and Burnaby Community Workshops). Minor areas of terrain instability may occur along areas of the proposed pipeline corridor as a result of the proposed construction activities (*e.g.,* grading, trenching, blasting and backfilling). The impact balance of this residual effect is considered negative since terrain instability could affect the safety of the pipe and result in surface erosion. Terrain along most of the proposed pipeline corridor is considered to be stable, based on observations and operating experience of the existing TMPL system to date, as well as the results of the Terrain Mapping and Geohazard Inventory (Volume 4A). The proposed pipeline corridor does, however, cross several mountain ranges and encounters adverse topography and angled bedrock with the potential to cause slope failure and rock slide events during construction activities. Some notably steep areas along the proposed pipeline corridor are located in the North Thompson River valley, near the District of Hope, in the Coquihalla River valley and at Sumas Mountain.

During construction of the TMX Anchor Loop Project, minor rock slides occasionally resulted during blasting activities at three locations, which were readily cleaned up, and a debris (rock and soil) slide occurred along a steep slope north of the trench line. Although material from the debris slide was cleaned up, it resulted in a scar extending approximately 10 m beyond the right-of-way boundaries. No other issues related to terrain instability were encountered during construction (TERA 2009a).

Selection of the proposed pipeline corridor for the new segments considered reducing exposure to known locations of slope instability, potential for rock falls and debris flows, and reducing potential of construction and long-term operations of the pipeline to effect stability of the surrounding terrain. These terrain stability considerations along with their standard mitigation measures are summarized in Section 4.1 of Volume 4A. The entire proposed pipeline corridor has been evaluated for terrain stability by qualified engineering consultants and the results are provided in the Terrain Mapping and Geohazard Inventory (Volume 4A). The KMC Natural Hazards Management Program database for the existing TMPL system was also used as a source to identify specific areas of concern.

During construction of the pipeline, removal of vegetation and root mass, grading, blasting, cut and fills and runoff controls could lead to localized areas of potential instability. Monitoring during construction will ensure any observed instability issues will be resolved early before potentially severe instability problems arise. Grade material will be replaced to a stable contour that will approximate the pre-construction contour, except where it is not practical or safe from a pipe integrity perspective or for public safety. When replacing sidehills or other graded areas is not practical due to the risk of slope failure, the Inspector(s), Construction Manager and a geotechnical engineer will discuss to determine an appropriate grade.

During pipeline construction, there is potential for Project construction to trigger large slide or rock fall events (*e.g.,* steep terrain in the Coquihalla River valley). Risks associated with specific areas of potential instability will be characterized during the geotechnical risk assessment for the Project; planned to commence as part of detailed engineering design. Specific mitigation or contingency measures, including minor reroutes, if warranted, will be implemented if deemed necessary to avoid high risk areas. Furthermore, during grading of the new right-of-way, the potential for localized instability and rock fall concerns will be identified. In these instances, qualified geotechnical engineers will review the locations of concern and, where warranted, prepare site-specific mitigation designs.

During operations, prior to establishment of a vegetative cover, exposed slopes and cut and fills prone to instability have the potential to become unstable as a result of increased pore pressure (from water saturated soil) and erosion (*e.g.,* sloughing from gullying and scouring). During post-construction environmental monitoring for the TMX Anchor Loop Project in 2010, erosion gullies were observed at several locations along the pipeline right-of-way. Site-specific sediment and erosion control measures were implemented the same year to provide effective long-term stability (TERA 2011a). During post-construction environmental monitoring in 2012, only one erosion gully was observed, and repaired, along the right-of-way (TERA 2013a). Sink holes also have the potential to occur from subsurface erosion along the pipeline trench during operations. During post-construction environmental monitoring for the TMX Anchor Loop Project in 2009, sinkholes were observed at six locations along the right-of-way (TERA 2009b). Remedial measures were conducted during the summer of 2009 and during subsequent years, no new sink holes were identified and the reclaimed sink holes were observed to be stable. Other than a small, localized slumping event, no other issues related to terrain instability were observed during post-construction environmental monitoring for the TMX Anchor Loop Project (TERA 2009b, 2011a, 2013a).

Regular aerial and ground patrols will be conducted to examine vegetation establishment and confirm mitigation measures are functioning as intended, as well as identify any new areas of potential instability. At any areas where a mass wasting event is observed, appropriate measures will be implement to clean-up and stabilize the site. Monitoring of the reclaimed sites will continue until the site is determined to be in a stable condition.

Effective route refinement prior to construction will help to reduce the overall effect of the Project along areas of steep and potentially unstable topography. Furthermore, the construction of the pipeline will comply with industry accepted practices and measures outlined in the Pipeline EPP (Volume 6B) as well as engineering and design considerations in Volume 4A and, therefore, the pipeline is not expected to cause rock slides, slumping or other mass wasting events. The mitigation measures in Table 7.2.1-2 have been found to be effective during construction and reclamation of the TMX Anchor Loop Project. Similar mitigation measures are planned for the construction of the proposed pipeline. Areas of potential terrain instability will be regularly monitored during aerial patrols over the life of the pipeline and promptly remediated, where necessary, to protect pipeline integrity and reduce effects on the environment. The residual effect of terrain instability occurring as a result of planned construction activity is reversible in the short to medium-term and of low magnitude (Table 7.2.1-3, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Physical Environment LSA - terrain instability as a result of construction activities may extend beyond the construction workspace.
- Duration: short-term – the event causing potential terrain instability is construction of the pipeline (*e.g.,* grading, and rough clean-up).
- Frequency: isolated – the event causing potential terrain instability (*i.e.*, construction of the pipeline) is confined to a specific period.
- Reversibility: short to medium-term – most areas of terrain instability will be remediated within a year, however, some areas may require a second or third year of remedial effort to fully stabilize.
- Magnitude: low – the implementation of the proposed mitigation measures in addition to detailed engineering design is expected to effectively reduce the severity and extent of potential effects on terrain instability.
- Probability: high – terrain instability is likely to result from pipeline construction at localized areas.
- Confidence: high – based on data pertinent to the Project area and the experience of the assessment team.

Slope Instability at Watercourses

Areas of slope instability may occur where a trenched crossing method is used at watercourse crossings. The impact balance of this residual effect is considered negative since slope instability could affect the safety of the pipe and water quality of the watercourses. Terrain along the proposed pipeline corridor ranges from level to undulating to mountainous, with steep slopes present at many of the larger and intermediate watercourses. The placement of trenchless crossing entry and exit locations well back from the potentially unstable areas and the depth of the drill path are expected to avoid the effect of terrain instability issues on the pipeline. However, where a trenchless crossing is unsuccessful or not feasible and a trenched (*i.e.*, isolated if water present/open cut if dry or frozen to the bottom) installation is necessary, Trans Mountain will engage a geotechnical engineer regarding additional mitigation measures to prevent and control terrain instability, as needed, during construction. The installation of erosion protection measures will reduce the potential for slumping occurrence. Specific mitigation measures will be embedded in detailed crossing drawings that will be developed during detailed engineering design to address site-specific slope stability issues at watercourses. The residual effect of slope instability during trenched watercourse crossings is of low magnitude and is reversible in the short to medium-term depending on the length of time required to restabilize the affected area (Table 7.2.1-3, point 1[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Physical Environment LSA – slope instability as a result of trenching at watercourses may extend beyond the construction workspace.
- Duration: short-term – the event causing potential slope instability is construction of the pipeline (*e.g.,* grading, trenching and backfilling during trenched crossing).
- Frequency: isolated – the event causing potential slope instability (*i.e.*, construction of the pipeline) is confined to a specific period.
- Reversibility: short to medium-term – depending upon the length of time required to restabilize the affected area.
- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the potential effects on slope instability.
- Probability: low – slope instability will likely be avoided by the installation of erosion protection measures and proper trenched crossing procedures.
- Confidence: high – based on the professional experience of the assessment team on previous pipeline projects with similar conditions.

Combined Effects on Terrain Instability

An evaluation of the combined effects considers those residual effects that may interact with each other and are likely to occur. Since terrain instability occurring during construction and operations activities is the only likely potential residual effect identified, an evaluation of combined effects of the pipeline on the terrain instability indicator is not warranted.

Physical Environment Indicator – Topography

The following provides the evaluation of significance of potential residual effects on the topography indicator.

Alteration of Topography at Cut Slopes

As a result of construction, topography along the proposed pipeline corridor may be altered at locations where cut slopes are too steep to be returned to the pre-construction profile. Alteration of topography was raised as concern at Kamloops and Merritt Community Workshops, specifically along grassland areas between the proposed Black Pines Pump Station and the existing Kingsvale Pump Station.

Grading of the construction right-of-way must be sufficient to accommodate pipe stringing, welding, field bending, lowering-in and safe movement of pipe, equipment and personnel along the construction right-of-way. Grading along the construction right-of-way will vary from only topsoil/root zone material salvaging in some areas to extensive cuts and fills in other areas. The grade and trench rock along the construction right-of-way will be ripped mechanically using bulldozers and excavators, where practical. Otherwise, controlled blasting techniques in will be used (refer to Alteration of Topography from Blasting below). Following construction, the construction right-of-way, including approach slopes at watercourse crossings, will be recontoured to pre-construction profiles and stabilized, except where it is not practical or safe to do so.

Alteration of topography will be reduced by installing the pipeline adjacent to the existing TMPL right-of-way and other linear infrastructure (*e.g.,* Telus fibre optic line right-of-way, Spectra gas pipeline right-of-way). In grassland areas around the cities of Kamloops and Merritt, the proposed pipeline corridor will parallel the existing TMPL right-of-way for most of its length. The impact balance of this residual effect is considered negative since local topographic alteration is considered a detriment to the environment. Although this unavoidable consequence will be permanent in localized areas and of high probability, the magnitude is considered to be low to medium depending on the extent of topographic alteration, type of vegetative cover (*e.g.*, treed vs. grassland) and sensitivity of nearby receptors (Table 7.2.1-3, point 2[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Physical Environment LSA – alteration of topography may extend beyond the construction workspace.
- Duration: short-term – the event causing the potential alteration of topography is construction of the pipeline.
- Frequency: isolated – the event causing the potential alteration of topography (*i.e.*, construction of the pipeline) is confined to a specific period.
- Reversibility: permanent – alteration of topography resulting from slopes that are too steep to be restored to the pre-construction profile cannot be reversed.
- Magnitude: low to medium – the implementation of the proposed mitigation measures is expected to effectively reduce the potential effect of alteration of local topography, however, grassland areas where bedrock is likely to be encountered between the proposed Black Pines Pump Station and the existing Kingsvale Pump Station are particularly susceptible to visible alterations in topography.
- Probability: high – the proposed pipeline corridor encounters areas of steep terrain where it is likely that cut slopes may not be returned to pre-construction profiles.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Alteration of Topography from Blasting

Blasting of the trench and grade rock is expected to be required only after all reasonable means of excavation by mechanical equipment (*e.g.,* bulldozers, excavators) have been used and are unsuccessful in achieving the required results, and where deemed absolutely necessary by construction and blasting experts after detailed site examination. The impact balance of this residual effect is considered negative since local topographic alteration is considered a detriment to the environment. This unavoidable consequence will be permanent and of high probability. However, efforts will be made to reduce the area of permanent disturbance by ensuring blasting will only be conducted by licensed blasters and implementing controlled blasting techniques in accordance with Trans Mountain's Blasting Specification for grade and trench rock excavation. The Blasting Specification will be developed during detailed engineering design for the Project.

Detonation methods and procedures will be dependent on, among other factors, associated rock type and geological structure (solid, layered, or fractured). On occasion, control over the volume and extent of material removed may be limited due to difficulties in predicting extent and accuracy of blast parameters and indeterminate geologic structures and nearby terrain instabilities. Test blasting will be conducted at locations where blasting is required to evaluate ground damage and vibration and establish site-specific blasting parameters and procedures to reduce unintentional disturbances and potential instabilities.

On occasion, unintended alterations in topography may occur resulting from mass wasting events triggered during blasting. For example, during construction of the TMX Anchor Loop Project, a debris (rock and soil) slide occurred along a steep slope north of the trench line resulting in a scar extending approximately 10 m beyond the right-of-way boundaries (TERA 2009a). Otherwise, no issues related to shallow bedrock or blasting were encountered during construction (TERA 2009a). To limit any unintended alterations in topography, a Blasting Management Plan will be prepared prior to construction to ensure blasting is performed in a manner that safeguards the public and environment, and alterations of terrain are controlled and limited to the required site dimensions for safe construction and pipeline installation. Given the anticipated limited extent of blasting along the construction right-of-way (*i.e.*, only in areas where excavation by mechanical equipment is unsuccessful), implementation of mitigation measures, and since most blasting will be conducted in remote areas well away from receptors and/or adjacent to terrain previously altered from existing linear infrastructure, magnitude is considered to be low (Table 7.2.1-3, point [2b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Physical Environment LSA – alteration of topography from blasting may extend beyond the construction workspace.
- Duration: short-term – the event causing the potential alteration of topography from blasting is construction of the pipeline.
- Frequency: isolated – the event causing the potential alteration of topography from blasting (*i.e.*, construction of the pipeline) is confined to a specific period.
- Reversibility: permanent – topography altered from blasting activities is unlikely to be restored to the pre-construction profile and cannot be reversed.
- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the potential effect of alteration of topography from blasting.
- Probability: high – there are localized areas along the proposed pipeline corridor where blasting activities will likely be necessary.
- Confidence: high - based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on Topography

An evaluation of the combined effects considers those likely residual effects which contribute to overall effects on topography. Therefore, both residual effects evaluated in Table 7.1.3-3 (points 2[a] and 2[b]) could act in combination on the topography indicator.

The adverse effects identified have the potential to contribute to combined effects on topography along the proposed pipeline corridor. This residual effect is considered permanent and the probability of these residual effects acting in combination to alter topography at any specific location along the proposed pipeline corridor is high. The magnitude of the combined effects on the topography indicator is considered to be low to medium since the combined effect is likely to be reduced by implementation of mitigation strategies for each of the residual effects and since most of proposed pipeline corridor parallels the existing TMPL right-of-way and/or other linear infrastructure (Table 7.2.1-3, point 2[c]). A summary of the rationale for all of the significance criteria of combined effects on the topography indicator is provided below.

- Spatial Boundary: Physical Environment LSA – combined effects on the topography indicator may extend beyond the construction workspace.
- Duration: short-term – the event causing the combined effects on the topography indicator is construction of the pipeline.
- Frequency: isolated – the event causing the combined effects on the topography indicator (*i.e.*, construction of the pipeline) is confined to a specific period.
- Reversibility: permanent – combined effects on the topography indicator may result in alterations of topography which cannot be restored to pre-construction conditions.
- Magnitude: low to medium – combined effects on the topography indicator are anticipated to be largely mitigated during construction.
- Probability: high – it is likely that topography will be altered at cut slopes where pre-construction contours cannot be replaced and at areas where blasting occurs.

- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Physical Environment Indicator – Acid Generating and Metal Leaching Rock

The following provides the evaluation of significance of potential residual effects on the acid generating and metal leaching rock indicator.

Acid Rock Drainage and Metal Leaching

Although no specific concerns were identified during stakeholder engagement events, participants in the Clearwater and Kamloops Community Workshops were unfamiliar with ARD and questioned how it will be mitigated.

Exposing, excavating or reusing rock during construction can increase the likelihood of ARD from sulphide-bearing rocks due to increased interaction with water and oxygen and larger surface areas relative to undisturbed rock. Processes that could disturb bedrock during pipeline construction include grading by cutting or filling, and trenching, which will expose bedrock in the walls of the trench. Weathering conditions, such as those related to the oxidation of metal sulphides (*e.g.,* pyrite) will largely determine if ARD will be generated by the exposed outcrops identified as potentially containing acid generating (PAG) materials. Geochemical conditions (*e.g.,* pH, alkalinity) created by weathering play a major role in determining trace element solubility and, therefore, the potential for offsite dissolved metal transport. An important factor controlling the rates and timing of metal release and leaching is whether or not ARD will occur and, if so, the timing of the onset of ARD. The impact balance of this residual effect is considered negative since ARD and metal leaching is considered a detriment to the environment.

Effectively managing ARD along the pipeline construction right-of-way will reduce the environmental effects and the need for remediation. Site conditions that need to be taken into consideration in order to properly mitigate PAG and metal leaching areas include location, topography, climate, geology, hydrology and hydrogeology, availability of neutralizing materials, and vegetation. Climate variations along the proposed pipeline corridor are considerable; therefore, physical weathering processes such as expansion and contraction of the rock due to freeze/thaw events should be taken into consideration. Furthermore, chemical weathering processes continue at temperatures below 0ºC. The ionic strength (*e.g.,* salinity) of the pore water may depress the freezing point of water which could result in unfrozen water present in waste materials at temperatures well below freezing.

Exposure of PAG material to oxygen and water will be kept to a minimum during pipeline construction. As recommended in the Acid Rock Drainage and Metal Leaching Potential Technical Report (Volume 5C), this will be achieved by reducing the time of exposure, reducing excess PAG material generated by grading and trenching, and by covering freshly exposed PAG material with a compacted cover of till or clay material in a way that promotes water shedding while limiting potential erosion. Any PAG material will be stored at sites that are elevated and dry to avoid exposure to any surface or groundwater flow. In the event long-term storage of PAG material is required, a thick vegetation mat (*e.g.,* grass) should be maintained on the cover. Any excess rock that will not be returned to the construction right-of-way and reclaimed will be removed from the site as per recommendations of the Soil/Geotechnical Resource Specialist and/or the Lead Environmental Inspector and Inspector(s).

Given the mitigation measures, the likelihood of acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching rock during or after construction of the pipeline is considered to be low. The magnitude of this residual effect is considered to be low as well based on the material composition of identified PAG sites and the limited volume of materials being disturbed and exposed from construction (Table 7.2.1-3, point 3[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Physical Environment LSA – any ARD or metal leaching may extend beyond the construction workspace.

- Duration: short-term – short-term ARD or metal leaching may result from exposure of fresh rock-cut surfaces during construction until mitigation measures are implemented (*e.g.*, covering fresh surfaces, proper storage) or material is removed from site and properly disposed of.

- Frequency: isolated – ARD or metal leaching may be confined to exposed construction materials until covered or removed from site.
- Reversibility: short to medium-term – acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching may result in localized changes to the surrounding environment, which may take longer than 1 year to fully remediate.
- Magnitude: low – given implementation of the proposed mitigation measures to effectively reduce the potential effect and based on the material composition of identified PAG sites and the limited volume of materials being disturbed and exposed from construction.
- Probability: low – given implementation of the proposed mitigation measures to effectively reduce the potential effect and given the limited volume of materials being disturbed and exposed from construction.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

7.2.1.7 Summary

As identified in Table 7.2.1-3, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the physical environment indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline construction and operations on the physical environment will be not significant.

7.2.2 Soil and Soil Productivity

This subsection describes the potential Project effects on soil and soil productivity. The Soils Technical Report of Volume 5C provides further information pertaining to existing soil conditions along the proposed pipeline corridor.

7.2.2.1 Assessment Indicators and Measurement Endpoints

Assessment indicators identified for the soil and soil productivity element are: soil productivity; soil degradation; bedrock and stone disposal; and soil contamination. Assessment indicators and measurement endpoints for soil and soil productivity are listed in Table 7.2.2-1.

The selection of indicators for soil and soil productivity included: consideration of the filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues; feedback from Aboriginal communities and stakeholders; feedback from participants in ESA Workshops; available research literature; public issues raised through the media; and the professional judgment of the assessment team. A list of the proposed indicators for soil and soil productivity were discussed during the Edmonton, Kamloops and Surrey ESA Workshops held in March 2013. The proposed indicators were also discussed with participants of an agricultural-focused ESA Workshop in Abbotsford in May 2013. Participants of the workshops did not indicate that the proposed soil indicators were inappropriate for evaluating the effects of the Project on soil and soil productivity.

Food production was suggested as an additional indicator by a participant of the Surrey ESA Workshop. Upon consideration by the assessment team, food production was not adopted as a soil indicator since this topic is discussed as part of the indicator of agricultural use in Section 7.2.4 Human Occupancy and Resource Use of Volume 5B. Food production is also discussed in the Agricultural Assessment Technical Report of Volume 5D.

Qualitative measurement endpoints are applied to assess potential Project effects on soil and soil productivity indicators. Table 7.2.2-1 provides a summary of the indicators and measurement endpoints used in the assessment of potential effects on soil and soil productivity.

TABLE 7.2.2-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR SOIL AND SOIL PRODUCTIVITY

Soil Indicators	Measurement Endpoints	Rationale for Indicator Selection
Soil productivity	• Areas susceptible to topsoil/root zone material and subsoil mixing • Areas susceptible to saline lower subsoil mixing with upper horizons • Changes in evaporation and transpiration rates • Areas of shallow bedrock • Hydrostatic test water discharge locations • Areas susceptible to trench subsidence • Areas susceptible to clubroot infestation	The selection of indicators and measurement endpoints considered NEB *Filing Manual* requirements for soil and soil productivity element in Table A-2 and addressed concerns raised through Aboriginal engagement and stakeholder consultation.
Soil degradation	• Areas susceptible to compaction and rutting • Areas susceptible to wind erosion • Areas susceptible to water erosion • Areas susceptible to surface water erosion on slopes • Areas susceptible to pulverization of soil and sod • Hydrostatic test water discharge locations	
Bedrock and stone disposal	• Areas of shallow bedrock or stony soils	
Soil contamination	• Identification of historic contaminated sites • Hydrostatic test water discharge locations • Possible future contamination	

7.2.2.2 Spatial Boundaries

The spatial boundaries used in the effects assessment of soil and soil productivity considered one or more of the following areas:

- a Footprint Study Area (as defined in Section 7.1.3); and
- a Soil LSA.

A Soil LSA was established to reflect the area in which Project construction and operations activities would be most likely to affect soil and soil productivity. The ZOI likely to be affected by direct disturbance is defined as a 1 km wide band generally extending from the centre of the proposed pipeline corridor and facilities (*i.e.*, 500 m on both sides of the proposed pipeline corridor centre) to incorporate effects that may extend off the Footprint (*e.g.,* wind/water erosion). Potential effects are not anticipated to extend beyond the Soil LSA and, therefore, an RSA for soil and soil productivity was not established.

The Soil LSA was discussed during the ESA Workshops held in March 2013 and during the agricultural-focused ESA Workshop held in Abbotsford in May 2013 (Section 3.0). There was general agreement that the Soil LSA boundary was appropriate, although a suggestion was made to go beyond 1 km for select agricultural areas in the Lower Mainland. Upon consideration, the assessment team felt that for the types of potential effects on soil and soil productivity likely to result from the construction and operations of the pipeline, a 1 km LSA was deemed appropriate.

7.2.2.3 Soil Context

The Edmonton to Hinton Segment is located primarily in an agricultural area and encounters mainly previously disturbed soils. Chernozems and Luvisols are the dominant soil orders encountered along this segment of the proposed pipeline corridor (Natural Regions Committee 2006). The proposed pipeline corridor in BC encounters mountainous, rural, urban and agricultural areas. Luvisols and Podzols are the dominant soil orders encountered along the segments of the proposed pipeline corridor in BC (Valentine *et al.* 1978).

A soil survey was conducted on lands with agricultural capability for new pipeline segments along the proposed pipeline corridor approximately every 250 m on ALR lands or wherever there was a change in the crop being grown or topography encountered (see Soils Technical Report of Volume 5C). A variety of surficial deposits occur along the proposed pipeline corridor. Topography along the proposed pipeline corridor is varied. Steeper slopes are generally confined to larger watercourse crossings and mountainous areas. In total, 186 soil units were described and mapped along the proposed pipeline corridor. Bedrock within trench depth may be encountered in certain soil units; however, it is anticipated that most bedrock can be easily excavated using normal trenching procedures. Locations of soil types encountered along the proposed pipeline corridor are identified on the Environmental Alignment Sheets (Volume 6E).

Known occurrences of clubroot have been identified in Alberta and BC. Generally, the risk of clubroot disease is higher along the eastern portion of the proposed pipeline corridor (*e.g.,* Parkland County and Yellowhead County) and in the Lower Mainland (*e.g.,* FVRD).

Historical spills have occurred along the existing TMPL right-of-way. To address the releases, various remedial methods were employed to the standards of the time. The locations of historical spills will be monitored during construction for signs of contamination. If contamination is suspected, the Contamination Discovery Contingency Plan (Appendix B of the Pipeline EPP of Volume 6B) will be implemented.

A cursory inventory of potential third-party contaminated sites was conducted by reviewing aerial photography to identify potential sites which could be sources of contamination that have the potential to affect the proposed pipeline corridor. Areas of interest were identified within the proposed pipeline corridor and will be monitored during construction.

No Crown dispositions related to soil conservation were identified as being crossed by the proposed pipeline corridor in Alberta or BC (Alberta Energy 2013, BC ILMB 2013).

7.2.2.4 Potential Effects and Mitigation Measures

Effects Considerations

Participants at the Abbotsford and Surrey ESA Workshops expressed concern over heat generated from the pipeline affecting soils. Previous studies of the effects of pipeline temperature on soil and crop growth have been conducted for the TransCanada Pipeline, LP (TransCanada) Keystone XL Pipeline Project and the Alliance Pipeline Project. These studies suggest that effects on surficial soil temperature attributable to an operating pipeline are negligible, and that the heating of rooting zone soil by the pipeline did not have a statistically significant effect on plant available soil water (Dunn *et al.* 2004, TransCanada 2009). Further discussion on soil temperature near the pipe and limited potential to affect crop growth are provided in the Agricultural Assessment Technical Report of Volume 5D and under the agricultural use indicator of Section 7.2.4 Human Occupancy and Resource Use of Volume 5B.

Participants at the Abbotsford and Chilliwack Community Workshops expressed concern that there is naturally occurring asbestos in the soil in the areas around Abbotsford (particularly the former Sumas Lake bed) and Chilliwack. Asbestos-containing sediment is found in the Sumas River originating from a landslide in the 1930s on the Swift Creek tributary in Washington State. The landslide is composed of serpentine rock which is rich in asbestos and heavy metals. The portion of the Sumas River flowing through the Abbotsford area has been contained within its channel by a diking system built in the 1920s and there has been no overbanking in any areas near the existing TMPL right-of-way. The risk of disturbing asbestos rich soils in the Abbotsford area is extremely low since no sediment from the Sumas River has been deposited on farmland since the time of the landslide (McTavish pers. comm.). Consequently, asbestos in the soil was not carried through the assessment. The Sumas River was dredged in the early 1980s and sediments containing asbestos are stored on the river bank and capped to prevent any exposure. Any sediment from recent dredging has been deposited in a secure landfill, eliminating any risk of exposure to asbestos (McTavish pers. comm.). Trans Mountain is aware of the location of the stored dredged sediments on the banks of the Sumas River.

Identified Potential Effects

Potential effects associated with the construction and operations of the proposed pipeline on soil and soil productivity indicators are listed in Table 7.2.2-2. These interactions are based on the results of the literature review, desktop analysis, field work, Aboriginal engagement, consultation with landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.2.2-2 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines including AENV (1988, 1994a,b, 1995, 1998), Alberta Pipeline Environmental Steering Committee (1996), BC OGC (2010a) and Canadian Association of Petroleum Producers (CAPP) (1996, 1999, 2008).

TABLE 7.2.2-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON SOIL AND SOIL PRODUCTIVITY

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Soil Indicator – Soil Productivity				
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging	All	Footprint	<u>Topsoil/Root Zone Material Depth</u> • Salvage all available topsoil (min. 10 cm and max. 40 cm) and root zone material (min. 15-20 cm or 50% organic material and 50% mineral soil) using the Environmental Alignment Sheets as a guide [Section 8.2]. • Utilize three-lift soils handling where indicated on the Environmental Alignment Sheets (see Drawings [Topsoil or Root Zone Material Salvage – Three-Lift Soils Handling on Well-Sodded Land] and [Topsoil or Root Zone Material Salvage – Three-Lift Soils Handling on Cultivated Land] provided in Appendix R) [Section 8.2]. • Overstrip topsoils to a total depth indicated on the Environmental Alignment Sheets at select locations with saline or sodic lower subsoils, or sands and gravels at depth which occurs on native grassland, irrigated lands and/or areas of high wind erosion (see Environmental Alignment Sheets) [Section 8.2]. • Salvage surface material in unsaturated wetlands, giving extra attention to maintaining dormant root stocks for replacement, where feasible. Salvage a maximum of 40 cm of surface soil if the peat is deeper than 40 cm or to the depth of colour change where there is less than 40 cm of surface material. Ensure a minimum of 15 cm of surface and subsoil is stripped if peat is less than 15 cm [Section 8.2]. • Salvage very shallow surface soils (*i.e.*, organic and mineral soils) to at least a 15 cm depth, unless the material is unsuitable (*e.g.,* bedrock, gravel, rock) [Section 8.2]. • See additional measures in Section 8.2 of the Pipeline EPP. <u>Topsoil/Root Zone Material Salvage (General)</u> • Implement the Wet/Thawed Soils Contingency Plan (see Appendix B) during wet/thawed soil conditions in the event wet or thawed soils are encountered during construction [Section 8.2]. • Accommodate landowner/Crown land authority topsoil/root zone material salvage requests, if feasible. Record any locations where a landowner/land authority has requested topsoils handling which differs from the planned method [Section 8.2]. • Maintain a separation distance between the topsoil and the upper subsoil piles as well as between upper and lower subsoil piles, where three-lift soils handling is conducted [Section 8.3].	• Mixing of topsoil/root zone material and subsoil.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging (cont'd)	All	Footprint	• Salvage topsoil/root zone material from areas to be graded and windrow to the closest edge of the construction right-of-way. Avoid overstripping. The area salvaged is to correspond to the area to be graded [Section 8.2]. See additional grading measures in Section 8.2 of the Pipeline EPP. • Store topsoil/root zone material prior to grading along the nearest pipeline construction right-of-way boundary taking into consideration space requirements for grade and trench spoil, existing nearby hotlines, local topography and drainage [Section 8.2]. • Keep trench spoil pile separate from topsoil/root zone material pile. Maintain a minimum separation distance of 1 m between topsoil and trench spoil piles (on agricultural lands (see Drawing [Conventional Right-of-Way Configuration] provided in Appendix R) [Section 8.3]. Topsoil/Root Zone Material Salvage (Non-frozen) • Salvage topsoil/root zone material from the entire construction right-of-way (see Drawing [Topsoil or Root Zone Material Salvage in Forest – Full Right-of-Way] provided in Appendix R) where grading is necessary and at locations indicated on the Environmental Alignment Sheets [Section 8.2]. • Salvage topsoil from the entire construction right-of-way at locations indicated on the Environmental Alignment Sheets (as outlined in the Line List) where localized weed infestations are encountered or at organic farm locations (see Drawing [Topsoil Salvage in Agricultural Lands – Full Right-of-Way] provided in Appendix R) [Section 8.2]. • Salvage topsoil from the trench and spoil pile area (see Drawing [Topsoil or Root Zone Material Salvage – Trench and Spoil Area] provided in Appendix R) at the locations indicated on the Environmental Alignment Sheets [Section 8.2]. • Salvage a blade width of topsoil/root zone material centered over the trench (see Drawing [Topsoil or Root Zone Material Salvage – Blade Width/Frozen] provided in Appendix R) at locations indicated on the Environmental Alignment Sheets. Disc well-sodded lands prior to topsoil/root zone material salvage in order to facilitate topsoil salvage operations [Section 8.2]. • Salvage topsoil from twice the width of the trench centred over the trench at locations indicated on the Environmental Alignment Sheets [Section 8.2]. • See additional topsoil/root zone material salvage measures in Section 8.2 of the Pipeline EPP. Topsoil/Root Zone Material Salvage (Frozen) • Pre-salvage topsoil/root zone material prior to freeze-up if feasible. Attempt to have all topsoil/root zone material salvage completed prior to October 31 where feasible for areas to be constructed that winter in Alberta and Interior BC [Section 8.2]. • Salvage topsoil/root zone material from an area approximately 1 m wider than the trench and centred over the trench (see Drawing [Topsoil or Root Zone Material Salvage – Trench Width] provided in Appendix R) a t all locations during frozen soil conditions unless otherwise indicated on the Environmental Alignment Sheets [Section 8.2]. See additional measures in Section 8.2 of the Pipeline EPP.	• See above.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging (cont'd)	All	Footprint	• During winter construction, avoid mixing snow with spoil material during backfill. Have trench spoil backfilled by the end of the working day to minimize hazards to livestock and wildlife, as well as reduce frost penetration. Ensure that all segments trenched during frozen soil conditions are backfilled prior to spring breakup [Section 8.4]. • Postpone compaction of frozen trench spoil until final clean-up in mid to late spring [Section 8.4]. <u>Topsoil/Root Zone Material Replacement</u> • Follow mitigation measures for backfilling as outlined in Section 8.4 of the Pipeline EPP. • Postpone replacement during wet conditions or high winds to prevent damage to soil structure or erosion of topsoil/root zone material [Section 8.6]. • Replace topsoil/root zone material evenly over all portions of the construction right-of-way that have been stripped. Salvage a wider area of topsoil, if warranted, on cultivated, hay or tame pasture lands where topsoil salvage was conducted during the winter to allow excess trench spoil to be feathered-out over the stripped area (see Drawing [Conventional Right-of-Way Configuration] provided in Appendix R) [Section 8.6]. • Revegetate as soon as feasible to reduce or avoid soil erosion and establish long-term cover. Seed immediately following topsoil/root zone material replacement [Section 8.6]. • See additional topsoil/root zone material replacement mitigation measures in Section 8.6 of the Pipeline EPP.	• See above.
1.2 Decreased topsoil/root zone material productivity through trench instability during trenching	Edmonton to Hinton (Alberta) Elk Point, Peace Hills, Primula, Rochester, peaty Rochester, shallow Rochester, Sundance BC Pipeline Segments 46 soil units (see Soils Technical Report of Volume 5C)	Footprint	• Suspend trenching and salvage a wider area of topsoil/root zone material if the trench walls slough into the trench and the potential for topsoil/root zone material/subsoil mixing exists. Backslope the trench walls until stable. Equip backhoe with a swamp bucket, if practical, to avoid or reduce trench sloughing [Section 8.3]. • Weld up pipe prior to trenching at locations with soils prone to sloughing in order to reduce the time the trench is left open [Section 8.3]. • Limit the length of open trench and the time the trench will be left open to reduce the amount of trench sloughing, frost penetration and interference with wildlife, landowners and livestock [Section 8.3]. • Store salvaged topsoil or root zone material at a sufficient distance from the trench so that topsoil or root zone material is not lost in the trench, if trench instability is anticipated [Section 8.3]. • Delay trenching until immediately prior to lowering-in at locations with a high water table or where there is a risk of sloughing [Section 8.3].	• Mixing of topsoil/root zone material and subsoil due to trench instability.
1.3 Decreased topsoil/root zone material productivity through mixing due to shallow topsoil/root zone material	Edmonton to Hinton (Alberta) gleyed Alluvium, shallow Bremay, stony Cooking Lake, Devon 1, Devon 2, Hoadley, shallow Hubalta, Modeste, MacKay, peaty Onoway, peaty Rochester, Sundance, Wildwood, peaty Wildwood BC Pipeline Segments 77 soil units (see Soils Technical Report of Volume 5C)	Footprint	• Overstrip topsoils to a total depth indicated on the Environmental Alignment Sheets at select locations with saline or sodic lower subsoils, or sands and gravels at depth which occurs on native grassland, irrigated lands and/or areas of high wind erosion (see Environmental Alignment Sheets) [Section 8.2].	• Mixing of topsoil/root zone material and subsoil due to shallow topsoil/root zone material depths.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.4 Decreased topsoil productivity through mixing due to poor colour change	Edmonton to Hinton (Alberta) Bremay, Cooking Lake, Evansburg, Hubalta, shallow Hubalta, Modeste, MacKay, peaty MacKay, Maywood, Primula, Rosevear, Sundance BC Pipeline Segments Chasm, Flat Creek, gleyed Nicholson, Glossey 1, Glossey 2, Isar, Lundbom, Lonzo Creek, Minnie, Scat, shallow Flat Creek, saline Flat Creek, shallow Courtney, Ryder, shallow Tranquille, Tranquille, Whatcom	Footprint	• Where soils are not readily distinguishable by colour, the Inspector(s) will provide direction based on an evaluation of soil texture and structure as well as the recommended depths noted on the Environmental Alignment Sheets [Section 8.2]. • Clearly identify the topsoil piles and grade spoil piles with signs or staking where the topsoil/subsoil colour change is not obvious [Section 8.2].	• Mixing of topsoil/root zone material and subsoil due to poor colour change between topsoil/root zone material and subsoil.
1.5 Decreased soil productivity through mixing with gravely lower subsoils	BC Pipeline Segments Carvolth 1, Dixon, Fairfield 1, Hopedale, Struthers 2 overlying gravel, Struthers 3, Sim	Footprint	• Utilize three-lift soils handling where indicated on the Environmental Alignment Sheets (see Drawings [Topsoil or Root Zone Material Salvage – Three-Lift Soils Handling on Well-Sodded Land] and [Topsoil or Root Zone Material Salvage – Three-Lift Soils Handling on Cultivated Land] provided in Appendix R). Salvage topsoil from the trench and spoil area on lands requiring three-lift soils handling. Depths of material to be removed during the upper subsoil lift will be outlined on the Environmental Alignment Sheets unless otherwise directed by the Inspector(s) [Section 8.2]. • Maintain a separation distance between the topsoil and the upper subsoil piles as well as between upper and lower subsoil piles, where three-lift soils handling is conducted [Section 8.3]. • Ensure that the lower lift of subsoil is backfilled before the upper lift of subsoil where three-lift soils handling has been conducted [Section 8.4].	• Undesirable lower subsoils may be unexpectedly encountered and admixed with upper subsoil horizons.
1.6 Decreased soil productivity resulting from changes in evaporation and transpiration rates	All	Footprint	• Implement mitigation measures provided in point 2.1 of this table to reduce compaction and rutting of soils along the construction right-of-way. • Implement mitigation measures provided in points 2.2 and 2.3 of this table to reduce loss of topsoil/root zone material through wind erosion and water erosion, respectively. • Use only Certified Canada No. 1 or the best available agronomic seed. For native seed, the highest seed grade available will be obtained [Section 8.6]. • Follow seeding and revegetation measures outlined in Section 8.6 of the Pipeline EPP.	• Reduction in soil productivity on agricultural areas resulting from changes in evaporation and transpiration rates.
1.7 Decreased soil productivity from use of sand as bedding material	All	Footprint	• Avoid depositing bedding or padding material on non-salvaged topsoil/root zone material prior to placement in the trench unless a snow layer is present or is otherwise approved by the Inspector(s) [Section 8.4].	• No residual effect identified.
1.8 Decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land	All	LSA	• Implement mitigation measures provided in potential effect 2.6 of this table to prevent/reduce erosion of soil as a result of release of hydrostatic test water on land. • Implement mitigation measures provided in potential effect 4.2 of this table to prevent/reduce contamination of soil as a result of release of hydrostatic test water on land.	• No residual effect identified.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.9 Decreased soil productivity from disturbance (*e.g.,* maintenance dig activities) during operations	All	Footprint	• Implement the recommended soil handling procedures outlined in the Pipeline EPP to reduce the potential for a reduction in soil productivity when construction activities involving soil disturbance are necessary during operations of the pipeline. • Monitor areas along the construction right-of-way that are disturbed during operations and maintenance activities. Implement remedial measures, where warranted.	• Mixing of topsoil/root zone material and subsoil.
1.10 Decreased soil productivity from trench subsidence	All	Footprint	• Compact the backfill, if feasible, to reduce trench settlement by running a grader wheel over the backfill when the trench has been backfilled to the level of the surrounding ground. Take extra care to compact the trench at banks of watercourse crossings and wetlands that have been trenched [Section 8.4]. • Crown the trench with remaining spoil to allow for settlement. A larger crown will be needed to compensate for settlement after thawing allows the portion of the route constructed during frozen soil conditions [Section 8.4]. • Postpone feathering-out of excess spoil along segments of the route constructed during frozen soil conditions until after the spring breakup and the trench has settled [Section 8.4]. • Feather-out excess trench spoil over the salvaged portion of the construction right-of-way on a non-peat land use during non-frozen soil conditions to avoid the creation of a permanent trench crown. Excess spoil will not be feathered-out over the salvaged area to an extent that may cause excessive subsidence of the trench [Section 8.4]. • Leave a trench crown during clean-up of peatlands and non-peat wetlands to allow for settlement of backfilled material within the trench [Section 8.6]. • See additional measures in Section 8.4 of the Pipeline EPP.	• Excessive trench subsidence or a remnant crown.
1.11 Decreased soil productivity from soil diseases (*i.e.,* clubroot disease and potato cyst nematodes)	All	LSA	• All equipment will be fine cleaned and disinfected prior to mobilization to the construction right-of-way [Section 2.1 of Appendix C]. • Follow phased sanitation approach as presented in the *Alberta Clubroot Management Plan*, CAPP *Best Management Practices for Clubroot Disease*, and the Canadian Food Inspection Agency *Best Management Practices for Preventing Potato Cyst Nematode Contamination* [Section 2.1 of Appendix C]. • When travelling on foot, remove excess topsoil from footwear and any equipment (*e.g.,* shovels) before moving between cultivated quarter-sections. When working in high risk areas or when requested by the landowner, this may include wearing disposable booties [Section 2.1 of Appendix C]. • Work and traffic on topsoil will be minimized between quarter-sections and during wet conditions, to the extent feasible. Extra caution will be taken regarding topsoil transfer on slightly wet soil and working in very wet soil conditions will be avoided, where possible [Section 2.1 of Appendix C]. • During construction activities, equipment involved in clearing/brushing and topsoil handling will be cleaned at designated cleaning stations, either with compressed air or with a power wash plus disinfectant misting. Cleaning station locations and type will be identified prior to construction [Section 2.1 of Appendix C].	• Clubroot disease introduction and spread. Potato cyst nematode introduction and spread.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.11 Decreased soil productivity from soil diseases (*i.e.,* clubroot disease and potato cyst nematodes) (cont'd)	All	LSA	• If work is conducted in a high risk clubroot area/county and then equipment is mobilized to start work in a different area/county, a thorough cleaning will be performed prior to starting again on the new location [Section 2.1 of Appendix C]. • Rough cleaning using shovel and sweep cleaning to remove obvious clumps of soil is recommended between cultivated fields and quarter-sections (*e.g.,* at changes in land use and/or at road crossings) as a minimum measure in high risk locations such as Parkland County, Alberta to prevent movement of topsoil from one landowner to the next [Section 2.1 of Appendix C]. • The contractor will develop a documentation process to track compliance with the cleaning protocols in terms of what equipment/vehicles were cleaned, how and where [Section 2.1 of Appendix C]. • Refer to the Agricultural Management Plan for additional measures [Section 2.0 of Appendix C].	• Clubroot disease introduction and spread. Potato cyst nematode introduction and spread.
2. Soil Indicator – Soil Degradation				
2.1 Degradation of soil structure due to compaction and rutting	Edmonton to Hinton (Alberta) 26 soil units (see Soils Technical Report of Volume 5C) BC Pipeline Segments 36 soil units (see Soils Technical Report of Volume 5C)	Footprint	• Work during frozen soil conditions along the portions of the construction right-of-way where frozen soils are encountered during winter to ensure that there is sufficient frost or during periods of low soil moisture where frozen soil conditions are not encountered during winter (Lower Mainland Region of BC) to allow construction without causing excessive rutting or soil compaction [Section 8.3]. • Implement the Wet/Thawed Soils Contingency Plan (see Appendix B) during wet/thawed soil conditions in the event wet or thawed soils are encountered during construction [Section 8.2]. • Determine locations where subsoil compaction has occurred by comparing compaction levels on and off the construction right-of-way. Sites compared will be in close proximity and have similar drainage, soil moisture, aspect and land use, if feasible [Section 8.6]. • Rip compacted subsoils on the construction right-of-way adjacent to the ditchline and along shoo-flies with a multi-shank ripper or breaking disc to a depth of 30 cm or the depth of compaction, whichever is deeper. If soils are moist, postpone ripping of subsoils until soils dry to ensure that the soils fracture when ripped [Section 8.6]. • Employ a subsoiler plow (*e.g.,* Paratiller) along segments of the construction right-of-way adjacent to the ditchline where topsoil salvage did not occur and subsoil compaction is severe. Do not use a subsoiler plow on native grasslands [Section 8.6]. • Disc or chisel plow and harrow ripped subsoils to smooth the surface. Limit discing to that necessary to break up clods in order to prevent further compaction of the subsoils or to increase the potential for soil erosion by wind [Section 8.6]. • See additional measures to reduce compaction and rutting in Section 8.6 of the Pipeline EPP.	• Degradation of soil structure and impairment of rooting zone due to compaction and rutting.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.2 Loss of topsoil/root zone material through wind erosion	**Edmonton to Hinton (Alberta)** Carvel, Elk Point, gleyed Gabriel, Hoadley, Peace Hills, Primula, Rochester, peaty Rochester, shallow Rochester, Sundance, Winterburn **BC Pipeline Segments** 60 soil units (see Soils Technical Report of Volume 5C)	Footprint	<u>General</u> • Tackify or apply water/snow or pack the topsoil/root zone material windrow with a sheep foot packer or other approved equipment, if the assessment by the Inspector(s) indicates that soils are likely to be prone to erosion by wind (see Soil Erosion and Sediment Control Contingency Plan in Appendix B) [Section 8.2]. • Assess the wind erosion hazard, competency of the sod and potential for soil pulverization due to droughty soils. Implement measures applicable to droughty, wind erodible soils to reduce the impact of soil pulverization and wind erosion (see Soil/Sod Pulverization Contingency Plan in Appendix B) [Section 8.2]. • Apply water or approved tackifier to exposed soil piles if wind erosion occurs [Section 8.2]. • Monitor soils windrows during the growing season for wind and water erosion, and weed growth until the soils are replaced. Implement additional mitigation measures to control erosion (see Soil Erosion and Sediment Control Contingency Plan in Appendix B) and weed growth when warranted (see Weed and Vegetation Management Plan in Appendix C) [Section 8.2]. • Avoid removing excess small diameter slash in wooded areas with erodible soils [Section 8.6]. • Apply hydromulch/hydroseed at a rate recommended by the supplier on steep recontoured slopes and/or where soil wind erosion may be problematic (see Environmental Alignment Sheets) [Section 8.6]. • Seed disturbed erodible soils on non-cultivated land with a mixture of approved agronomic or native seed and cover crop seed such as fall rye if seeding in late summer or annual oats if seeding in the winter, spring or early summer [Section 8.6]. • See additional measures in the Soil Erosion and Sediment Control Contingency Plan and Soil/Sod Pulverization Contingency Plan in Appendix B of the Pipeline EPP. <u>Highly Erodible Soils</u> • Install erosion control blanket, coir/straw logs or rollback on exposed moderately to highly erodible soils where there is potential for water or wind erosion prior to re-establishment of vegetation (see Drawings [Rollback] and [Erosion Control – Rollback in Riparian Areas] and [Coir/Straw Log Installation] and [Erosion Control Matting/Blanket] provided in Appendix R) [Section 8.6]. • Conduct straw crimping on disturbed agricultural or native grassland soils where wind erosion may be problematic [Section 8.6]. See additional straw crimping measures in Section 8.6 of the Pipeline EPP. • Drill (during non-frozen soil conditions) or broadcast seed highly erodible cultivated lands with a cover crop of barley (var. Local Certified) or annual oats (var. Local Certified) at 45 kg/ha immediately following topsoil replacement [Section 8.6]. • Install temporary fences, if warranted, to restrict grazing and trampling of the seeded construction right-of-way until vegetation becomes established or less palatable [Section 8.6].	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.3 Loss of topsoil/root zone material through water erosion	All	Footprint	• Postpone root grubbing until immediately prior to grading along segments of the construction right-of-way where pre-clearing occurred and where there is a potential for soil erosion to occur, due to sloping terrain and erodible soils [Section 8.1]. See additional grubbing measures in Section 8.1 of the Pipeline EPP. • Leave breaks in the trench crown at obvious drainages and wherever seepage occurs to reduce or avoid interference with natural drainage. Leave breaks in the crown at frequent intervals where sidehill is encountered. Compact backfill where breaks have been left [Section 8.4]. • Install temporary sediment fences, where warranted, to control sedimentation prior to final clean-up and the establishment of permanent erosion and sediment control measures (see Drawing [Sediment Fence] provided in Appendix R) [Section 8.6.2]. • Implement the Soil Erosion and Sediment Control Contingency Plan [Section 8.0 of Appendix B]. • Replace grade material to a stable contour that will approximate the pre-construction contour, except where it is not practical or safe to do so. When replacing sidehill or other graded areas is not practical due to the risk of slope failure, the Lead Activity Inspector, the Lead Environmental Inspector, the Inspector(s), the Construction Manager and a Geotechnical Engineer will discuss to determine an appropriate grade [Section 8.4]. • Recontour the construction right-of-way, including the removal of temporary subsoil berms on agricultural land and re-establish the pre-construction grades and drainage channels if frozen soil conditions prevented completion of this task during backfilling [Section 8.6]. • Regrade areas with vehicle ruts, erosion gullies or where the trench has settled [Section 8.6]. • See additional measures to reduce water erosion at watercourses and wetlands in Sections 8.6 and 8.7 of the Pipeline EPP.	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.
2.4 Loss of topsoil/root zone material through surface water erosion on moderately steep slopes	Edmonton to Hinton (Alberta) Angus Ridge, Cooking Lake, Carvel, Hubalta, Modeste, Malmo, Primula, Winterburn BC Pipeline Segments 63 soil units (see Soils Technical Report of Volume 5C)	Footprint	• Install temporary berms on approach slopes to watercourses and erect sediment fence(s) near the base of approach slopes to watercourse(s) following grading (see Drawings [Cross Ditches and Diversion Berms] and [Sediment Fence] provided in Appendix R) where indicated on the Environmental Alignment Sheets. Inspect the temporary sediment control structures on a daily basis and repair, if warranted, before the end of each working day [Section 8.2]. • Install trench breakers (sack, foam or bentonite), where warranted, on moderate and steep slopes with high soil water erosion potential on non-agricultural lands to control subsurface flow (see Drawing [Trench Breakers/Ditch Plugs] provided in Appendix R) [Section 8.4]. • Install subdrains in association with trench breakers as directed by the Hydrogeological Resource Specialist where there is evidence of seepage or a flowing spring on a slope once the trench is excavated (see Drawing [Subdrains] provided in Appendix R) [Section 8.4]. • Install stub berms when directed by Trans Mountain, on sloping peatland terrain to prevent surface water flows along the trench line and erosion of trench backfill (see Drawing [Peatland Wetland – Stub Berms] provided in Appendix R) [Section 8.4].	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.4 Loss of topsoil/root zone material through surface water erosion on moderately steep slopes (cont'd)	Same as above	Footprint	• Install subsoil cross ditches and berms on steep and moderate slopes on tame pasture, and treed lands in order to prevent runoff along the construction right-of-way and subsequent erosion (see Drawing [Cross Ditches and Diversion Berms] provided in Appendix R) [Section 8.6]. • Recontour the construction right-of-way and stabilize approach slopes at watercourse crossings. Where reclamation of the pre-construction grade is not feasible due to risk of failure of fill on slopes or maintenance of an access trail, recontour to grades as directed by the Geotechnical Engineer [Section 8.6]. • Seed riparian areas with an approved annual or perennial grass cover crop or native grass mix as soon as feasible after construction. See additional measures outlined in the Reclamation Management Plan [see Appendix C]. • Install temporary erosion control measures such as temporary berms, sediment fences or cross ditches within 24 hours of backfilling banks and approach slopes of water crossings at any location where runoff from the construction right-of-way may flow into a watercourse. See additional measures outlined in the Reclamation Management Plan (see Appendix C) and aquatic resources (see Appendix J) [Section 8.6]. • Rollback slash and small diameter, salvageable timber on steep slopes and approach slopes to watercourses. Do not bury rollback when walking down with bulldozer. Leave gaps in rollback at all obvious wildlife trails [Section 8.6].	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.
2.5. Degradation of soil structure due to pulverization of soil and sod	All	Footprint	• Retain sod and the vegetation mat on all lands if a competent sod layer exists. In these areas, grade only where safety considerations dictate in order to reduce disturbance to sod and the vegetation mat. Grading of well-sodded lands will not be permitted on level terrain [Section 8.2]. • Assess the wind erosion hazard, competency of the sod and potential for soil pulverization due to droughty soils. Implement measures applicable to droughty, wind erodible soils to reduce the impact of soil pulverization and wind erosion (see Soil/Sod Pulverization Contingency Plan in Appendix B) [Section 8.2]. • Apply water or approved tackifier to disturbed areas if traffic and wind conditions result in pulverized soils and dust problems [Section 8.2]. • Cultivate or rip the full width of the construction right-of-way on cultivated fields and hay, tame pasture, bush or woodlands where poor sod development exists to a depth adequate to alleviate surface compaction and in a manner acceptable to the landowner. Do not cultivate into the subsoil [Section 8.6]. • Limit cultivation in areas of fine textured soils to prevent pulverization of the soil (see Soil/Sod Pulverization Contingency Plan in Appendix B) [Section 8.6]. • Disc and harrow only if the site is to be seeded immediately; otherwise, leave the ripped topsoil in a rough condition to reduce wind erosion potential [Section 8.6]. • Disc or rip disturbed soils on hay and tame pasture lands where the sod layer has been broken or where topsoils are compacted and reseeding is warranted [Section 8.6].	• Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.6. Erosion of soil as a result of release of hydrostatic test water on land	All	LSA	• Include resource-specific measures in water withdrawal plans (see Sections 7.0 and 8.0) to stabilize both the substrate of the water source and approaches to water sources to ensure that accelerated erosion will not occur during equipment installation, use or removal [Section 8.5]. • Monitor fill and discharge lines for leaks. Repair or control leaks to prevent erosion [Section 8.5]. • Collect pre-test pigging debris and water. Discharge the water at an acceptable location on-site in a manner that does not cause erosion or allow unfiltered or silted water to directly re-enter a waterbody/wetland/lake. Dispose of the remaining material with other construction waste, in accordance with appropriate federal and provincial guidelines [Section 8.5]. • Monitor discharge locations to ensure that no erosion, flooding or icing occurs. If conditions become saturated to the extent that adequate natural filtration is no longer occurring, suspend dewatering and move the discharge to another approved location (confirm that appropriate approvals and, if warranted, soil testing have been completed) or construct a holding pond for the water and release the water when natural filtration is feasible [Section 8.5].	• No residual effect identified.
2.7. Loss of topsoil/root zone material from disturbance (*e.g.,* maintenance dig activities) during operations	All	Footprint	• Implement the recommended soil handling procedures outlined in the Pipeline EPP to reduce the potential for soil degradation when maintenance activities involving soil disturbance are necessary during operations of the pipeline. • Monitor areas along the right-of-way that are disturbed during operations and maintenance activities. Implement remedial measures, where warranted.	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.
3. Soil Indicator – Bedrock and Stone Disposal				
3.1 Increased stoniness in surface horizons	Edmonton to Hinton (Alberta) stony Cooking Lake, shallow Rochester, shallow Rosevear BC Pipeline Segments bouldery Cheam 1, bouldery Kwikoit 1, bouldery Minnie, bouldery Roserim, bouldery Struthers 1, bouldery Stukemapten, Cheam 1, Harrison, Harrison 1, stony Glossey 1, stony Lucerne, stony Minnie, stony McQueen, stony Roserim, stony Timber, stony Woodley	Footprint	• Attempt to use conventional equipment to salvage topsoil/root zone material. Employ a backhoe if the conventional equipment is ineffective [Section 8.2]. • Surface stoniness on right-of-way will match that off right-of-way (stone size and density) on agricultural land and native grasslands. • Haul excavated trench spoil that is not suitable for use as backfill (*e.g.,* excess bedrock) and dispose of at locations approved by the Lead Environmental Inspector and the Inspector(s) [Section 8.3].	• Stone picking may result in disposal issues.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.2. Bedrock or large rocks within trench depth	Edmonton to Hinton (Alberta) shallow Bremay, shallow Dekalta, shallow Hubalta, Modeste BC Pipeline Segments bouldery Cheam 1, Modeste, shallow Bremay, shallow Dekalta, shallow Hubalta, shallow bouldery Stukemapten, shallow Allie, shallow bouldery Stukemapten, shallow Cheam, shallow Cheam 1, shallow Chasm, shallow Courtney, shallow Lucerne, shallow Minnie, shallow Roserim, shallow Snookwa, shallow Timber, shallow Tunkwa, shallow Tullee, shallow Tranquille, shallow Trapp Lake	LSA	• Rip bedrock in trench, if encountered and if feasible. Ripping is preferred over blasting [Section 8.3]. • Blast bedrock encountered within trench depth only if ripping or typical trenching methods are not feasible [Section 8.3]. See additional measures for blasting in Section 8.3 of the Pipeline EPP. • Haul excavated trench spoil that is not suitable for use as backfill (*e.g.,* excess bedrock) and dispose of at locations approved by the Lead Environmental Inspector and the Inspector(s) [Section 8.3]. • Ensure that bedrock excavated from the trench is not backfilled into the upper 50 cm of the trench if the potential exists for a reduction in agricultural capability. Dispose of excess bedrock at locations approved by the landowner/Crown land authority, where warranted, and the Lead Environmental Inspector and the Inspector(s). Known locations with shallow bedrock will be identified on the Environmental Alignment Sheets [Section 8.4]. See additional measures for bedrock in Section 8.4 of the Pipeline EPP.	• Removal of bedrock or large rocks from trench depth may result in disposal issues.
4. Soil Indicator – Soil Contamination				
4.1. Disturbance of previously contaminated soil	All	Footprint	• Avoid known areas of contaminated sediments. Implement the Contamination Discovery Contingency Plan (see Appendix B) in the event that contaminated sediments are discovered during construction. Adhere to applicable measures provided in the Waste Management Standard (see Appendix C) for handling of contaminated material [Section 7.0]. • Any sites contaminated by a spill will be assessed, remediation will be designed, and disposal sites will be identified in accordance with the *NEB Remediation Process Guide*. This document will be provided to the Construction Manager or designate, and the Lead Environmental Inspector(s) and Inspector(s) as part of the Environmental Education Program [Section 11.0 of Appendix B].	• No residual effect identified.
4.2 Contamination of soil as a result of release of hydrostatic test water on land	All	LSA	• Ensure that the appropriate testing and treatment measures are implemented in accordance with Sections 7(2) and 7(3) of the *BC Oil and Gas Waste Regulation* when dewatering in BC [Section 8.5]. • Ensure that the appropriate testing and treatment measures are implemented in accordance with provincial legislation, including Schedule 1, Requirements for Release to Land of the AESRD *Code of Practice for the Release of Hydrostatic Test Water from Hydrostatic Testing of Petroleum Liquid and Gas Pipelines* when dewatering in Alberta [Section 8.5]. • Conduct testing of the test water and soils at the discharge site, when required, and in accordance with applicable federal/provincial requirements [Section 8.5]. • Ensure that enough workers and equipment are available on-site to repair any rupture, leak or erosion problems that arise during testing [Section 8.5].	• No residual effect identified.

TABLE 7.2.2-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
4.2 Contamination of soil as a result of release of hydrostatic test water on land (cont'd)	All	LSA	• Dewater onto approved areas where water will be filtered through vegetation and soils before returning to a watercourse/wetland/lake. Provide scour protection (*e.g.,* use of rock aprons, plastic sheeting, plywood, straw bales) or an energy diffuser (*e.g.,* cone with baffles, frog's foot) at the discharge site as directed by Trans Mountain. The rate of discharge will be reduced if these measures are ineffective [Section 8.5]. • Dewater into a bar ditch, if feasible, or onto non-arable land. Do not dewater onto cultivated lands or directly back into a watercourse or watercourse/wetland/lake unless otherwise allowed by water discharge approvals and the Inspector(s) [Section 8.5]. • Collect samples of source water, hydrostatic test water and soil of the receiving environment and analyze according to the parameters listed in Water Withdrawal and Discharge Procedures Management Plan (see Appendix C) [Section 8.5].	• No residual effect identified.
4.3. Soil contamination due to spot spills during construction	All	Footprint	• Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are dumped on the ground or into watercourses/wetlands/lakes. In the event of a spill, implement the Spill Contingency Plan (see Appendix B) [Section 7.0]. • Place tarps or other impermeable material on the ground to catch drippings from coating application at weld joints and areas where repairs to the coating are made. Dispose of spilled coating at approved locations [Section 8.3]. • Isolate test pumps, generators and fuel storage tanks with an impermeable lined dike or depression to capture and retain any spills of fuels or lubricants [Section 8.5].	• No residual effect identified.

Notes: 1 LSA = Soil LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.2.2.5 Potential Residual Effects

The potential residual environmental effects on soil and soil productivity indicators associated with the construction and operations of the pipeline (Table 7.2.2-2) are:

- mixing of topsoil/root zone material and subsoil during topsoil/root zone material salvage, storage and replacement activities during both construction and maintenance activities including the effects associated with trench instability, shallow topsoil/root zone material depth and poor colour change;
- undesirable lower subsoils may be unexpectedly encountered and admixed with upper subsoil horizons;
- reduction in soil productivity on agricultural areas resulting from changes in evaporation and transpiration rates;
- excessive trench subsidence or a remnant crown;
- clubroot disease and potato cyst nematode introduction and spread;
- degradation of soil structure and impairment of rooting zone due to compaction and rutting;
- surface erosion of topsoil/root zone material can be expected until a vegetative cover is established;

- pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions; and
- stone picking and bedrock or large rock removal may result in disposal issues.

Some of the potential effects on soil and soil productivity associated with the construction and operations of the pipeline are predicted to be eliminated through the implementation of mitigation measures (Table 7.2.2-2). The potential effects determined not to have a residual effect are:

- decreased soil productivity from use of sand as bedding material;
- disturbance of previously contaminated soil;
- soil contamination due to spot spills during construction; and
- flooding, erosion or contamination of soil as a result of a release of hydrostatic test water.

7.2.2.6 Significance Evaluation of Potential Residual Effects

Where there are no standards, guidelines, objectives or other established and accepted ecological thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method is considered to be the appropriate method for determining the significance of the anticipated residual environmental effects. Consequently, a qualitative assessment of soil and soil productivity was determined to be the most appropriate method with the evaluation of significance of each of the potential residual effects relying on the professional judgment of the assessment team.

Table 7.2.2-3 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the proposed pipeline on soil and soil productivity. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.2-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON SOIL AND SOIL PRODUCTIVITY

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Soil Indicator – Soil Productivity

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Soil Indicator – Soil Productivity

The following provides the evaluation of significance of potential residual effects on the soil productivity indicator, including mixing of topsoil/root zone material and subsoil, mixing of undesirable lower subsoils with upper subsoil horizons, reduction in soil productivity due to changes in evaporation and transpiration, excessive trench subsidence or remnant crown, and clubroot disease/potato cyst nematode introduction and spread.

Topsoil/Root Zone Material and Subsoil Mixing

During the construction of the pipeline and, to a lesser extent, during maintenance activities, it is likely that a minor amount of topsoil/root zone material and subsoil mixing will occur along the proposed construction right-of-way. The impact balance of this residual effect is considered negative since admixing could decrease soil productivity. Participants of several of the community workshops (*e.g.,* Edmonton, Clearwater, Kamloops and Langley) noted the importance of proper management of topsoil, including handling and separation procedures, and emphasized that the rooting depth of soil is important for soil productivity on agricultural lands.

Since admixing can be alleviated over time through tilling, the addition of soil amendments (*e.g.,* green feed or manure), importation of topsoil or natural processes, the residual effect is reversible in the medium-term. Based on the results of a recent post-construction environmental monitoring program for a large pipeline project on agricultural lands, issues related to topsoil/subsoil mixing have been found to be resolved within 2 to 3 years (*i.e.*, in the medium-term) (TERA 2009a, 2011a, 2012a, 2013a). The results of the post-construction environmental monitoring program for the TMX Anchor Loop Project also demonstrated that topsoil/root zone material and subsoil mixing issues were resolved within 2 to 3 years in a forested setting (TERA 2009b, 2011b,c, 2013b). Similar mitigation measures are planned for the construction of the proposed pipeline.

Where topsoil/root zone material and subsoil admixing occurred along the TMX Anchor Loop Project route, results of the post-construction environmental monitoring reports indicated that admixing was minor/moderate and few locations required the addition of soil amendments to alleviate this effect (TERA 2009b, 2011b,c, 2013b). No areas with severe admixing were encountered during post-construction environmental monitoring for the TMX Anchor Loop Project (TERA 2009b, 2011b,c, 2013b). The results of another recent post-construction environmental monitoring program for a large pipeline project on agricultural lands also demonstrated that topsoil and subsoil mixing is generally minor in severity and is limited in extent (TERA 2009a, 2011a, 2012a, 2013a). Given the proven effectiveness of the mitigation measures to reduce admixing along the construction right-of-way, it is anticipated that the extent and severity of admixing will be minor. As a result, admixing is considered to be of low magnitude (Table 7.2.2-3, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – admixing is confined to the area of disturbance along the construction right-of-way.
- Duration: short-term – the events causing potential admixing are construction of the pipeline and maintenance-related activities, the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing potential admixing (*i.e.*, construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: medium-term – loss of soil productivity due to minor topsoil/root zone material and subsoil mixing is expected to be reversed within 10 years given the implementation of mitigation measures during construction and, if necessary, the application of soil amendments post-construction. The results of recent post-construction environmental monitoring programs in agricultural, forested and mountainous areas demonstrate that topsoil/root zone material mixing with subsoil is alleviated within a few years post-construction.
- Magnitude: low – given the implementation of industry-standard and provincial regulatory mitigation measures outlined in Table 7.2.2-2 and, if necessary, soil amendments applied post-construction. The results of recent post-construction environmental monitoring programs in agricultural, forested and mountainous areas demonstrate that topsoil/root zone material mixing with subsoil is generally minor in severity and limited in extent.
- Probability: high – admixing is a common residual effect of pipeline construction and may also occur during maintenance activities.
- Confidence: high – there is a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil productivity.

Undesirable Lower Subsoil/Upper Subsoil Mixing

Lower subsoils with a high gravel content may be unexpectedly encountered within a localized area during construction activities and admixed with upper subsoil horizons exhibiting less gravel content. The impact balance of this residual effect is considered negative since admixing could decrease soil productivity. The detailed soil survey (see Soils Technical Report of Volume 5C) and Environmental Alignment Sheets (Volume 6E) identify where the three-lift soil handling technique will be implemented (*i.e.*, Carvolth, Dixon, Fairfield 1, Hopedale, Struthers 2 overlying gravel and Sim soil series) to reduce the risk of mixing undesirable lower subsoils with upper subsoil, thereby maintaining the agricultural productivity of the soil. Three-lift soils handling was conducted on a recent large pipeline project on agricultural lands due to saline/sodic lower subsoils or lower subsoils with soil texture concerns (TERA 2009a). Based on the results of the Environmental As-built Report for that project, the three-lift soils handling technique was effective and localized issues related to poor crop growth due to problem lower subsoils (saline/sodic conditions or soil texture concerns) were resolved within 2 years post-construction (TERA 2009a, 2012a). Nevertheless, should some admixing of problem lower subsoils occur, the reversibility of mixing problem lower subsoils with upper subsoils could extend beyond 10 years. Similar mitigation measures as those outlined in Table 7.2.2-2 were effective in reducing the impairment of surface soils on past projects. Any admixing of undesirable lower subsoil with upper subsoil is expected to be limited in extent and, as a result, is considered to be of low magnitude (Table 7.2.2-3, point 1[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – admixing is confined to the area of disturbance along the construction right-of-way.

- Duration: short-term – the events causing potential admixing of problem subsoils are construction of the pipeline and maintenance-related activities, the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing potential admixing of problem lower subsoils with upper subsoils (*i.e.*, construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: medium to long-term – depending upon the amount of admixing and the textural composition of the subsoils.
- Magnitude: low – any admixing of undesirable lower subsoil with upper subsoil will be limited in extent and reduced by the industry-standard and provincial regulatory mitigation measures outlined in Table 7.2.2-2.
- Probability: high – the precision of soil mapping units to 250 m intervals on ALR lands (less dense on non-ALR lands) may result in short, localized segments of undesirable lower subsoils admixing with upper soil horizons.
- Confidence: high – a detailed soil survey along the pipeline corridor was conducted that identified areas of problem lower subsoils.

Evaporation and Transpiration

Loss of vegetation and soil disturbance will result in changes to evaporation and transpiration rates on agricultural areas following construction potentially reducing soil productivity. The potential effects on soil productivity will be reduced by scheduling construction activities in agricultural areas during late summer/fall in some areas when vegetation will be either desiccated or harvested and soil will likely be dry.

Segments of the construction right-of-way located on cultivated land will be returned to agricultural use following final clean-up. Following tilling and seeding activities, evaporation and transpiration rates on the construction right-of-way will not differ from off the construction right-of-way unless compaction or lower nutrient levels from admixing reduce vegetation yield. Mitigation measures outlined in Table 7.2.2-2 and the Pipeline EPP (Volume 6B) will reduce the potential for changes of soil structure and available environmental nutrients. Furthermore, any notable decrease in soil productivity will be identified during post-construction environmental monitoring and appropriate procedures will be implemented (*e.g.,* soil compaction alleviation, fertilization, landowner consultation).

The loss of vegetation on agricultural land will not result in any considerable alteration of wind patterns and resultant changes in evaporation rates of adjacent vegetation, nor are increased surface temperatures of bare soil resulting from losses in evaporative cooling expected to affect adjacent vegetation. In general, post-construction environmental monitoring reports for the TMX Anchor Loop Project and for a recent large pipeline project on agricultural lands demonstrate that soil productivity on right-of-way and off right-of-way are comparable with proper revegetation (TERA 2009a,b, 2011a,b,c, 2012a, 2013a,b). Locations along the construction right-of-way where seeding or natural revegetation have not been as successful will be recorded and appropriate measures will be implemented (*e.g.,* fencing to prevent grazing, reseeding, soil decompaction, fertilization).

Through appropriate scheduling and implementation of soil conservation and vegetation management measures in Table 7.2.2-2 and the Pipeline EPP (Volume 6B), the magnitude of changes in evaporation and transpiration resulting from pipeline construction is considered to be low. A reduction in soil productivity resulting from changes in evaporation and transpiration rates is considered reversible in the short to medium-term depending on land use, vegetation type and the success of soil handling and revegetation efforts (Table 7.2.2-3, point 1[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – reduction in soil productivity on agricultural areas resulting from changes in evaporation and transpiration rates are confined to the area of disturbance along the construction right-of-way.

- Duration: short-term – the events causing potential evaporation and transpiration rates are construction of the pipeline and maintenance-related activities, the latter of which are limited to any 1 year during the operations phase.

- Frequency: periodic – the events causing reduction in soil productivity on agricultural areas resulting from changes in evaporation and transpiration rates (*i.e.*, construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.

- Reversibility: short to medium-term – depending on vegetation type and success of soil handling and revegetation efforts, potential reduction in soil productivity resulting from changes in evaporation and transpiration rates may take up to or more than 1 year but less than 10 years to alleviate.

- Magnitude: low – given the implementation of industry-standard and provincial regulatory mitigation measures outlined in Table 7.2.2-2 and, if necessary, soil amendments applied post-construction. The results of recent post-construction environmental monitoring programs in agricultural, forested and mountainous areas demonstrate that changes in evaporation and transpiration rates are generally minor in severity and limited in extent.

- Probability: high – changes in evaporation and transpiration rates are common residual effects of pipeline construction and may also occur during maintenance activities.

- Confidence: moderate – there is a good understanding by the assessment team of cause-effect relationships between pipeline construction and changes in evaporation and transpiration rates from data outside of the Project area.

Trench Subsidence or Remnant Crown

Construction activities may result in localized areas of excessive trench subsidence and/or a remnant crown over the trench. The impact balance of this residual effect is considered negative since excessive trench subsidence or a remnant crown may reduce soil productivity through erosion and drainage issues. Trench subsidence and a remnant crown do not always occur during the year following construction and reclamation, and will be greatly influenced by the amount of precipitation. The reversibility of trench subsidence and/or a remnant crown is considered to be short to medium-term since remedial work associated with trench subsidence and/or a remnant crown typically occurs within a year of construction; however, localized trench subsidence may arise 2 to 3 years following construction (TERA 2009a,b, 2011a,b,c, 2012a, 2013a,b). Issues related to a remnant crown over the trench were not noted in the post-construction environmental monitoring reports for the TMX Anchor Loop Project or for a recent large pipeline project on agricultural lands (TERA 2009a,b, 2011a,b,c, 2012a, 2013a,b). With effective compaction of the backfilled trench and feathering out any remaining material over the trench, the magnitude of the effect of trench subsidence on soil and soil productivity is considered to be low (Table 7.2.2-3, point 1[d]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – trench subsidence or a remnant crown is confined to the trench line within the construction right-of-way.

- Duration: short-term – the event causing potential trench subsidence or a remnant crown is construction of the pipeline which is limited to the construction phase.

- Frequency: isolated – the event causing potential trench subsidence or a remnant crown (*i.e.*, construction activities) is confined to a specified phase of the assessment period.

- Reversibility: short to medium-term – remedial work associated with a remnant crown and trench subsidence typically is conducted within a year of construction, however, localized trench subsidence may also arise 2 to 3 years after construction.

- Magnitude: low – given the implementation of industry-standard and provincial regulatory mitigation measures outlined in Table 7.2.2-2 and, if necessary, soil amendments applied post-construction. The results of recent post-construction environmental monitoring programs in agricultural, forested and mountainous areas demonstrate that trench subsidence or a remnant crown is generally minor in severity and limited in extent.

- Probability: high – trench subsidence or a remnant crown is a common residual effect of pipeline construction.
- Confidence: high – there is a good understanding by the assessment team of cause-effect relationships between pipeline construction and trench subsidence/remnant crowns.

Clubroot Disease and Potato Cyst Nematode Introduction and Spread

Clubroot is a soil-borne disease that affects canola and other crops in the mustard family. It is considered a pest under the *Agricultural Pests Act* and was first detected in Alberta in a canola field near Edmonton in 2003. Clubroot disease is spread through resting spores in the soil which can survive for up to 20 years. Table C.1-1 in Appendix C of the Pipeline EPP (Volume 6B) summarizes known occurrences of clubroot in Alberta and BC. In Alberta, clubroot disease has been identified at 149 locations in Parkland County (Leskiw pers. comm.) and 3 locations in Yellowhead County (Pichette pers. comm.). In BC, clubroot disease has been found in cole crops in Fraser Valley (Joshi pers. comm.) and was noted as an issue in the Lower Mainland by participants of the Abbotsford ESA Workshop. Generally, the risk of clubroot disease is higher along the eastern portion of the proposed pipeline corridor (*i.e.*, Parkland County), where there are many confirmed cases of clubroot and lower western BC (*i.e.*, FVRD).

Potato cyst nematode is considered a pest under Alberta's *Agricultural Pests Act* and is regulated by the Canadian Food Inspection Agency (CFIA) under the *Plant Protection Act*. If potato cyst nematodes are confirmed at a given location, the CFIA may put the field under regulation. Potato cyst nematode regulated fields are monitored for access and equipment/vehicle sanitation. Furthermore, any equipment moving off a CFIA regulated field needs a CFIA Movement Certificate. Through landowner consultation, Trans Mountain has identified one cultivated field near Spruce Grove, Alberta that may be potentially contaminated with potato cyst nematode (Worobec pers. comm.).

Participants of the Abbotsford ESA Workshop expressed concern that a plan is needed for movement of personnel and equipment to ensure no cross-contamination of clubroot between fields. Mitigation measures outlined in Table 7.2.2-2 and the Pipeline EPP (Volume 6B) are consistent with recommended industry standard measures to reduce the introduction and spread of clubroot disease (Alberta Agriculture and Rural Development 2010, CAPP 2008) and potato cyst nematodes (CFIA 2012). The mitigation measures from Table 7.2.2-2 will be implemented during both construction and maintenance activities. Similar measures for clubroot were implemented for a large pipeline project on agricultural lands in Alberta, and post-construction environmental monitoring reports for that project indicate that no clubroot issues have been reported (TERA 2013b). This residual effect is reversible in the long-term and of high magnitude, however, progressive equipment cleaning measures to be implemented during construction of the Project ensure that the potential effect is unlikely to occur (Table 7.2.2-3, point 1[e]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Soil LSA – clubroot disease and potato cyst nematodes could spread beyond the construction right-of-way.
- Duration: short-term – the events causing potential soil disease introduction and spread (construction of the pipeline and maintenance activities) occur during the construction phase or are completed within any 1 year during the operations phase.
- Frequency: accidental – introduction or spread of clubroot disease/potato cyst nematodes is rare when the mitigation measures in Table 7.2.2-2 are implemented.
- Reversibility: long-term – once introduced or spread, the effects of clubroot disease/potato cyst nematodes may take longer than 10 years to be reversed.
- Magnitude: high – the residual effect of introduction or spread of clubroot disease/potato cyst nematodes is considered to be beyond environmental standards.

- Probability: low – all required mitigation measures will be implemented during construction to prevent the introduction and spread of clubroot disease and potato cyst nematodes.
- Confidence: moderate – there is a good understanding by the assessment team of cause-effect relationships between pipeline construction and potential soil disease introduction and spread.

Combined Effects on Soil Productivity

The following assesses the combined effects on the soil productivity indicator that could potentially occur. Only those residual effects that are likely to occur have been considered in the overall effects on the soil productivity indicator. The potential exists for the following potential residual effects to occur and contribute to overall effects on the soil productivity indicator:

- mixing of topsoil/root zone material and subsoil;
- undesirable lower subsoils may be unexpectedly encountered and admixed with upper subsoils;
- reduction in soil productivity on agricultural areas from changes in evaporation and transpiration rates; and
- excessive trench subsidence or a remnant crown.

The combined effects on the soil productivity indicator of these potential residual effects would be not significant due to the overall low magnitude of the potential effects which is based in part on the limited areal extent where the effects would occur (*i.e.*, localized areas on the Footprint) (Table 7.2.2-3, point 1[f]). In addition, effects on soil will be monitored as part of the post-construction environmental monitoring program (Volume 6A). A summary of the rationale for all of the significance criteria on the combined effects on the soil productivity indicator is provided below.

- Spatial Boundary: Footprint – combined effects on the soil productivity indicator are confined to the area of disturbance along the construction right-of-way.
- Duration: short-term – the events causing combined effects on the soil productivity indicator are construction of the pipeline, and maintenance-related activities which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing combined effects on the soil productivity indicator (*i.e.*, construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short to long-term – combined effects on the soil productivity indicator are anticipated to take less than 10 years to reverse but could take more than 10 years to reverse where there is admixing of undesirable lower subsoils with upper subsoils.
- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the combined effects on soil productivity.
- Probability: high – the individual effects on the soil productivity indicator are likely to occur in combination.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil productivity.

Soil Indicator – Soil Degradation

The following provides the evaluation of significance of potential residual effects on the soil degradation indicator, including degradation of soil structure from compaction and rutting, surface erosion and soil/sod pulverization.

Degradation of Soil Structure from Compaction and Rutting

Soil compaction, as a result of construction activities, can result in the reduction of soil pore space and an increase of soil bulk density or mass. Plant roots have greater difficulty penetrating compacted soil which can reduce the productivity of plant communities. Rutting can occur by vehicle traffic during wet conditions. The impact balance of this residual effect is considered negative since compaction and rutting could decrease the structure of the soil and, therefore, reduce soil productivity. Based on the results of a recent post-construction environmental monitoring program for a large pipeline project on agricultural lands, issues related to compaction and rutting have been found to be resolved within 1 to 2 years (*i.e.*, in the short to medium-term) (TERA 2009a, 2011a, 2012a, 2013a). The results of the post-construction environmental monitoring program for the TMX Anchor Loop Project also demonstrated that rutting issues were typically resolved within 2 years in a forested setting (TERA 2009b, 2011b,c, 2013b). Similar mitigation measures are planned for the construction of the proposed pipeline.

Given the proven effectiveness of the mitigation measures to reduce admixing along the construction right-of-way, it is anticipated that the extent and severity of compaction and rutting will be minor. As a result, this residual effect is considered to be of low magnitude (Table 7.2.2-2, point 2[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – degradation of soil structure from compaction and rutting is confined to the area of disturbance along the construction right-of-way.
- Duration: short-term – the events causing potential degradation of soil structure from compaction and rutting are construction of the pipeline and maintenance-related activities, the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing potential degradation of soil structure from compaction and rutting (*i.e.*, construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short to medium-term – degradation of soil structure from compaction and rutting is expected to be reversed within a few years given the implementation of mitigation measures during construction and, if necessary, the application of soil amendments post-construction.
- Magnitude: low – given the implementation of industry-standard and provincial regulatory mitigation measures outlined in Table 7.2.2-2 and, if necessary, soil amendments applied post-construction.
- Probability: high – degradation of soil structure from compaction and rutting is a common residual effect of pipeline construction and may also occur during maintenance activities.
- Confidence: high – there is a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil degradation.

Surface Erosion of Topsoil/Root Zone Material

Construction and maintenance activities which disturb the soil will likely result in some surface erosion of topsoil/root zone material until a stable vegetative cover can be established, particularly on slopes which are more susceptible to water erosion. The impact balance of this residual effect is considered negative since erosion could decrease soil productivity. Soil erosion was noted as a concern by stakeholders, including participants of the Wabamun, Hinton, Valemount and Kamloops Community Workshops. It is expected that a vegetative cover can be established on non-cultivated disturbed slopes within a year with the seeding of a rapidly establishing cover crop in addition to the appropriate seed mix for the location. Based on the results of post-construction monitoring programs for pipeline projects in agricultural and forested settings, issues related to erosion can generally be resolved within 2 to 3 years following final clean-up (TERA 2009a,b, 2011a,b,c, 2012a, 2013a,b). Similar measures are planned for the construction of the proposed pipeline. Consequently, minor surface erosion of topsoil/root zone material is considered to be reversible in the medium-term.

A participant of the Hinton Community Workshop noted that eolian soils are present under the vegetation mat in the Hinton area and may be difficult to reclaim. Eolian and sandy textured soils were also noted as an erosion concern along the TMX Anchor Loop Project pipeline route. However, results of the post-construction environmental monitoring program for this project did not reveal any extraordinary issues related to wind erodible soils and, as stated above, issues related to erosion were generally resolved within 2 to 3 years following final clean-up (TERA 2009b, 2011b,c, 2013b). The erosion control measures outlined in Table 7.2.2-2 to address soil erosion are the industry-accepted standards and, consequently, are expected to reduce loss of surface soils resulting from erosion to minor levels. Given the proven effectiveness of the mitigation measures to reduce erosion outlined in Table 7.2.2-2, this residual effect is considered to be of low magnitude (Table 7.2.2-3, point 2[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – surface erosion is confined to the area of disturbance along the construction right-of-way.
- Duration: short-term – the events causing surface erosion are construction of the pipeline and maintenance-related activities, the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing surface erosion (*i.e.*, construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: medium-term – surface erosion is generally expected to be reversed within 2 to 3 years given the implementation of mitigation measures during construction and, if necessary, the application of soil amendments post-construction.
- Magnitude: low – given the implementation of industry-standard and provincial regulatory mitigation measures outlined in Table 7.2.2-2 and, if necessary, soil amendments applied post-construction.
- Probability: high – surface erosion is a common residual effect of pipeline construction which can be addressed during post-construction environmental monitoring and may also occur during maintenance activities.
- Confidence: high – there is a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil degradation.

Degradation of Soil Structure from Pulverization

Construction activities during dry conditions may result in pulverization of soil and sod along the proposed pipeline corridor. The impact balance of this residual effect is negative since pulverization of soil and sod could lead to increased fugitive dust and loss of soil structure. Given the mitigation measures in Table 7.2.2-2 to reduce soil/sod pulverization, including the Soil/Sod Pulverization Contingency Plan, degradation of soil structure from pulverization is considered to be reversible in the short to medium-term (Table 7.2.2-3, point 2[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – degradation of soil structure from pulverization is confined to the area of disturbance along the construction right-of-way.
- Duration: short-term – the event causing degradation of soil structure from pulverization is construction of the pipeline.
- Frequency: isolated – the event causing degradation of soil structure from pulverization (*i.e.*, construction of the pipeline) is confined to a specified phase of the assessment period.
- Reversibility: short to medium-term – effects related to dust are reversible in less than 1 year (short-term); while the effects related to loss of soil structure is expected to take more than 1 year but less than 10 years to reverse the effect (medium-term).
- Magnitude: low – given the implementation of mitigation measures outlined in Table 7.2.2-2 and, if necessary, soil amendments applied post-construction.

- Probability: low to high – degradation of soil structure from pulverization is a common residual effect of pipeline construction but only in dry conditions so the likelihood varies by location along the construction right-of-way and weather conditions.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on Soil Degradation

The following assesses the residual effects that could potentially contribute to overall effects on the soil degradation indicator. Only those residual effects that are likely to occur have been considered in combination, including:

- degradation of soil structure and impairment of rooting zone due to compaction and rutting;
- surface erosion of topsoil/root zone material can be expected until a vegetative cover is established; and
- pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.

The combined effects on the soil degradation indicator of these potential residual effects would be not significant due to the overall low magnitude of the potential effects which is based in part on the limited areal extent where the effects would occur (*i.e.*, localized areas on the Footprint) (Table 7.2.2-3, point 2[d]). In addition, effects on soil will be monitored as part of the post-construction environmental monitoring program (Volume 6A). A summary of the rationale for all of the significance criteria of combined effects on the soil degradation indicator is provided below.

- Spatial Boundary: Footprint – combined effects on the soil degradation indicator are confined to the area of disturbance along the construction right-of-way.
- Duration: short-term – the events causing combined effects on the soil degradation indicator are construction of the pipeline and maintenance-related activities, the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing combined effects on the soil degradation indicator (*i.e.*, construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short to medium-term – combined effects on the soil degradation indicator are expected to be reversed within 1 year, or in more than 1 year but less than 10 years given the implementation of mitigation measures during construction and, if necessary, the application of soil amendments post-construction.
- Magnitude: low – combined effects on the soil degradation indicator are anticipated to be reduced through the implementation of industry standard and provincial regulatory mitigation measures and, if necessary, soil amendments applied post-construction.
- Probability: high – the individual effects on the soil productivity indicator are likely to occur in combination.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil degradation.

Soil Indicator – Bedrock and Stone Disposal

The following provides the evaluation of significance of potential residual effects on the bedrock and stone disposal indicator.

Disposal Issues Resulting from Stone Picking and Removal of Bedrock from the Trench

Stones picked from the top of the backfilled subsoil and from the topsoil/root zone material as well as bedrock or large rock removed from the trench by ripping or blasting may result in disposal issues depending on the volume accumulated. Stones/large rocks may be disposed of off right-of-way, including areas within the Soil LSA, depending on landowner or Crown land authority preferences. Spoil removal in urban areas was also mentioned by a participant at the Surrey ESA Workshop. Similar to disposal of stones/large rocks, excess spoil in urban areas may also need to be disposed of off right-of-way and hauled away to an approved location.

Stone picking was conducted during clean-up activities for a large pipeline project on agricultural lands in 2009 (TERA 2009c). Following the 2011 post-construction environmental monitoring program for the pipeline, all sites previously identified as requiring additional stone picking were resolved (TERA 2012a). Although there is potential to encounter bedrock within trench depth along the proposed pipeline corridor, these areas are very minor in extent and conventional trenching methods are anticipated to be successful for most locations. However, localized blasting is anticipated along the Edmonton to Hinton, Hargreaves to Darfield, Black Pines to Hope and Hope to Burnaby segments. The impact balance of this effect is considered to be negative since excess stones can impact the management of soils on agricultural lands. The magnitude of this residual effect is considered to be low (Table 7.2.2-3, point 3[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Soil LSA – excess stones or bedrock originating from disturbed portions of the construction right-of-way (*i.e.,* Footprint), may result in disposal off right-of-way, including areas within the Soil LSA, depending on landowner or government land authority preferences.
- Duration: short-term – the event causing disposal issues resulting from stone picking and removal of bedrock from the trench is construction of the pipeline.
- Frequency: isolated – the event causing disposal issues resulting from stone picking and removal of bedrock from the trench (*i.e.*, construction activities) is confined to a specified phase of the assessment period.
- Reversibility: short to medium-term – excess bedrock is typically disposed of within a year of construction while excess stones at the surface can occur beyond the first year of post-construction but are typically resolved within 1 to 2 years.
- Magnitude: low – given the implementation of mitigation measures outlined in Table 7.2.2-2 and through post-construction environmental monitoring which will address any issues of surface stoniness after construction.
- Probability: high – based on similar projects, disposal issues resulting from stone picking and removal of bedrock from the trench are a common residual effect of pipeline construction.
- Confidence: high – there is a good understanding by the assessment team of cause-effect relationships between pipeline construction and bedrock and stone disposal.

Soil Indicator – Soil Contamination

No residual effects of the construction and operations of the proposed pipeline were identified for the soil contamination indicator (Table 7.2.2-3). Consequently, no further assessment is warranted.

7.2.2.7 Summary

As identified in Table 7.2.2-3, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on soil and soil productivity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline construction and operations on soil and soil productivity will be not significant.

7.2.3 Water Quality and Quantity

This subsection describes the potential Project effects on surface water quality and quantity and groundwater quality. The Fisheries (Alberta) Technical Report and Fisheries (British Columbia) Technical Report of Volume 5C provide further information pertaining surface water quality and quantity along the proposed pipeline corridor, while the Groundwater Technical Report of Volume 5C provides further information pertaining to existing groundwater conditions along the proposed pipeline corridor.

7.2.3.1 Assessment Indicators and Measurement Endpoints

Assessment indicators identified for the water quality and quantity element are: surface water quality; surface water quantity; groundwater quality; and groundwater quantity. Assessment indicators and measurement endpoints for water quality and quantity are listed in Table 7.2.3-1. Surface water quality and quantity indicator selection considered: filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues, such as the TMX Anchor Loop Project; feedback from Aboriginal communities, regulatory authorities, stakeholders; available research literature; feedback from participants in ESA Workshops; public issues raised through the media; and the professional judgment of the assessment team. A list of the proposed surface water quality and quantity indicators was discussed during the ESA Workshops. Participants in the Edmonton, Kamloops and Surrey ESA Workshops questioned how surface water quality would be adequately assessed, and suggested that existing benthic invertebrate and sediment conditions be used as a water quality indicator. A response to these stakeholder recommendations is provided in Section 7.2.3.4. Otherwise, there was general consensus among workshop participants that the proposed surface water indicators were appropriate for evaluating Project effects on surface water quality and quantity.

The selection of indicators for groundwater quality and quantity was based on the NEB *Filing Manual* requirements, experience gained during previous projects with similar conditions/potential issues, feedback from stakeholders, available research literature including various maps, drilling records, water wells, groundwater information, field inspection and the professional judgment of the assessment team. The proposed groundwater quality and quantity indicators were discussed during the Edmonton, Kamloops and Surrey ESA Workshops. The workshop participants generally agreed that the proposed groundwater indicators were appropriate for evaluating the effects of the Project on groundwater quality and quantity. Upon consideration by the assessment team, contaminated groundwater migration was considered to be already covered by the other indicators. Input was also sought from Environment Canada, AESRD, BC MOE and BC MFLNRO and these agencies were in agreement that the proposed groundwater indicators were appropriate and suggested no additional indicators for consideration.

Qualitative measurement endpoints are applied to assess potential Project effects on water quality and quantity indicators (Table 7.2.3-1).

TABLE 7.2.3-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR WATER QUALITY AND QUANTITY

Water Quality and Quantity Indicators	Measurement Endpoints	Rationale for Indicator Selection
Surface water quality	• Areas with high water table susceptible to trench instability • Suspended sediment in water column • Approach slopes susceptible to erosion • Drilling mud release • Hydrostatic test water withdrawal and release locations • Surface water contamination	The selection of indicators and measurement endpoints considered NEB *Filing Manual* requirements for the water quality and quantity element under Table A-2 and addressed concerns raised through Aboriginal engagement and stakeholder consultation.
Surface water quantity	• Surface drainage patterns • Disruption of streamflow • Hydrostatic test water withdrawal and release locations	

TABLE 7.2.3-1 Cont'd

Water Quality and Quantity Indicators	Measurement Endpoints	Rationale for Indicator Selection
Groundwater quality	• Shallow groundwater with potential existing contamination • Areas susceptible to drilling mud release during HDD construction • Areas in the aquifer susceptible to sedimentation • Areas of shallow groundwater susceptible to blasting effects • Areas with potential artesian conditions • Aquifers or wells vulnerable to possible future contamination from an accident or malfunction	The selection of indicators and measurement endpoints considered the NEB *Filing Manual* requirements for the water quality and quantity element under Table A-2 and addressed concerns raised by participants of the ESA Workshops and was informed by regulatory authorities (*i.e.,* Environment Canada, AESRD, BC MOE and BC MFLNRO). Groundwater will not be used for hydrostatic testing, therefore, groundwater withdrawal or discharge for this purpose has not been considered. Groundwater use requirements at Trans Mountain facilities will not increase with the proposed expansion activities.
Groundwater quantity	• Areas susceptible to changes in groundwater flow patterns • Areas where dewatering may be required during pipeline construction activities • Areas with potential artesian conditions • Areas shallow groundwater susceptible to blasting effects	

7.2.3.2 Spatial Boundaries

The following spatial boundaries are used in the water quality and quantity effects assessment:

- a Footprint Study Area (as defined in Section 7.1.3);
- a Water Quality and Quantity LSA; and
- an Aquatics RSA.

The Water Quality and Quantity LSA reflects the area where Project construction and operations activities would most likely affect water quality and quantity. The direct disturbance ZOI is defined as the area extending 100 m upstream of the centre of the proposed pipeline corridor to a minimum of 300 m downstream of the centre of the proposed pipeline corridor. For groundwater, the area within 300 m of the proposed pipeline corridor, facility or HDD entrance in potentially vulnerable aquifer areas in hydraulic connection with the Footprint constituted the Water Quality and Quantity LSA. The downstream Water Quality and Quantity LSA boundary of each watercourse crossed by the proposed pipeline corridor was determined by the ZOI, the reach where 90% of the sediment load caused by construction activities is expected to fall out of suspension (Government of Alberta 2013b,c). The ZOI was determined in the field based on the professional experience and judgment of the Qualified Aquatic Environmental Specialist (QAES) in Alberta or the Qualified Environmental Professional (QEP) in BC who considered relevant site-specific factors (*e.g.,* stream gradient, channel width, channel depth, substrate composition, channel morphology, flow velocity and discharge and instream cover). Due to variable drainage patterns along the proposed pipeline corridor, it is not feasible to accurately map the Water Quality and Quantity LSA using the above-mentioned definition. Consequently, for illustrative purposes, Figures 7.2.7-1 and 7.2.7-2 of Section 7.2.7 provide examples of the Water Quality and Quantity LSA at watercourses of varying size. The Water Quality and Quantity LSA boundaries for each watercourse can be found in the Summary Crossing Table (Appendix A of the Fisheries [Alberta] Technical Report and the Fisheries [British Columbia] Technical Report of Volume 5C).

The Aquatics RSA includes all watersheds affected by the Project (as defined in Section 5.7 of the Fisheries [Alberta] Technical Report and the Fisheries [British Columbia] Technical Report of Volume 5C). These watersheds include the area where the direct and indirect influence of other land uses and activities could overlap with proposed Project-specific effects and cause cumulative effects on the water quality and quantity indicators for surface water. The Aquatics RSA does not apply to groundwater indicators since potential effects on groundwater quality and quantity are not anticipated beyond the Water Quality and Quantity LSA. The Aquatics RSA is shown on Figures 5.3-1 and 5.3-2.

The Water Quality and Quantity LSA and Aquatics RSA were discussed during the ESA Workshops and with Environment Canada, AESRD, BC MOE and BC MFLNRO (Section 3.0). There was general agreement that the spatial boundaries for water quality and quantity were appropriate and no alternative boundaries were suggested for consideration by the assessment team.

7.2.3.3 Water Quality and Quantity Context

The proposed pipeline corridor lies within four drainage basins, including the North Saskatchewan and Athabasca river basins in Alberta and the Fraser and Columbia river basins in BC. Twenty-one Project watersheds are crossed by the proposed pipeline corridor as described in Section 5.7 of the Fisheries (Alberta) and Fisheries (British Columbia) Technical Reports of Volume 5C and as shown on Figures 5.3-1.

Potential watercourses along the proposed pipeline corridor were originally identified during helicopter overflights and from desktop analysis. The 2012 and 2013 fisheries field program investigated 928 potential watercourses crossed by the proposed pipeline corridor (including 10 watercourses that were assessed based on historical information). Ongoing fisheries field studies are discussed in Section 9.0. It was determined that 88 defined watercourses are crossed by the proposed pipeline corridor in Alberta and 386 in BC. Named rivers crossed by the proposed pipeline corridor in Alberta include the North Saskatchewan, Pembina and McLeod rivers. The proposed pipeline corridor crosses 14 named rivers in BC, including the Fraser, North Thompson, Thompson, Coldwater and Coquihalla rivers.

A variety of surficial deposits and bedrock formations occur along the proposed pipeline corridor. Through most of Alberta, south of Kamloops and through the Burnaby area, fine-grained clay till deposits are predominant. However, where the proposed pipeline corridor either parallels in close proximity or crosses a large watercourse, fluvial or glaciofluvial deposits are more common (*e.g.,* Chilliwack area). Coarser grained surficial materials such as sand and gravel, components of fluvial and glaciofluvial deposits, are generally more permeable, facilitating groundwater flow and potential contaminant transport.

Section 5.3 and the Groundwater Technical Report of Volume 5C provide additional setting information related to water quality and quantity along the proposed pipeline corridor.

7.2.3.4 Potential Effects and Mitigation Measures

<u>Effects Considerations</u>

In a letter to Trans Mountain dated June 19, 2012, Enoch Cree Nation expressed concern over potential effects to water quality from herbicide use during post-construction weed management activities. Measures provided in the Weed and Vegetation Management Plan of the Pipeline EPP (Volume 6B), such as prohibiting the use of herbicides within 30 m of a watercourse or waterbody, will be implemented to avoid any potential effects to water quality and, therefore, this potential effect was not carried through the assessment.

A participant at the Wabamun Community Workshop noted that soils in the Wabamun Lake area have a high phosphorous content which, if exposed as a result of pipeline construction, could affect water quality of Wabamun Lake. Standard sediment erosion control measures provided in the Pipeline EPP (Volume 6B) will be implemented to reduce or limit the extent of site runoff. Consequently, given that the proposed pipeline corridor is located approximately 350 m north of the lake at its nearest point (RK 113), any runoff of phosphorus-laden sediment is not expected to reach Wabamun Lake and, therefore, this potential effect was not carried through the assessment.

Naturally occurring deposits of asbestos are known to occur within the Sumas River and Sumas Lake Canal, which is crossed by the proposed pipeline corridor at RK 1114.6 and RK 1110.7, respectively. In order to negate any potential effects to water quality as a result of sediment disturbance, these watercourses will be crossed using a trenchless method and, therefore, this potential effect was not carried through the assessment.

As previously mentioned, participants at the ESA Workshops suggested sediment sampling and benthic invertebrate studies as measurement endpoints for the surface water quality indicator. For reasons provided in the following subheadings, conventional pipeline assessment and monitoring methods will be implemented for the Project that do not include sediment sampling and benthic invertebrate studies.

Sediment and Water Quality Testing

Through water quality monitoring over the years (*e.g.,* TERA 2009a), there is good confidence in concluding that effects of pipeline associated watercourse crossings are limited to increased sediment input and deposition, and this influences the type of data collection and monitoring program design. Due to the inherent variability in water quality, baseline water quality data for parameters such as heavy metals, nutrient loads and bacteria, and sediment quality, are no longer routinely collected since the construction and operations of the pipeline itself will not involve any additional contribution of effluents and chemicals that would increase current contaminant levels. Emphasis is now placed on monitoring water quality during construction and post-construction. In addition to previous experience and results of peer-reviewed research on the effects of pipeline crossings and increased sedimentation, potential effects on surface water quality were identified based on regulatory guidance materials including the Pipeline Associated Watercourse Crossings: 3rd Addition (CAPP *et al.* 2005), Standards and Best Practices for Instream Works (BC Ministry of Water, Land and Air Protection [MWLAP] 2004a) and Guide to the Code of Practice for Watercourse Crossings (Government of Alberta 2013b).

Watercourses along the proposed pipeline corridor were examined to document site-specific features. Field data consisting of both qualitative observations (*e.g.,* habitat quality, turbidity, bed and bank characteristics, riparian health) and quantitative data collection (*e.g.,* pH, dissolved oxygen, conductivity, temperature, fish sampling) to identify existing water quality conditions and the likely ZOI for sediment effects. Available water quality information was also obtained from provincial and federal water quality monitoring programs (Section 5.3).

Sediment testing is only considered necessary for pipeline crossings where existing contaminants (from historic contamination) bound within the streambed sediments have the potential to become entrained in the water column as a result of instream construction activities. Otherwise, potential effects resulting from re-suspension of uncontaminated materials are not unlike those resulting from seasonal fluctuations in turbidity and total suspended solids (TSS) from natural processes. If contamination was suspected at any watercourse, sediment samples would be collected to determine potential effects. For example, sediment quality was sampled at the Westridge Marine Terminal in Burrard Inlet for this reason (refer to Section 7.6.7). In the event areas of contaminated sediments are encountered during construction, the Contaminated Sites Discovery Contingency Plan in Appendix B of the Pipeline EPP (Volume 6B) will be implemented and procedures outlined in the *NEB Remediation Process Guide* (NEB 2011) will be followed.

Site-specific sediment and/or water quality testing may, however, be warranted for several other Project activities, including:

- hydrostatic test water discharge areas, which are considered as measurement endpoints of the water quality indicator (Table 7.2.3-1);
- contamination resulting from large spills, which are considered in Volume 7;
- potential acid rock drainage near waterbodies (Section 7.2.1);
- stormwater discharge locations at pump stations (Section 7.4.3) and terminals (Section 7.5.3); and
- waste water discharge locations from work camps (Section 7.3.3).

Benthic Invertebrates

Pollution in sediments influences the development of benthic invertebrates, the base of the food chain, and can lead to modification of the whole ecological structure (Beasley and Kneale 2002). Benthic invertebrates are a useful indicator of water quality for effluent discharge, but may not be the most practical indicator to use for short-term disturbances such as those from pipeline watercourse crossings. However, that does not suggest potential effects to benthic invertebrates from increased suspended solids at pipeline watercourse crossings should be overlooked. Benthic invertebrates are an important food source for many aquatic organisms, including fish and, consequently, are considered under the fish and fish habitat element (Section 7.2.7).

Newcombe's work on sediment dose-response relationships (Newcombe 1994) identified that impacts to benthic invertebrates are directly related to concentration and duration of TSS in a watercourse. Previous studies on pipeline watercourse crossings (*e.g.,* Reid and Anderson 1999, Reid *et al.* 2002a, Tsui and McCart 1981, Wood and Armitage 1997, Young and Mackie 1991) showed that benthic invertebrate populations are normally able to withstand short-term increases in suspended sediment and recover quickly following open cut (trenched) crossings. Consequently, in recent years, the focus has shifted from pre-disturbance testing and monitoring to sediment and habitat monitoring during and following instream construction activities.

In accordance with CCME guidelines for particulate matter, pipeline crossings are monitored during construction to ensure sediment concentrations do not exceed 25 mg/L from background levels in a 24 hour period and turbidity does not exceed 8 NTU from background levels in a 24 hour period in accordance with CCME guidelines for total particulate matter (CCME 2002). With this standard industry guidance, effects from instream pipeline crossings on benthic invertebrates are expected to be within an acceptable range. Consequently, benthic invertebrates as a measure of surface water quality were not carried through the assessment.

Identified Potential Effects

Potential effects of pipeline construction and operations on water quality and quantity indicators are listed in Table 7.2.3-2. These interactions are based on results of the literature review, desktop analysis, field work, TEK, engagement with Aboriginal communities landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

Issues and concerns related to surface water quality and quantity identified by participating Aboriginal communities through the biophysical field studies for the Project are described in the Fisheries (Alberta) and Fisheries (British Columbia) Technical Reports of Volume 5C. A comprehensive review of the issues raised by participating Aboriginal communities was conducted with each community during the field surveys and during follow-up results review meetings (see the Fisheries [Alberta] Technical Report and the Fisheries [British Columbia] Technical Report of Volume 5C).

Standard pipeline construction activities are designed to avoid diversion and/or unnatural retention of water along the construction right-of-way by following recommendations from various industry and provincial guidelines (AENV 1988, 1994a; BC OGC 2013; CAPP 1999; CAPP *et al*. 2005). In addition, applicable measures from several industry and provincial and federal regulatory guidelines have been incorporated into Table 7.2.3-2 to reduce the potential effects of pipeline construction and operations on water quality and quantity including Alberta Energy Regulator (AER) (2001), AEP (1999), BC MWLAP (2004a), Canadian Pipeline Environment Committee (2009), CAPP (1996, 2004), DFO (1995, 1999, 2007a,b) and Government of Alberta (2001, 2013a,b,c), as well as groundwater legislation under the *Oil and Gas Activities Act* (*Environmental Protection and Management Regulation*) and the *BC Environmental Assessment Act.*

In Table 7.2.3-2, RK values in the Pipeline Segments column refer to locations where potential effects may be encountered and are shown on the Environmental Alignment Sheets (Volume 6E).

TABLE 7.2.3-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON WATER QUALITY AND QUANTITY

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Water Quality and Quantity Indicator – Surface Water Quality				
1.1 Instability of trench at locations with high water table	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	LSA	• Dewater the trench, if warranted, when laying pipe in areas with high water tables. Place pumps on polyethylene sheeting above the ordinary high water mark of the watercourse. Pump water onto stable and well vegetated areas, tarpaulins or sheeting at least 50 m from the nearest waterbody in a manner that does not cause erosion or any unfiltered or silted water to re-enter a watercourse [Section 8.3]. See additional dewatering measures in Section 8.3 of the Pipeline EPP. • Monitor the water discharge site to ensure that erosion, saturation of the discharge site, flooding, icing or flow off of the property does not occur. Suspend dewatering and either apply erosion control measures, reduce the flow or move the discharge site if it appears that the above effects could occur [Section 8.3]. • See recommended mitigation measures outlined in Table 7.2.8-2 Wetland Loss or Alteration.	• No residual effect identified.
1.2 Suspended sediment concentrations in the water column during instream activities	All	LSA	Pipeline Crossings • Appropriate watercourse crossing methods have been selected in consideration of the size, environmental sensitivities of the watercourses and period of construction (Appendix A of the Fisheries [Alberta] and Fisheries [British Columbia] Technical Reports of Volume 5C). • Install the pipeline at each watercourse using the technique as identified in environmental resource-specific mitigation table for aquatic resources in Appendix I of the Pipeline EPP and as shown on the Environmental Alignment Sheets (Volume 6E). Ensure that the technique is implemented as per the reports/notifications/applications provided to applicable regulatory authorities [Section 8.7]. General • Confirm with the Inspector(s) that all notifications and approvals and/or letters of advice are in place prior to commencing instream construction at each water/canal crossing [Section 8.7]. • Grade away from watercourses to reduce the risk of introduction of soil and organic debris. Do not place windrowed or fill material in watercourses during grading [Section 8.2]. • Install a temporary sediment barrier (*e.g.,* sediment fences), where warranted, to eliminate the flow of sediment from spoil piles and disturbed areas into nearby waterbodies [Section 8.7]. • Inspect temporary sediment control structures (*e.g.,* sediment fences, subsoil berms) installed on approach slopes, on a daily basis throughout crossing construction. Repair the structures, if warranted, before the end of the working day [Section 8.7]. • Develop water quality monitoring plans, where required, to monitor for sediment events during select isolated trenched crossings of watercourses with high sensitivity fish habitat, or open-cut crossing construction activities where flow is present. If monitoring reveals that sediment values are approaching threshold values, the water quality monitors will notify the Lead Environmental Inspector and Inspector(s) who, with the Construction Manager and contractor, will develop corrective actions [Section 8.7].	• Reduction in surface water quality due to suspended sediment during instream activities at trenched crossings during construction and site-specific maintenance activities.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.2 Suspended sediment concentrations in the water column during instream activities (cont'd)	All	LSA	Open Cut Crossing Technique • Conduct an open cut crossing of seasonally dry or frozen to the bottom watercourses in Alberta in accordance with the Alberta *Operational Statement for Isolated or Dry Open-cut Stream Crossings* (see Watercourse Crossing – Open Cut Method for Dry/Frozen Watercourses Drawing in Appendix R of the Pipeline EPP) [Section 8.7]. Isolation Crossing Technique • Construct the crossing in accordance with the COP (Alberta only) requirements and in accordance with the conditions of the DFO's Operational Statement for *Isolated or Dry Open-cut Stream Crossings*, letter of advice or other DFO conditions. In BC, isolated pipeline crossings are not included under the Pacific Region DFO's *Operational Statement for Isolated or Dry Open-cut Crossings* [Section 8.7]. • Dewater the segment of the watercourse between the dams, if feasible and safe to do so. Pump any silt-laden water out between the dams to well-vegetated lands, away from the watercourse or to settling ponds [Section 8.7]. • Remove any accumulations of sediment within the isolation areas that resulted from crossing construction. Spread all sediment and unused trench spoil removed from the watercourse at a location above the high water mark where the materials will not directly re-enter the watercourse [Section 8.7]. • Install sack trench breakers back from the edge of watercourses where the banks consist of organic material to prevent sloughing of backfill into the channel (see Trench Breaker – Watercourse / Wetland Drawing in Appendix R of the Pipeline EPP) [Section 8.7]. • Ensure that water from flumes, dam and pumps, diversion or other methods does not cause erosion or introduce sediment into the channel. If warranted, place rock rip rap, tarpaulins, plywood sheeting or other materials to control erosion at the outlet of pump hoses and flumes. Supplement the erosion control materials, if warranted, to control any erosion [Section 8.7]. Vehicle Crossings General • Use the vehicle crossings at watercourses crossed by access roads identified in Section 9.0 of the Pipeline EPP and within the aquatic resources tables [Appendix I] and on the Environmental Alignment Sheets [Section 8.7]. • Ensure that upgraded or new construction vehicle crossing structures are appropriate for the watercourse approaches, channel width and configuration, anticipated streamflows during the period of use, planned vehicle loads, and overall period/duration of use [Section 8.7]. Temporary Bridges • Install temporary bridges at locations identified in the environmental resource-specific mitigation tables for aquatic resources provided in Appendix I of the Pipeline EPP. Ensure bridges are clean prior to installation and dispose of soil at an appropriate location (see Vehicle Crossing – Typical Ramp and Culvert Drawing in Appendix R of the Pipeline EPP) [Section 8.7]. • Implement erosion control measures as soon as disturbance of the vegetation mat occurs [Section 8.7]. • Ensure stormwater from the bridge deck, side slopes and bridge approaches is directed away from the watercourse onto a well vegetated area [Section 8.7].	• See above.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.2 Suspended sediment concentrations in the water column during instream activities (cont'd)	All	LSA	• Stabilize and revegetate areas disturbed during installation and removal of a bridge; install erosion control measures, where warranted, to control surface erosion until vegetation is established [Section 8.7]. Temporary Fords • Ensure the use of a ford is a one-time crossing (over and back) or limit ford to a seasonally dry streambed [Section 8.7]. • Confine the use of fords to watercourses or segments of watercourses with low, stable banks and a stable substrate composed of materials such as gravel and bedrock. Trans Mountain will not grade the banks to create a ford [Section 8.7]. • Install matting, where warranted, to protect the bed and banks of a watercourse to be forded [Section 8.7]. Ice Bridges/Snow Fills • Install clean snowfills during frozen conditions at locations identified in the environmental resource-specific mitigation tables for aquatic resources provided in Appendix I of the Pipeline EPP and at all minor and intermittent watercourses [Section 8.7]. • Install ice bridges at locations identified in the aquatic resources tables during frozen soil conditions (see Appendix I of the Pipeline EPP) [Section 8.7]. • Design, construct and abandon ice bridge and snow fill vehicle crossings at watercourses in accordance with the DFO *Operational Statement for Ice Bridges and Snow Fills* [Section 8.7]. • See recommended mitigation measures outlined in Table 7.2.7-2 Fish and Fish Habitat and Section 8.7 of the Pipeline EPP for additional measures. Operations • Implement measures similar to construction under direction of Trans Mountain's Environmental, Health and Safety Management System to reduce suspended sediment released during integrity digs conducted instream.	• See above.
1.3 Erosion from approach slopes	All	LSA	Pipeline Crossings • Prohibit clearing of extra temporary workspace within the riparian buffer, only the trench and temporary workspace areas will be cleared. Ensure staging areas for watercourse crossing construction and spoil storage areas are located a minimum of 10 m from the banks of watercourse boundaries. This distance may be reduced by the Lead Environmental Inspector and the Inspector(s) where appropriate controls are in place and where no riparian area is present (*e.g.,* cultivated or disturbed lands that abut the watercourse banks) [Section 8.1]. • Restrict root grubbing to the area outside of the vegetated riparian buffer adjacent to watercourses [Section 8.1]. See additional root grubbing measures in Section 8.1 of the Pipeline EPP. • Install erosion control measures, where warranted, prior to commencing grading in the vicinity of water crossings [Section 8.2]. • Grade away from watercourses to reduce the risk of introduction of soil and organic debris. Do not place windrowed or fill material in watercourses during grading [Section 8.2].	• Reduction in surface water quality due to erosion from banks and approach slopes.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.3 Erosion from approach slopes (cont'd)	All	LSA	• Install temporary berms on approach slopes to watercourses and erect sediment fence(s) near the base of approach slopes to watercourse(s) following grading (see Cross Ditches and Diversion Berms and Sediment Fence Drawings provided in Appendix R of the Pipeline EPP) where indicated in the Environmental Alignment Sheets (Volume 6E). Inspect the temporary sediment control structures on a daily basis and repair, if warranted, before the end of each working day [Section 8.2]. • Install sack trench breakers back from the edge of watercourses where the banks consist of organic material to prevent sloughing of backfill into the channel (see Trench Breaker – Watercourse / Wetland Drawing in Appendix R of the Pipeline EPP) [Section 8.4]. • Install temporary erosion and sediment control structures (*e.g.,* sediment fences, coir logs) immediately following the completion of backfilling lands adjacent to watercourse crossings where the potential for sedimentation of the watercourse exists (see Sediment Fence and Coir/Straw Log Installation Drawings provided in Appendix R of the Pipeline EPP) [Section 8.4]. • See Appendix R of the Pipeline EPP for additional measures related to riprap armouring, vegetated soil wraps or cribwalls, and coir or other biodegradable erosion control fabric. • Seed riparian areas with an approved annual or perennial grass cover crop or native grass mix as soon as is feasible after construction. See additional measures outlined in the Reclamation Management Plan [Appendix C and Section 8.6]. • Transplant dormant shrubs, or install dormant willow stakes or commercially grown rooted stock plants (plugs), where warranted, during reclamation of streambanks where riparian vegetation is present prior to construction. See additional measures outlined in the Reclamation Management Plan [Appendix C] and aquatic resources tables [Appendix I and Section 8.6]. • Install permanent erosion control measures, as outlined in the Reclamation Management Plan [Appendix C] unless otherwise approved by Trans Mountain to adjust for site conditions and suitability [Section 8.6]. • Install temporary fencing, if warranted, to allow the revegetation treatments to become established and avoid damage to the banks and riparian area by wildlife/livestock [Section 8.7]. • Monitor watercourse after construction as outlined in Section 9.0 of Volume 6A to assess the success of construction and reclamation mitigation measures following the temporary disturbance. Implement remedial measures, where warranted. <u>Vehicle Crossings</u> • Ensure that equipment used during construction of the vehicle crossings is used in a manner that reduces disturbance of the bed and banks and ensure bridge installation does not alter the stream bed or banks or require infilling of the channel [Section 8.7]. • Seed disturbed areas on the banks and approaches as soon as practical with an approved grass cover crop species or native grass seed mix and implement sediment control measures to stabilize watercourse banks and prevent sedimentation of the watercourse, respectively. Follow measures provided in the Reclamation Management Plan [Appendix C and Section 8.7].	• See above.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.3 Erosion from approach slopes (cont'd)	See above	See above	<u>Operations</u> • Implement measures similar to construction under direction of Trans Mountain's Environmental, Health and Safety Management System for controlling erosion from banks and approach slopes during integrity digs conducted instream or in vicinity to watercourses.	• See above.
1.4 Inadvertent instream drilling mud release	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	LSA	• Plan for and use the procedures for a HDD or other trenchless crossing in accordance with those provided in the Horizontal Directional Drilling/Trenchless Planning and Procedures Management Plan [Appendix C and Section 8.7]. • Cease trenchless crossing work immediately and refer to the Drilling Mud Release Contingency Plan [Appendix B] in the event that an inadvertent release of drilling mud has occurred and the material is or may enter the watercourse or affect other sensitive environmental or land use features [Section 8.7]. • Assign Inspector(s), QAES or QEP with expertise in the containment of inadvertent release of drilling mud and clean up to HDDs under a watercourse (see Drilling Mud Release Contingency Plan in Appendix B of the Pipeline EPP) [Section 8.7]. • Follow the drilling mud frac-out monitoring and other measures outlined in the Drilling Mud Release Contingency Plan [Appendix B] during horizontal directional drilling [Section 8.7]. • Monitor to assess the immediate effects of crossing construction, if warranted. Also monitor sediment release (*i.e.*, turbidity and TSS) throughout the crossing construction period, if required [Section 8.7].	Reduction in surface water quality due to an inadvertent drilling mud release during HDD crossings.
1.5 Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water	Edmonton to Hinton North Saskatchewan River Pembina River McLeod River Hargreaves to Darfield Fraser River Canoe River North Thompson River Black Pines to Hope Thompson River Coldwater River Coquihalla River Hope to Burnaby Coquihalla River Sumas River Fraser River Burnaby to Westridge Fraser River	LSA	• Conduct hydrostatic testing activities in accordance with the *NEB OPR*, provincial legislation, Transport Canada's *Minor Works for Water Intakes* as well as the latest version of Canadian Standards Association (CSA) Z662 and the *Oil and Gas Waste Regulation* Section 7(2)(e), BC Reg. 254/2005 [Section 8.5]. • Follow the mitigation measures related to water withdrawal and dewatering provided in the Water Withdrawal and Discharge Procedures Management Plan [Appendix C] during hydrostatic testing [Sections 8.5]. • Collect samples of source water, hydrostatic test water and soil of the receiving environment and analyze according to the parameters listed in Water Withdrawal and Discharge Procedures Management Plan [Appendix C] [Section 8.5]. • Employ sediment reduction methods (*e.g.,* sediment mat, sediment fence, sand bag, coffer dam), where warranted, to prevent increased sedimentation or reduced water quality [Section 8.5]. • Isolate test pumps, generators and fuel storage tanks with an impermeable lined dike or depression to capture and retain any spills of fuels or lubricants [Section 8.5]. • See additional measures related to hydrostatic testing, including the use of chemical additives and erosion control, in Section 8.5 of the Pipeline EPP. • See Section 7.2.2 Soil and Soil Productivity for discussion on the release of hydrostatic test water on land. • See Section 7.2.4 Human Occupancy and Resource Use of Volume 5B for discussion on potential effect of withdrawal of hydrostatic test water on downstream water users.	• Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water.
