1.6 Reduction of surface water quality due to small spill during construction or site-specific maintenance activities	All	LSA	• Ensure the following separation distances are maintained between a watercourse when planning and constructing the pipeline, unless otherwise approved: • fuel or hazardous material storage site - 300 m; • burning site - 100 m; and • oil change area - 100 m [Section 7.0]. • See Section 7.0 of the Pipeline EPP for additional measures for hazardous materials storage, servicing vehicles and spill equipment needs as well as cleaning of equipment. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are dumped on the ground or into waterbodies. In the event of a spill, implement the Spill Contingency Plan [Appendix B] [Section 7.0]. • Conduct refuelling a minimum of 100 m from any watercourse unless otherwise approved by the appropriate regulatory authority [Section 7.0]. See additional measures for refuelling near waterbodies in Section 7.0 of the Pipeline EPP.	• Contamination of surface water due to a small spill during construction or site-specific maintenance activities.
2. Water Quality and Quantity Indicator – Surface Water Quantity				
2.1 Alteration of natural surface drainage patterns	All	LSA	• Maintain drainage across the construction right-of-way during all phases of construction [Section 7.0]. • Ensure the potential for soil erosion by water is reduced during construction activities by avoiding ponding of water or the unintentional channelization of surface water flow [Section 7.0]. • Provide surface drainage of adequate capacity across the construction right-of-way [Section 7.0]. • Locate gaps in pipe, snow, topsoil/root zone material and spoil at watercourse crossings [Section 8.2]. • Reduce grading along the construction right-of-way and associated facilities, especially within watercourse/wetland/lake vegetated buffers [Section 8.2]. • Leave hard plugs or install soft plugs at locations where the open trench could dewater a wetland or flood other areas [Section 8.3]. • Leave breaks in the trench crown at obvious drainages and wherever seepage occurs to reduce or avoid interference with natural drainage [Section 8.4]. • Recontour the construction right-of-way and stabilize approach slopes at watercourse crossings. Where reclamation of the pre-construction grade is not feasible due to risk of failure of fill on slopes or maintenance of an access trail, recontour to grades as directed by the Geotechnical Engineer [Section 8.6]. • Regrade areas with vehicle ruts, erosion gullies or where the trench has settled [Section 8.6]. • Implement similar mitigation measures during site-specific maintenance activities during operations. • See recommended mitigation measures outlined in Table 7.2.8-2 Wetland Loss or Alteration.	• Localized alteration of natural surface drainage patterns until trench settlement is complete.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.2 Instability of trench at locations with high water table	All	LSA	• Limit the length of open trench and the time the trench will be left open to reduce the amount of trench sloughing [Section 8.3]. • Suspend trenching and salvage a wider area of topsoil/root zone material if the trench walls slough into the trench and the potential for topsoil/root zone material/subsoil mixing exists. Back slope the trench walls until stable. Equip backhoe with a swamp bucket, if practical, to avoid or reduce trench sloughing [Section 8.3]. • Delay trenching until immediately prior to lowering-in at locations with a high water table or where there is a risk of sloughing [Section 8.3]. • Assess the need for well points or other dewatering methods, prior to commencing trenching, to intercept groundwater at site-specific locations before it enters the trench [Section 8.3]. • See potential effect 1.1 of this table for mitigation related to dewatering trench. • See recommended mitigation measures outlined in Table 7.2.8-2 Wetland Loss or Alteration.	• No residual effect identified.
2.3 Disruption or alteration of streamflow	All	LSA	• Adhere to clearing guidelines for protection of streams and wetlands provided in AESRD's guidelines and the Forest Practices Code, Riparian Management Area Guidebook in BC, where riparian management zones (widths) are identified based on stream or wetland class [Section 8.1]. • Fell trees away from watercourses and away from limits of the construction right-of-way to reduce damage to streambanks, beds and adjacent trees. Hand clear the area, if necessary, to reduce disturbance. Any trees, debris and soil inadvertently deposited within the ordinary high watermark will be promptly removed in a manner that avoids or reduces disturbance of the bed and banks. Trees will not be stood or hauled across watercourses [Section 8.1]. • Do not place windrowed or fill material in watercourses during grading [Section 8.2]. • Remove bar ditch ramps to prevent blockage of spring runoff in road ditches unless culverts were installed during surface preparation activities [Section 8.6]. • Re-establish streambanks and approaches immediately following construction of water crossings as outlined in the Reclamation Management Plan [Appendix C] [Section 8.6]. • Ensure that upgraded or new construction vehicle crossing structures are appropriate for the watercourse approaches, channel width and configuration, anticipated streamflows during the period of use, planned vehicle loads, and overall period/duration of use [Section 8.7]. • Ensure streamflow, if present, is maintained under ice bridge and snow fill vehicle crossings [Section 8.7]. • Ensure streamflow, if present, is maintained at all times when trenching through a watercourse [Section 8.7]. • Disruption of streamflow due to the withdrawal of hydrostatic test water is addressed in potential effect 1.5 of this table. • Disruption of streamflow and the potential effect on navigability of waterbodies are addressed in Section 7.2.6 Navigation and Navigation Safety of Volume 5B.	• Disruption and alteration of natural streamflow from instream activities.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.4 Alteration of streamflow volumes as a result of withdrawal and release of hydrostatic test water	**Edmonton to Hinton** North Saskatchewan River Pembina River McLeod River **Hargreaves to Darfield** Fraser River Canoe River North Thompson River **Black Pines to Hope** Thompson River Coldwater River Coquihalla River **Hope to Burnaby** Coquihalla River Sumas River Fraser River **Burnaby to Westridge** Fraser River	LSA	• Determine which applicable regulatory authority approvals are necessary for water withdrawal and discharge to allow for hydrostatic testing of the pipeline and to ensure conditions of approvals are satisfied during water withdrawal for hydrostatic testing [Section 8.5]. • Conduct hydrostatic testing activities in accordance with the *NEB OPR*, provincial legislation, Transport Canada's *Minor Works for Water Intakes* as well as the latest version of CSA Z662 and the *Oil and Gas Waste Regulation* Section 7(2)(e), BC Reg. 254/2005 [Section 8.5]. • The withdrawal rate and volume will not exceed 10% of the flow rate of the watercourse or of the volume of the body of water unless otherwise approved by the appropriate authority when withdrawing water in Alberta [Section 8.5]. • Ensure the water level in a lake does not fall more than 10 cm once water withdrawal has started if the *Water Act* approval requires this. Retain a copy of the water withdrawal approval/permit onsite and ensure the Inspector(s) has reviewed the water withdrawal approval/permit prior to the commencement of withdrawal activities [Section 8.5]. • Terminate or reduce the rate of water withdrawal if the approved minimum flow or depth of water in the source waterbody is reached during a water withdrawal, unless otherwise approved by the appropriate regulatory authority. Resume or increase the rate of water withdrawal only when flows or water levels exceed approved minimum values [Section 8.5]. • Discharge locations will be preferentially selected to dewater onto stable terrain areas rather than directly into a watercourse/wetland/lake where the water will be filtered through vegetation and soils prior to returning to a watercourse/wetland/lake [Section 8.5].	• No residual effect identified.
3. Water Quality and Quantity Indicator – Groundwater Quality				
3.1 Shallow groundwater with existing contamination encountered during trench construction	All, but predominantly urban areas **Black Pines to Hope** RK 844.8 to RK 845.8	LSA	• Ensure an environmental monitor with experience in contaminated sites is present to check for indications of potential groundwater contamination (*i.e.*, sheen, odour, adjacent soil staining) during pipeline trench excavation in areas where there is higher potential for encountering contamination (*e.g.*, urban areas). Where groundwater contamination is suspected the groundwater should be sampled and analyzed by an accredited laboratory [Section 8.3]. • Ensure contaminated soil and water are not transported off-site or disposed until analytical results have been received as per federal and provincial legislation. The Construction Manager and Inspector(s) will provide notification as to when excavations can be backfilled [Section 8.3]. • Notify and adhere to the advice of the Trans Mountain Environment, Health and Safety Department or Trans Mountain's Lead Environmental Inspector and Inspector(s) at locations where water potentially contaminated with hydrocarbons or other materials is to be discharged from the trench. Measures may include the use of tank trucks to haul discharged water to an appropriate disposal facility/site, ensuring the intake is submerged below the surface sheen, lab testing and use of sorbent booms to hold the sheen away from the pump intake [Section 8.3].	• No residual effect identified.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.2 Areas susceptible to drilling mud release during trenchless crossing construction	All	LSA	• Conduct investigations prior to the commencement of drilling activities to assess groundwater conditions and risks (water supply wells within LSA) in highly vulnerable aquifers. Modify the drill path of the horizontal directional drill, if feasible, to reduce the potential effects on groundwater quality and, if warranted, monitor water supply wells in the immediate area before, during and after the horizontal directional drill. Have plans in place for the supply of alternate water in the event that water quality in the wells is affected [Section 8.7]. • Plan for and use the procedures for a HDD or other trenchless crossing in accordance with those provided in the Horizontal Directional Drilling/Trenchless Planning and Procedures Management Plan (see Appendix C) [Section 8.7]. • Ensure that drilling mud composition is limited to bentonite mud drilling systems, fresh water and, if warranted, other inert additives [Appendix B]. • Cease trenchless crossing work immediately and refer to the Drilling Mud Release Contingency Plan (see Appendix B) in the event that an inadvertent release of drilling mud has occurred and the material is entering or may enter the watercourse or affect other sensitive environmental or land use features [Section 8.7]. • Follow the drilling mud frac-out monitoring and other measures outlined in the Drilling Mud Release Contingency Plan (see Appendix B) during horizontal directional drilling [Section 8.7].	• Elevated turbidity in groundwater as a result of accidental drilling mud release.
3.3 Areas susceptible to sedimentation in the aquifer	All	LSA	• Assess the grain size; if it is poorly graded and coarse material, the installation of filter fabric at the base of the trench to prevent migration of fine sediment into the aquifer during trenching over highly vulnerable aquifers.	• Elevated turbidity in groundwater as a result of sedimentation.
3.4 Areas susceptible to blasting effects	All	LSA	• Notify landowners with water supply wells within the Water Quality and Quantity LSA before blasting is carried out and conduct investigations, where warranted, to assess groundwater conditions and risks [Section 6.0]. • Initiate pre-construction monitoring, where warranted, prior to the commencement of a specific activity during construction (*e.g.*, blasting). Monitoring may be necessary prior to, during and following construction or a specific construction activity in the vicinity of water wells or springs [Section 6.0]. • During Project field studies, the Hydrogeological Engineer in consultation with landowners and the appropriate regulatory authorities will determine if springs and wells used for domestic purposes located in the immediate vicinity of the construction right-of-way will be sampled for water quality and flow rate prior to the start of construction. Locate and flag or fence registered or known water wells in the immediate vicinity of the construction right-of-way [Section 6.0]. • Monitor all registered or known potable water wells located within 200 m of any blasting prior to and following blasting. Monitoring will include measurement of well yields, static and pumping water levels as well as water sampling in accordance with Canadian Guidelines for Drinking Water Quality (Health Canada 2012) [Section 8.3]. • Re-establish or replace a potable water supply as required should a registered or known water well located within 30 m of the construction right-of-way be damaged (*i.e.*, diminishment in quantity and/or quality) during pipeline installation [Section 7.0].	• Elevated turbidity in groundwater as a result of silt release during blasting.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.5 Areas with potential artesian conditions	All	LSA	• Ensure that surficial materials are hydraulically isolated before drilling to deeper depths. • Use current drilling technology to ensure mud or casing seal is effective. • Depressurize the aquifer in the vicinity of the HDD area during the subsurface crossing and casing installation operations. • Seal/cement annular space around pipeline [Section 8.3]. • Abandon boreholes upon completion of the HDD.	• Groundwater from different aquifers may be mixed.
3.6 Aquifers (including unconfined aquifers) or wells vulnerable to possible future contamination from a spill during construction	All segments for wells Unconfined aquifers: Hope to Burnaby RK 1042.2 to RK 1043.3 RK 1047.6 RK 1049.3 to RK 1051.6 RK 1054.6 to RK 1062.8 RK 1062.8 to RK 1065.1 RK 1077.3 to RK 1089.9 RK 1080.1 to RK 1083.1 RK 1089.9 to RK 1094.2 RK 1094.2 to RK 1094.9 RK 1094.9 to RK 1097.9 RK 1097.9 to RK 1101.1 RK 1101.2 to RK 1104.7 RK 1104.7 to RK 1107.5	LSA	• Utilize Best Management Practices for spill prevention outlined in the Pipeline EPP including in areas where higher vulnerability wells and aquifers are identified. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are dumped on the ground or into waterbodies. In the event of a spill, implement the Spill Contingency Plan (see Appendix B) [Section 7.0]. • Re-establish or replace a potable water supply as required should a registered or known water well located within 30 m of the construction right-of-way be damaged (*i.e.*, diminishment in quantity and/or quality) during pipeline installation [Section 7.0].	• Contamination of aquifer as a result of a spill during construction.
4. Water Quality and Quantity Indicator – Groundwater Quantity				
4.1 Areas susceptible to changes in groundwater flow patterns	All	LSA	• Monitor water encountered in the trench during trenching to determine if groundwater flow is being intercepted. If spring flow has been disrupted, seek and follow the advice of the Hydrogeological or Geotechnical Resource Specialist to maintain cross drainage within the trench (*e.g.*, installation of subdrains, trench breakers) [Section 8.3]. • Assess the need for well points or other dewatering methods, prior to commencing trenching, to intercept groundwater at site-specific locations before it enters the trench [Section 8.3]. • Prevent the pipeline trench and bedding from becoming a conduit for increased groundwater flow. • Install trench breakers to force groundwater seepage along the pipeline trench to the surface, if springs are encountered along the route. Install subdrains, if warranted, to divert shallow groundwater flow from the right-of-way [Section 8.4]. • Install trench breakers, where warranted, at the edge of perched wetlands to prevent the pipeline trench from acting as a drain (see Trench Breaker – Watercourse/Wetland Drawing in Appendix R) [Section 8.4].	• Natural groundwater pathways may be bisected and create a sink (drain) for shallow groundwater. • Flooding on the up-gradient side of the pipeline may result in creation of wet zones on ground surface. • Reduction of baseflow to local streams.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
4.1 Areas susceptible to changes in groundwater flow patterns (cont'd)	All	LSA	• Install subdrains in association with trench breakers as directed by Trans Mountain's Engineer where there is evidence of seepage or a flowing spring on a slope once the trench is excavated (see Subdrains Drawing in Appendix R) [Section 8.4]. • Backfill clay/mineral soil first, if salvaged separately from organic material in shallow peatland areas, to ensure that cross drainage is maintained [Section 8.4]. • Ensure that the lower lift of subsoil is backfilled before the upper lift of subsoil where three lift soil handling has been conducted [Section 8.4].	• See above.
4.2 Disruption of shallow groundwater in high permeable materials in proximity to rivers or watercourse crossings with fluvial materials or colluvium in the substrate	Edmonton to Hinton RK 24.1 to RK 24.4 RK 28 to RK 28.2 RK 34.4 to RK 34.6 RK 36.8 to RK 37.1 RK 134.9 to RK 135.6 RK 185.3 RK 220.6 RK 223.7 to RK 224.1 RK 224.7 to RK 225 RK 309.1 to RK 311.1 RK 319.8 to RK 320.1 RK 327.5 to RK 327.7 RK 337.2 to RK 337.5 Hargreaves to Darfield RK 559 RK 559 RK 592.9 to RK 593 RK 619.9 RK 621 to RK 622.9 RK 622.9 to RK 625.4 RK 625.4 to RK 626.9 RK 642 to RK 643.5 RK 645.3 to RK 645.8 RK 646.8 to RK 648.2 RK 649 RK 651.3 to RK 651.8 RK 659.8 to RK 660.7 RK 668.4 to RK 668.9 RK 669 to RK 671.2 RK 682.8 to RK 684.2 RK 515.9 RK 715.6 RK 734.9 to RK 735.1 RK 740.7 to RK 740.8 RK 581.1 RK 600.2 to RK 600.3 RK 613.8 Black Pines to Hope RK 927.8 to RK 928 RK 970.2 to RK 970.3 RK 980 to RK 980.1 RK 1021.8 RK 1026.5	LSA	• See recommended mitigation measures outlined in potential effect 4.1 of this table.	• Natural groundwater pathways may be bisected and create a sink (drain) for shallow groundwater. • Reduction of baseflow to local streams.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
4.3 Disruption of groundwater flow where springs are encountered	Edmonton to Hinton RK 327.5 to RK 327.7	LSA	• Monitor water encountered in the trench during trenching to determine if groundwater flow is being intercepted. If spring flow has been disrupted, seek and follow the advice of the Hydrogeological or Geotechnical Resource Specialist to maintain cross drainage within the trench (*e.g.*, installation of subdrains, trench breakers) [Section 8.3]. • Assess the need for well points or other dewatering methods, prior to commencing trenching, to intercept groundwater at site-specific locations before it enters the trench [Section 8.3]. • Install trench breakers to force groundwater seepage along the pipeline trench to the surface, if springs are encountered along the route. Install subdrains if warranted, to divert shallow groundwater flow from the right-of-way [Section 8.4].	• Natural groundwater pathways may be bisected and create a sink (drain) for shallow groundwater.
4.4 Areas where dewatering may be necessary during pipeline construction activities	All	LSA	• Dewater the trench, if warranted, when laying pipe in areas with high water tables. Place pumps on a tray or within an excavated sump lined with polyethylene sheeting above the ordinary high water level of the watercourse/wetland/lake. Pump water onto stable and well vegetated areas, tarpaulins or sheeting at least 50 m from the nearest waterbody in a manner that does not cause erosion or any unfiltered or silted water to re enter a watercourse [Section 8.3]. See additional dewatering measures in Section 8.3 of the Pipeline EPP. • Use floating suction hose and elevated intake, or other measures approved by Trans Mountain's Inspector(s), to prevent sediment from being sucked from the bottom of the trench. Secure the pump intake a minimum of 30 cm above the bottom of the trench [Section 8.3].	• Change in natural groundwater levels and stream recharge due to the discharge of groundwater to surface water systems if not practical to discharge trench water to ground.
4.5 Disruption of groundwater flow where shallow groundwater is encountered	Hargreaves to Darfield RK 522.6 RK 531.2 RK 533 RK 545.8 to RK 545.9 RK 613.7 RK 638.7 Black Pines to Hope RK 846.5 to RK 847.5 RK 858.3 to RK 858.5 RK 869.7 to RK 870.1 RK 881.7 RK 957.8 to RK 957.9 RK 963.1 to RK 963.6 RK 1021.8 RK 1022.9 RK 1028.6 to RK 1028.7 RK 1032.6	LSA	• See recommended mitigation measures outlined in potential effects 4.1 and 4.4 of this table.	• Natural groundwater pathways may be bisected and create a sink (drain) for shallow groundwater. • Change in natural groundwater levels and stream recharge due to the discharge of groundwater to surface water systems if not practical to discharge trench water to ground.
4.6 Areas with potential artesian conditions, including deeply incised creek crossings	All	LSA	• Depressurize the construction area or subsurface crossing area prior to excavation/directional drilling through, for example, drilling wells and then extracting water in order to reduce locally, the pressure in the aquifer. • Re-create the confining layers if disturbed during construction (*e.g.*, place seal/cement in annular space around pipeline).	• Flooding from artesian flow may occur during trenchless crossing installation.

TABLE 7.2.3-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
4.6 Areas with potential artesian conditions, including deeply incised creek crossings (cont'd)	Deeply incised creek crossings include: Hargreaves to Darfield RK 514.4 RK 515.9 RK 517.8 RK 523.6 RK 534.4 RK 573.5 RK 576.3 RK 590.3 RK 611.7 to RK 611.8 RK 626.6 RK 663.2 to RK 663.5 RK 910.1 RK 561.2 RK 563.4 to RK 563.5 RK 565.9 RK 567.6 RK 571.9 RK 580.3 RK 634	LSA	• Understand hydrogeological and geotechnical conditions, and assess the risks before commencing a trenchless crossing. Complete a trenchless crossing alignment site reconnaissance, supported, where warranted, by a drilling and testing program designed to confirm hydrogeological and geotechnical conditions. Design the trenchless crossing and pipeline installation to prevent damage caused by artesian flow.	• See above.
4.7 Areas of shallow groundwater susceptible to blasting effects	All	LSA	• See recommended mitigation measures for blasting outlined in potential effect 3.4 of this table.	• Reduction of water quantity if blasting damages the well or the surrounding formation. • Enhancement of water quantity if blasting opens or unclogs fractures supplying existing water well.
4.8 Impacts to shallow wells	Edmonton to Hinton RK 39.6 RK 41.6 RK 50.9 RK 56.9 RK 89.2 RK 90.2 RK 171.4 to RK 171.5 RK 329.5 RK 17.9 Hargreaves to Darfield RK 706 RK 711.5 RK 713.4 RK 717.5 RK 725.6 to RK 725.7 RK 728.8 to RK 729.5 RK 731 to RK 731.6 Black Pines to Hope RK 956.2 RK 1040.1 RK 1040.6 Hope to Burnaby RK 1057.6 RK 1147.4 RK 1159	LSA	• Initiate pre construction monitoring, where warranted, prior to the commencement of a specific activity during construction (*e.g.,* blasting). Monitoring may be necessary prior to, during and following construction or a specific construction activity in the vicinity of water wells or springs [Section 6.0]. During Project field studies, the Hydrogeological Engineer in consultation with landowners and the appropriate regulatory authorities will determine if springs and wells used for domestic purposes located within the immediate vicinity of the construction right-of-way will be sampled for water quality and flow rate prior to the start of construction. Locate and flag or fence registered or known water wells in the immediate vicinity of the construction right-of-way [Section 6.0]. • During construction, avoid blasting in proximity to wells. • Monitor all registered or known potable water wells located within 200 m of any blasting prior to and following blasting. Monitoring will include measurement of well yields, static and pumping water levels as well as water sampling in accordance with Canadian Guidelines for Drinking Water Quality [Section 8.3]. • Re-establish or replace a potable water supply as required should a registered or known water well located within 30 m of the construction right-of-way be damaged (*i.e.*, diminishment in quantity and/or quality) during pipeline installation [Section 7.0].	• No residual effects identified for shallow wells outside of blasting areas. • Shallow wells within blasting areas: - Reduction of water quantity if blasting damages the well or the surrounding formation. - Enhancement of water quantity if blasting opens or unclogs fractures supplying existing water well.

Notes: 1 LSA = Water Quality and Quantity LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.2.3.5 Potential Residual Effects

The potential residual environmental effects on water quality and quantity indicators associated with the construction and operations of the pipeline (Table 7.2.3-2) are:

- reduction in surface water quality due to suspended sediments during instream activities at trenched crossings, erosion from banks and approach slopes, an inadvertent drilling mud release during HDD crossings or contamination from small spills during construction or site-specific maintenance activities;
- alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water;
- localized alteration of natural surface drainage patterns until trench settlement is complete;
- disruption and alteration of natural streamflow from instream activities;
- elevated turbidity in groundwater as a result of accidental drilling mud release, sedimentation or sediment release during blasting;
- groundwater from different aquifers may be mixed;
- contamination of aquifer as a result of a spill during construction;
- natural groundwater pathways may be bisected and create a sink (drain) for shallow groundwater;
- flooding on the up-gradient side of the pipeline may result in creation of wet zones on ground surface;
- reduction of base flow to local streams;
- change in natural groundwater levels and stream recharge due to the discharge of groundwater to surface water systems if not practical to discharge trench water to ground;
- flooding from artesian flow may occur during trenchless crossing installation;
- reduction of water quantity if blasting damages the well or the surrounding formation; and
- enhancement of water quantity if blasting opens or unclogs fractures supplying existing water well.

Some of the potential effects on water quality and quantity indicators associated with the construction and operations of the pipeline either do not apply or are predicted to be eliminated through the implementation of mitigation measures (Table 7.2.3-2). The potential effects determined not to have a residual effect are:

- instability of trench at locations with high water table;
- alteration of streamflow volumes as a result of withdrawal and release of hydrostatic test water; and
- shallow groundwater with existing contamination encountered during trench construction.

7.2.3.6 Significance Evaluation of Potential Residual Effects

Where there are no standards, guidelines, objectives or other established and accepted ecological thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method is considered to be the appropriate method for determining the significance of the anticipated residual environmental effects. Consequently, a qualitative assessment of water quality and quantity was determined to be the most appropriate method with the evaluation of significance of each of the potential residual effects relying on the professional judgment of the assessment team in consideration of CCME guidelines and provincial guidelines, where applicable.

Table 7.2.3-3 provides a summary of the significance evaluation for potential residual environmental effects of the construction and operations of the proposed pipeline on water quality and quantity. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.3-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON WATER QUALITY AND QUANTITY

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Water Quality and Quantity Indicator – Surface Water Quality									
1(a)	Reduction in surface water quality due to suspended sediment during instream activities at trenched crossings during construction or site-specific maintenance activities.	Negative	LSA	Immediate to short-term	Isolated to occasional	Immediate to short-term	Low	High	High	Not significant
1(b)	Reduction in surface water quality due to erosion from banks and approach slopes.	Negative	LSA	Immediate to short-term	Isolated to occasional	Short to medium-term	Low to medium	High	High	Not significant
1(c)	Reduction in surface water quality due to an inadvertent drilling mud release during HDD crossings.	Negative	LSA	Immediate to short-term	Accidental	Immediate to short-term	Low to medium	Low	Moderate	Not significant
1(d)	Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water.	Negative	LSA	Short-term	Isolated	Immediate to short-term	Low	Low	High	Not significant
1(e)	Contamination of surface water due to a small spill during construction or site-specific maintenance activities.	Negative	LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
1(f)	Combined effects on the surface water quality indicator (1[a] and 1[b]).	Negative	LSA	Short-term	Isolated to occasional	Immediate to medium-term	Low to medium	High	High	Not significant
2.	Water Quality and Quantity Indicator – Surface Water Quantity									
2(a)	Localized alteration of natural surface drainage patterns until trench settlement is complete.	Negative	LSA	Short-term	Isolated to occasional	Short to medium-term	Low to medium	High	High	Not significant
2(b)	Disruption and alteration of natural streamflow from instream activities.	Negative	LSA	Immediate to short-term	Isolated to occasional	Short to medium-term	Low to medium	High	High	Not significant
2(c)	Combined effects on the surface water quantity indicator (2[a] and 2[b]).	Negative	LSA	Short-term	Isolated to occasional	Short to medium-term	Low to medium	High	High	Not significant
3.	Water Quality and Quantity Indicator – Groundwater Quality									
3(a)	Elevated turbidity in groundwater as a result of accidental drilling mud release, siltation or silt release during blasting.	Negative	LSA	Short-term	Accidental	Short-term	Medium	Low	Moderate	Not significant
3(b)	Groundwater from different aquifers may be mixed.	Negative	LSA	Short-term	Accidental	Medium-term	Low to high	Low	Moderate	Not significant
3(c)	Contamination of aquifer as a result of a spill.	Negative	LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
4.	Water Quality and Quantity Indicator – Groundwater Quantity									
4(a)	Natural groundwater pathways may be bisected and create a sink (drain) for shallow groundwater.	Negative	LSA	Short-term	Periodic	Short - term	Low	Low	Moderate	Not significant
4(b)	Flooding on the up-gradient side of the pipeline may result in the creation of wet zones on ground surface.	Negative	LSA	Short-term	Periodic	Short-term	Low	Low	Moderate	Not significant
4(c)	Reduction of base flow to local streams.	Negative	LSA	Short-term	Periodic	Short-term	Low	Low	Moderate	Not significant

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
4(d)	Change in natural groundwater levels and stream recharge due to the discharge of groundwater to surface water systems if not practical to discharge trench water to ground.	Negative	LSA	Short-term	Isolated	Short-term	Low	Low	Moderate	Not significant
4(e)	Flooding from artesian flow may occur and potentially impact trenchless crossing installation.	Negative	LSA	Immediate to short-term	Isolated	Short-term	Low to medium	Low	Moderate	Not significant
4(f)	Reduction of water quantity if blasting damages the well or the surrounding formation.	Negative	LSA	Immediate	Accidental	Short-term	Low to medium	Low	Moderate	Not significant
4(g)	Enhancement of water quantity if blasting opens or unclogs fractures supplying existing water well.	Negative	LSA	Immediate	Accidental	Short-term	Negligible	Low	Moderate	Not significant

Notes: 1 LSA = Water Quality and Quantity LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Water Quality and Quantity Indicator – Surface Water Quality

The following provides the evaluation of significance of potential residual effects on the surface water quality indicator.

Instream Construction at Trenched Crossings

Sediment runoff and increased turbidity/TSS from pipeline construction was a concern during many of the stakeholder engagement events for the Project (*e.g.,* Edmonton ESA Workshop, Clearwater Community Workshop, Hope Community Workshop and Burnaby Community Workshop). In addition, TEK participants voiced concerns over water quality impacts at many of the watercourses crossed by the proposed pipeline corridor, which would predominately result from temporary increases in sediment runoff and increased turbidity/TSS (as opposed to low probability contamination from spills during construction [refer to Contamination of Surface Water Due to Small Spills below] or operations [Volume 7]). The selection of appropriate watercourse crossing techniques designed to meet federal and provincial regulatory requirements, as well as implementation of erosion controls on the approaches to watercourse crossings and riparian revegetation, are likely to substantially reduce the potential for adverse effects on surface water quality at watercourses encountered along the proposed pipeline corridor. During construction of trenched crossings, or where an instream vehicle crossing is necessary, a minor and short-term sediment release is expected during installation and removal of the vehicle or pipeline crossing structures. Trenched crossings are considered to have a negative impact balance since sediment input can temporarily decrease surface water quality.

Turbidity/TSS guidelines have been established for instream activities. At the federal level, DFO (2000) discusses ‘levels of risk’ associated with increases in TSS concentration in watercourses and indicates increases of <100 mg/L above background present low risk to fish and their habitat, while an increase of 100-200 mg/L presents a moderate risk. An excess of 400 mg/L was an unacceptable risk, but duration of exposure also needs to be taken into account (also see Birtwell 1999). The CCME guideline value for protection of aquatic life from short-term (24 hour) exposure is no more than 25 mg/L above existing levels (CCME 2007). Aquatic resources are protected by ensuring that concentration of TSS does not exceed CCME (2007) guidelines. BC guidelines specify that induced turbidity may not exceed background by more than 8 NTU during any 24 hour period or by more than 2 nephelometric turbidity units (NTU) when the duration of sediment input is between 24 hours and 30 days. Where flow is naturally turbid, induced turbidity may not exceed background by more than 8 NTU at any time when background is between 8 and 80 NTU, or by 10% at any time when background is greater than 80 NTU (BC MWLAP 2004a). Alberta's guideline of no more than 10 mg/L TSS is based on chronic, or long-term, exposure to elevated suspended solids.

The results of post-construction environmental monitoring for the TMX Anchor Loop Project demonstrate that the water crossing methods and mitigation measures implemented were effective in avoiding or reducing sediment input during construction. A total of 49 watercourses were monitored for water quality throughout construction (including open cut crossings of the Athabasca, Fraser, Miette and Snaring rivers and a number of isolated crossings). For all but one monitored watercourse, turbidity events were short in duration, with levels returning to normal within 24 hours, and compliance with the project-specific EPP and DFO Authorization or Letters of Advice was maintained. A sediment plume was observed seeping from the east bank of a smaller watercourse (Rockingham Creek) three days after the crossing was completed. Water quality monitors were dispatched to the site and remedial measures were taken to effectively stop the sedimentation. DFO was notified of mitigation measures applied and that CCME guidelines had been exceeded for a period greater than 24 hours (TERA 2009a). No ramifications to water quality were observed during post-construction environmental monitoring as a result of the sediment plume.

Open cut crossings are typically only utilized when a watercourse is dry or frozen to the bottom at the time of construction. Under these conditions, sediment release is not expected to occur, however, where an HDD or isolated crossing technique is not feasible, an open cut or partial isolation technique may be required on flowing watercourses. Monitoring will be conducted at all flowing open cut crossings to document downstream turbidity and any exceedances of the relevant guidelines will be reported to the appropriate regulatory authorities.

When compared to the open cut technique, isolated crossing techniques reduce the amount of sediment introduced to flowing watercourses. During a completely isolated crossing by dam and pump or flume, a minor sediment release is expected during installation of the dams prior to the isolation and during removal of the downstream dam at the conclusion of the isolation. Recent evidence demonstrates that smaller watercourses that lack substantial subsurface flow can be readily isolated with minimal sediment introduction when proper design, construction and mitigation measures are applied (CAPP *et al*. 2005, Reid *et al.* 2002a). Consequently, it is anticipated that average TSS levels during instream construction at these sites will be below turbidity/TSS guidelines.

Partial isolation techniques by coffer dams or partial bypass may release more sediment than a completely isolated crossing, but are more effective than unrestricted open cut crossings in reducing instream sediment loads. For example, at one watercourse crossing during construction of the TMX Anchor Loop Project, upstream pumps were used to redirect a portion of the clean flows around the crossing site, thereby reducing the amount of sediment introduced into the watercourse (TERA 2009a).

Measures in Table 7.2.3-2 and the Pipeline EPP (Volume 6B), including continual monitoring of sediment release (*i.e.*, turbidity and TSS), will be implemented at all isolated and partially isolated watercourses during crossing design and construction to reduce the magnitude and duration of the sediment pulse.

Minor releases of sediment may be associated with use of the temporary vehicle crossings at trenched crossing locations. Although elevated suspended sediment concentrations may result from instream construction and vehicle crossing use, pulses of suspended solids are generally expected to settle out of the water column within the ZOI in a timeframe measuring from minutes to a few hours (*i.e.*, less than CCME's short-term guideline of 24 hours). Water quality monitoring will be used when activities occur that have the potential to cause events that may exceed the guidelines. Any exceedances of the relevant guidelines will be reported to the appropriate regulatory authorities.

Given that suspended sediments are expected to settle out of the water column within the ZOI in a timeframe measuring from minutes to a few hours (*i.e.*, less than CCME's short-term guideline of 24 hours), residual effects on the surface water quality indicator during trenched and temporary vehicle crossings are reversible in the immediate to short-term and of low magnitude (Table 7.2.3-3, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – suspended sediments released during construction activities will be carried downstream until they disperse and/or naturally settle out within the predicted ZOI.

- Duration: immediate to short-term – the events causing the release of suspended sediments into surface water are instream construction or maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year during the operations phase.

- Frequency: isolated to occasional – the events causing the release of suspended sediments into a surface waterbody (*i.e.*, pipeline construction and maintenance activities) occur during construction and, for operations activities, intermittently and sporadically over the assessment period.

- Reversibility: immediate to short-term – an increase in suspended sediments is confined to a specific period not exceeding 24 hours after construction in flowing watercourses (*i.e.*, immediate) or the event when open cut crossings first become inundated with water (*i.e.*, short-term).

- Magnitude: low – an increase in suspended sediments is anticipated for a short timeframe and anticipated to be within CCME guidelines given the implementation of mitigation measures to reduce sedimentation.

- Probability: high – the proposed pipeline corridor crosses numerous watercourses for which a trenched crossing method is recommended during potentially flowing conditions at the time of construction.

- Confidence: high – based on available research literature, data pertinent to previous crossings along the existing TMPL right-of-way and the professional experience of the assessment team.

Erosion from Approach Slopes and Banks

Following grading, it is possible for some erosion to occur on approach slopes and banks and cause sedimentation of surface water. The impact balance of this potential residual effect is considered negative since sediment input could decrease surface water quality.

The results of the post-construction environmental monitoring program for the TMX Anchor Loop Project demonstrate that the water crossing methods and mitigation measures implemented were effective in avoiding or reducing erosion on the banks and approach slopes to watercourses (TERA 2009b, 2011a,b, 2013a). Most watercourse banks and slopes were stabilized and well-vegetated within 1 year of construction. During the first post-construction environmental monitoring year in 2009, bank erosion was observed at 3 of the 132 watercourses crossed by the pipeline. Remedial work was conducted and during post-construction environmental monitoring in 2010, two of the three watercourses required further remedial action (including seeding and replanting of riparian vegetation) (TERA 2011a). During post-construction environmental monitoring in 2012, no new erosion was observed and the two channels appeared stable and the current configuration appeared well-suited to the conveyance of seasonal flows (TERA 2013a). During the 2012 post-construction environmental monitoring program, however, erosion of watercourse banks was observed at three new watercourses, attributed to above average snow pack and spring freshet causing flooding of susceptible areas (TERA 2013a). At one of the watercourses, the effects on the restored right-of-way were consistent with the natural dynamics displayed by the channel. Nevertheless, restoration and restabilization of all three watercourses is planned and monitoring will continue until all erosion issues have been resolved (TERA 2013a). Mitigation measures used to control erosion and restabilize banks at trenched watercourse crossings for the TMX Anchor Loop Project are planned for trenched watercourse crossings along the pipeline segments associated with the Project.

During the Merritt Community Workshop, riparian restoration was noted as an important strategy for bank stabilization, particularly at smaller creeks vulnerable to seasonal high flows. Furthermore, at the same workshop, participants indicated the Nicola River in vicinity to the proposed pipeline crossing location is very sinuous and prone to changing course as a result of natural bank instability and riparian areas damaged by agricultural activities. Any further disturbance to the Nicola River will be avoided by implementing a trenchless (HDD) crossing technique. In the event an HDD is unsuccessful, an isolated open cut method will be used. Mitigation measures will be identified on a site-specific basis and may include, for example: installation of temporary erosion control structures (*e.g.,* sediment fences); restoration to stabilise the banks (*e.g.,* soil wraps, brush layers, willow plantings and matting); seeding the disturbed banks and approaches with the appropriate cover crop species and native grass mix; installation of coir or other biodegradable erosion control fabric on the banks of the watercourse;

installation of live dormant willow stakes or salvaged willow/shrub transplants or commercially grown rooted stock plugs in the banks of watercourses; and monitoring to assess the success of construction and reclamation mitigation measures and implementation remedial measures, where warranted (see the Pipeline EPP of Volume 6B).

Proposed mitigation measures are expected to reduce the magnitude of erosion from approach slopes and banks on the surface water quality indicator to low to medium levels. This residual effect is reversible in the short to medium-term (Table 7.2.3-3, point 1[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – any sedimentation caused by erosion will be carried downstream until it disperses and/or naturally settles out within the predicted ZOI.
- Duration: immediate to short-term – the events causing the erosion and sedimentation of surface water are instream construction or maintenance activities (*e.g.,* integrity digs), the latter of which are limited any 1 year during the operations phase.
- Frequency: isolated to occasional – the events resulting in sedimentation caused by erosion of approach slopes and banks (*i.e.*, pipeline construction and operations activities [*e.g.*, integrity digs]) occur intermittently and sporadically at unstable crossings until mitigated.
- Reversibility: short to medium-term – depending on the watercourse. For watercourses with gentle banks and approach slopes, vegetation may be re-established on the approach slopes and banks within 1 year of construction while revegetation of steeper approach slopes and banks may take longer than one growing season.
- Magnitude: low to medium – depending upon the amount of erosion that occurs.
- Probability: high – although there are proven and effective industry standard mitigation measures used to control erosion on slopes and banks, erosion at some sites is likely to occur.
- Confidence: high – based on data pertinent in the Project area and the professional experience of the assessment team.

Inadvertent Drilling Mud Release

Although unlikely, it is possible for a drilling mud release to occur during HDD crossings that could introduce sediment to surface water. The impact balance of this potential residual effect is considered negative since the release could decrease surface water quality.

The HDD method of trenchless pipeline installation is one of the lowest impact watercourse construction techniques (CAPP 2004). Successful implementation of the HDD method is, however, dependent upon many factors. Trans Mountain will endeavour to reduce risks of drilling mud release through accurate geotechnical evaluations, proper planning, suitable and well-maintained equipment, experienced personnel and adequate contingency planning.

In 2003, Trans Mountain replaced a segment of its existing Trans Mountain Pipeline system across the Fraser River to minimize exposure of the pipeline to seismically triggered lateral spreading. The 2.3 km crossing was conducted by horizontal directional drilling. Despite the engineering and geotechnical complexities of such a long HDD, the crossing was considered a success and no drilling mud was released into the watercourse. Although no HDD crossings were technically feasible for TMX Anchor Loop Project, other recent pipeline projects have conducted successful HDD crossings of major watercourses, for example, an HDD method was successfully implemented at the South Saskatchewan River (TERA 2011d) as well as at the Pouce Coupe and the Kiskatinaw rivers (TERA 2013c).

Trans Mountain plans to implement the HDD crossing technique at many of the larger and more sensitive watercourses, including the North Saskatchewan, McLeod, Pembina, North Thompson, Blue, Raft, Clearwater, Thompson, Nicola, Coldwater, Coquihalla (at RK 1043.2), Chilliwack/Vedder and lower Fraser rivers. To avoid or reduce effects of a drilling mud release on surface water quality, Trans Mountain will continually monitor for sediment release (*i.e.*, turbidity and TSS) throughout the crossing construction period. In the event of a release into a watercourse, Trans Mountain will immediately suspend drilling activities and implement measures outlined in the Drilling Mud Release Contingency Plan to reduce effects of drilling mud release into the watercourse. Any releases would be reported to DFO and AESRD or BC MOE and clean up and monitoring will be carried out until water quality is returned to existing (background) conditions.

The mud used for HDD crossings will be suitable for use in waterbodies. Appropriate drill paths will be established and drilling mud pressures and returns monitored to reduce the risk of inadvertent releases of drilling mud during an HDD. Although sediment input could occur, the proposed mitigation measures are expected to reduce the magnitude of a drilling mud release on the surface water quality indicator to low to medium levels. This residual effect is reversible in the immediate to short-term (Table 7.2.3-3, point 1[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – any drilling mud released during construction activities will be carried downstream until it disperses and/or naturally settles out.
- Duration: immediate to short-term – the event causing a decrease in surface water quality is the release of drilling mud, the period of which may be less than or equal to two days for small releases or could extend for longer, but less than 1 year.
- Frequency: accidental – the release of drilling mud into surface water occurs rarely over the assessment period.
- Reversibility: immediate to short-term – suspended sediments resulting from a drilling mud release would settle out of suspension within 24 hours after the release, however, any sediments that result in deposition on the substrate of a watercourse are expected to be flushed from the system during the first annual natural flushing event following construction.
- Magnitude: low to medium – depending upon the volume of the drilling mud release and the sensitivity of the receiving watercourse.
- Probability: low – it is unlikely that an accidental release of drilling mud would occur; however, in the event of an accidental release of instream drilling mud during an HDD crossing, the probability of a temporary reduction in surface water quality is high.
- Confidence: moderate – based on Trans Mountain's previous experience crossing the lower Fraser River in 2003, success of HDD crossings from similar projects and the professional experience of the assessment team.

Alteration or Contamination as a Result of Withdrawal and Release of Hydrostatic Test Water

Surface water quality could be compromised from increased suspended solids at the intake area during withdrawal of test water and, although unlikely, contamination during release of hydrostatic test water containing residual chemicals or other substances from inside the pipe. The impact balance of this potential residual effect is considered negative since the withdrawal or release of hydrostatic test water could decrease surface water quality.

The Environmental As-Built Report for the TMX Anchor Loop Project states that the East Spread (in Alberta) of the pipeline was hydrostatically tested in the spring of 2008, while the West Spread (in BC) was tested in the fall of 2008. Water was withdrawn from the Athabasca, Snaring, Miette, Moose and Fraser rivers. No additives were used during testing and water was returned to the source basin after testing. To reduce water hauling, water usage and the number of dewatering points, test water was shunted ahead from test section to test section. At all seven of the dewatering locations, water quality was tested prior to release and found to be within provincial and federal water quality parameters (TERA 2009a).

Hydrostatic test water for the proposed Edmonton to Hinton Segment is expected to be withdrawn from the North Saskatchewan, Pembina and McLeod rivers. Hydrostatic test water for the proposed pipeline segments in BC is expected to be withdrawn from the Fraser, Canoe, North Thompson, Thompson, Coldwater, Coquihalla and Sumas rivers. An estimated 81,000 m^3 of water will be needed to conduct hydrostatic testing for the Edmonton to Hinton Segment, while approximately 311,000 m^3 is estimated to be required for the remaining pipeline segments. Hydrostatic test water will be shunted from test section to test section, where feasible, allowing for less water to be used. All hydrostatic testing activities will be performed in accordance with the *NEB Onshore Pipeline Regulations (NEB OPR)*, provincial legislation, codes of practice and guidelines as well as the latest version of CSA Z662.

After hydrostatic testing the pipeline, the test water will be returned to its source basin. The inside of the pipe will be uncoated and is expected to have some rust particles. Otherwise, the pipe and tanks are not expected to contain petroleum products or other contaminants. The water ready for release will be aerated (*e.g.,* by spraying) to restore free oxygen displaced during pressuring, filtered as needed to remove rust particles (expected mainly at the beginning and end of each batch), and released. During initial release, the water will be visually inspected for evidence of foreign particles or contaminants exhibiting a surface sheen, and in the absence of such, the release will continue. Periodic visual inspections will then be made throughout the release period. The release water will be sampled near the beginning, during the middle and near the end of the release and analyzed according to parameters listed in the Water Withdrawal and Discharge Procedures Management Plan (Pipeline EPP [Volume 6B]). Water will typically be released onto a non-erodible surface (*e.g.,* rock aprons, plastic sheeting, plywood), and directed to flow through established vegetation before returning to a watercourse.

Similar measures implemented for water withdrawal and discharge for hydrostatic testing during testing activities associated with construction of the pipeline for the TMX Anchor Loop Project will be implemented for the construction of the proposed pipeline. With the implementation of the mitigation measures, the residual effect of hydrostatic water release and withdrawal is considered to be of low magnitude and reversible immediately or in the short-term since suspended sediments resulting from test water release will likely settle out of suspension within 24 hours after the release or, if the water chemistry is not suitable, water will be disposed of at a licensed facility (Table 7.2.3-3, point 1[d]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – any sedimentation or contaminants caused by withdrawal or discharge of hydrostatic test water could be carried downstream of the withdrawal and release locations.
- Duration: short-term – the event causing the alteration or contamination of the aquatic environment (*i.e.*, hydrostatic testing of the pipeline) is limited to a period of several weeks.
- Frequency: isolated – alteration or contamination of the aquatic environment caused by hydrostatic testing is confined to the construction phase.
- Reversibility: immediate to short-term – any suspended sediments resulting from test water release will likely settle out of suspension within 24 hours after release.
- Magnitude: low – based on the mitigation strategies including limiting withdrawal volumes and testing water prior to release and avoiding erosion during the release of test water.
- Probability: low – with implementation of mitigation strategies, it is unlikely that hydrostatic testing will cause an effect on the surface water quality indicator.
- Confidence: high – based on the professional experience of the assessment team and outcomes of the testing program for the TMX Anchor Loop Project, and since no release directly into a watercourse is planned.

Contamination of Surface Water Due to Small Spills

A spill during construction or site-specific maintenance activities could cause contamination of the surface water and would be considered to have a negative impact balance; however, with proper implementation of industry and government recommended mitigation measures, the effects can be limited. For example, during the construction of the TMX Anchor Loop Project, all fuel trucks, service trucks and pick-ups with box-mounted fuel tanks were required to carry spill prevention, containment and clean up materials. Furthermore, all hazardous material storage and oil changes, refuelling, and lubrication of industrial equipment were required to occur more than 100 m from a waterbody or watercourse except where secondary containment was provided. Spills or accidental release of potentially harmful materials (*i.e.*, oil or diesel fuel) were recorded. The Spill Contingency Plan was implemented on each spot spill and all spills were cleaned up as soon as they were discovered. During the TMX Anchor Loop Project, all spills were terrestrial, and no spills or leaks occurred in, or reached, a waterbody or watercourse (TERA 2009a).

Similar spill prevention mitigation is planned for the Project and spill prevention measures outlined in Table 7.2.3-2 and the Pipeline EPP (Volume 6B) will be followed. Fuel storage and handling practices will be monitored throughout construction of the Project to reduce spill risk. Should a leak be spotted or detected during construction of the pipeline, Trans Mountain will implement the Spill Contingency Plan (Volume 6B). Depending on the nature, volume and location (*e.g.,* sensitivity of receiving waterbody) of a spill, the magnitude of change to water quality could vary from low to high. This residual effect is reversible in the short to medium-term and is of low probability (Table 7.2.3-3, point 1[e]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – a spill during construction or site-specific maintenance activities may extend beyond the proposed pipeline corridor and evidence suggests that effect of most minor spills is localized (effects of a low probability large spill into a watercourse are considered in Volume 7).
- Duration: immediate – the event causing a potential reduction in surface water quality is a spill, the period of which is less than or equal to two days.
- Frequency: accidental – a spill into surface water occurs rarely over the assessment period.
- Reversibility: short to medium-term – the effects of a spill are not expected to last beyond 1 year, but may last longer depending on seasonal conditions and the extent and source of the spill.
- Magnitude: low to high – depending upon the volume, location and contaminant released.
- Probability: low – due to mitigation measures in place to reduce the potential for spills reaching water bodies and affecting surface water quality.
- Confidence: moderate – spill location and effects of accidental spills cannot be accurately predicted.

Combined Effects on Surface Water Quality

An evaluation of the combined effects considers those residual effects that are likely to occur. Therefore, residual effects 1(c) through 1(e) in Table 7.2.3-3 are not considered in the evaluation of combined effects on the surface water quality indicator since the probability of these effects occurring is low. Consequently, the combined effects evaluation considers the individual potential residual effects evaluated in Section 7.2.3.6 (points 1[a] and 1[b] of Table 7.2.3-3) that are likely to occur, and could act in combination on the surface water quality indicator.

The following potential residual effects are likely to act in combination to result in overall effects on the surface water quality indicator:

- reduction in surface water quality from suspended sediments during instream construction at trenched and temporary vehicle crossings; and
- reduction of surface water quality due to erosion from banks or approach slopes.

The adverse effects identified have the potential to act in combination on waterbodies and watercourses encountered along the proposed pipeline corridor. The reversibility of this residual effect is considered immediate to medium-term depending on the waterbody or watercourse encountered and the probability of these residual effects acting in combination at any specific location along the proposed pipeline corridor. However, the magnitude of the combined effects on the surface water quality indicator is considered to be low to medium since the combined effect is likely to be reduced by implementation of mitigation strategies for each of the residual effects (Table 7.2.3-3, point 1[f]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – combined effects on the surface water quality indicator may extend beyond the pipeline right-of-way to the predicted ZOI.
- Duration: short-term – the event causing the potential combined effects on the surface water quality indicator is construction of the pipeline.
- Frequency: isolated to occasional – the events causing the potential combined effects on the surface water quality indicator (*i.e.,* pipeline construction and maintenance activities) occur during construction and, for operations activities, intermittently and sporadically over the assessment period.
- Reversibility: immediate to medium-term – combined effects on the surface water quality indicator may be reversible immediately or may several years to return to existing conditions depending on the types of effects.
- Magnitude: low to medium – combined effects on the surface water quality indicator are anticipated to be largely mitigated during construction.
- Probability: high – the proposed pipeline corridor crosses a number of watercourses for which the above effects can act in combination to reduce surface water quality.
- Confidence: high – based on available research literature, data pertinent to previous crossings along the existing TMPL right-of-way and the professional experience of the assessment team.

<u>Water Quality and Quantity Indicator – Surface Water Quantity</u>

The following provides the evaluation of significance of potential residual effects on the surface water quantity indicator.

Alteration of Natural Drainage Patterns

With proper implementation of the industry-accepted standard mitigation practices that are proposed, disruption of surface flow patterns following construction or maintenance activities is expected to be minor along the proposed pipeline corridor. However, construction activities may contribute to some localized alteration of natural surface drainage patterns until trench settlement is complete. The impact balance of this potential residual effect is considered negative since it could alter or disrupt natural above ground hydrologic conditions.

In the event that construction or maintenance activities result in changes in surface water regimes, corrective action, in consultation with the appropriate regulatory authorities, will be implemented to resolve the issue. The post-construction environmental monitoring program will identify any locations with altered drainage patterns (*e.g.,* ponded water) and remedial work will be conducted, where warranted. Consequently, the residual effect is reversible in the short to medium-term. Some minor incidents (*e.g.*, ponding, minor flooding, erosion) are expected following construction and are considered to be within environmental standards, and therefore, of low to medium magnitude (Table 7.2.3-3, point 2[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – although alteration of natural drainage patterns is generally confined to the disturbed portion of the construction right-of-way, potential changes in hydrology may extend beyond the pipeline right-of-way.
- Duration: short-term – the events causing alteration of natural drainage are pipeline construction or maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year of the operations phase.
- Frequency: isolated to occasional – the events causing alteration of natural drainage (*i.e.*, pipeline construction and maintenance activities) occur during construction and, for operations activities, intermittently and sporadically over the assessment period.
- Reversibility: short to medium-term – it may take more than 1 year plus adequate precipitation levels in order for the trench crown to settle and natural drainage patterns to be restored.

- Magnitude: low to medium – the potential for flooding or erosion exists until the natural drainage patterns are restored.
- Probability: high – excessive trench settlement or a remnant crown are likely to occur as a result of pipeline construction or site-specific maintenance activities and, consequently, are likely to affect natural drainage patterns in localized areas.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Alteration of Streamflow

Open cut and isolated pipeline crossing methods have the potential to result in alterations of natural streamflow, a concern that was specifically raised at the Langley Community Workshop and during general public consultation. Specific public concern was raised about the potential for increased disturbance to the bed and banks of the Coquihalla River, which was crossed approximately 16 times by the existing TMPL right-of-way. Reducing the number of sensitive watercourse crossings is an important environmental consideration in the routing process. By reducing the number of crossings along the proposed pipeline corridor to five, the extent of potential effects to the bed and bank complex of the Coquihalla River are greatly reduced. Furthermore, since an HDD trenchless crossing method is planned for all Coquihalla River crossings, potential effects to bed and banks may be avoided entirely. However, in the event the HDD method is not feasible at any crossing location, an open cut crossing technique will be used.

During the first year of post-construction environmental monitoring for the TMX Anchor Loop Project in 2009, all watercourse crossings were observed to be properly restored following pipeline installation (TERA 2009b). However, in August 2010, during the second year of post-construction environmental monitoring, intermittent flow at a watercourse at KL 409.1 was again identified, after previously being identified immediately following construction and restoration of the restored channel (October 2008). To improve channel flow, channel enhancement was conducted in 2010 within certain sections of the right-of-way where the channel contour was observed as flat, without a defined channel thalweg. This activity, along with additional enhancement work carried out in late September 2010, appeared to improve flow (TERA 2011a). Channel enhancements were determined to be functioning as intended during post-construction environmental monitoring in 2011 and the alteration of surface flow pattern was resolved (TERA 2011a).

With proper implementation of the industry-accepted standard mitigation practices that are proposed, alteration of natural streamflow resulting from open cut and isolated pipeline crossings is expected to be minor along the proposed pipeline corridor. However, crossing activities may contribute to some localized alteration of watercourse bed and banks until complete and stable restoration is achieved following construction. The impact balance of this potential residual effect is considered negative since it could alter or disrupt hydrologic conditions of watercourses. However, with proper implementation of the mitigation measures proposed, alteration of natural streamflow following construction is likely to be minor at all watercourse crossings where open cut and isolated pipeline crossing methods are used.

In the event that construction or maintenance activities result in alterations to watercourse hydrology, corrective action, in consultation with the appropriate regulatory authorities, will be conducted to resolve the issue. The post-construction environmental monitoring program will identify locations of altered streamflow (*e.g.,* damaged bed and banks) and remedial work will be conducted. Consequently, the residual effect is reversible in the short to medium-term. Generally, the residual effect of altered bed and banks is considered to be within environmental standards for pipeline construction and, therefore, is of low to medium magnitude (Table 7.2.3-3, point 2[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – although alteration of natural streamflow is generally confined to the disturbed portion of watercourse bed and banks, potential changes in watercourse hydrology may extend beyond the pipeline right-of-way.

- Duration: immediate to short-term – the events causing alteration of natural streamflow are pipeline construction or maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year of the operations phase.

- Frequency: isolated to occasional – the events causing alteration of natural streamflow (*i.e.*, pipeline construction and maintenance activities) occur during construction and, for operations activities, intermittently and sporadically over the assessment period.

- Reversibility: short to medium-term – it may take more than 1 year to fully restore and stabilize watercourse channel and associated flow conditions.

- Magnitude: low to medium – the potential for changes to streamflow exists but experience with past projects demonstrates that proper design and remedial work will reduce effect magnitude.

- Probability: high – alteration of bed and banks from open cut and isolated watercourse crossings will result from pipeline construction or site-specific maintenance activities and, consequently, alteration of natural streamflow is likely occur.

- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on Surface Water Quantity

The combined effects evaluation considers the individual potential residual effects evaluated in Section 7.2.3.6 (points 2[a] and 2[b] of Table 7.2.3-3) that are likely to occur, and could act in combination on the surface water quantity indicator.

The following potential residual effects are likely to act in combination to result in overall effects on the surface water quantity indicator:

- localized alteration of natural surface drainage patterns until trench settlement is complete; and

- disruption and alteration of natural streamflow from instream activities.

The adverse effects identified have the potential to act in combination on waterbodies and watercourses encountered along the proposed pipeline corridor. The reversibility of this residual effect is considered short to medium-term depending on the waterbody or watercourse encountered. However, the magnitude of the combined effects on the surface water quantity indicator is considered to be low to medium with the implementation of mitigation strategies (Table 7.2.3-3, point 2[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – combined effects on the surface water quantity indicator may extend beyond the pipeline right-of-way.

- Duration: short-term – the events causing the combined effects on the surface water quantity indicator are pipeline construction or maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year of the operations phase.

- Frequency: isolated to occasional – the events causing the combined effects on the surface water quantity indicator (*i.e.*, pipeline construction and maintenance activities) occur during construction and, for operations activities, intermittently and sporadically over the assessment period.

- Reversibility: short to medium-term – it may take more than 1 year to fully restore and stabilize watercourse channel and associated flow conditions.

- Magnitude: low to medium – combined effects on the surface water quantity indicator are anticipated to be largely mitigated during construction.

- Probability: high – the proposed pipeline corridor crosses a number of watercourses and drainages for which the above effects can act in combination to reduce surface water quantity.

- Confidence: high – based on data pertinent to previous crossings along the existing TMPL right-of-way and the professional experience of the assessment team.

Water Quality and Quantity Indicator – Groundwater Quality

The following provides the evaluation of significance of potential residual effects on the groundwater quality indicator.

Elevated Turbidity in Groundwater

Increased turbidity in groundwater may be the result of the effects from accidental drilling mud release, sedimentation or sediment release during blasting. In the case of an accidental drilling mud release, the turbidity originates with the drilling mud. In the other two cases, the turbidity results from a release of sediment particles in the formation. The turbidity in all three cases will decrease as the groundwater flows through the formation. Interconnected pores through which the groundwater flows are generally smaller than silt size particles causing the silt particles to be retained in the formation close to their source (*i.e.*, the location of the potential drilling mud release). This residual effect is considered to have a negative impact balance since elevated turbidity can affect groundwater quality. The residual effect of an elevated turbidity on groundwater quality is considered to be reversible in the short-term based on previous experience; particles either settle out or cannot pass through the pore space of the sediment (Table 7.2.3-3, point 3[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – particles in the groundwater naturally settle out within the LSA.
- Duration: short-term – the event causing the potential increase in turbidity of groundwater is construction activities.
- Frequency: accidental – the event causing the potential increase in turbidity occurs rarely over the assessment period.
- Reversibility: short-term – turbidity of groundwater is expected to decrease in the vicinity of the accidental drilling mud release or blasting.
- Magnitude: medium – depending upon the volume of accidental drilling mud released or sediment / silt introduced during blasting and the permeability of the formation.
- Probability: low – it is unlikely that an accidental release of drilling mud would occur or that blasting will release sediment or silt.
- Confidence: moderate – based on previous experience of the assessment team.

Groundwater from Different Aquifers may be Mixed

Drilling a borehole through multiple aquifers at different depths can result in cross-formational flow between two or more water bearing units resulting in mixing of those waters. This would be the case if drilling were to proceed through unconsolidated water-bearing surficial materials into deeper unconsolidated or bedrock aquifers. The proposed pipeline trench depth will typically be 2.1 m and, consequently, no residual effects resulting in aquifer mixing are anticipated during trenching activities and the potential effect is limited to drilling activities. In addition to horizontal directional drilling, drilling may also occur as part of the investigation prior to trenchless crossing activities.

In general, this effect would apply to shallow bedrock aquifers underlying unconsolidated water-bearing surficial materials. Drilling practice in this case would be to isolate the surficial materials before drilling proceeded to deeper depths. Proper abandonment of boreholes is necessary to prevent this effect from occurring. The impact balance of this residual effect is considered negative since this could adversely affect groundwater quality in an aquifer.

This residual effect on the natural groundwater and surface water systems in terms of water quality is considered to be reversible in the medium-term. Drilling activities that advance through more than one aquifer within the Water Quality and Quantity LSA are expected to be limited over the construction phase of the Project (Table 7.2.3-3, point 3[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – depending upon the site-specific conditions, potential affects could extend beyond the Footprint and into the LSA.
- Duration: short-term – the event causing the potential mixing of groundwater from different aquifers is construction of the pipeline.
- Frequency: accidental – this effect is expected to occur rarely over the assessment period and only during the construction phase.
- Reversibility: medium-term – with the implementation of mitigation measures in Table 7.2.3-2 and the Pipeline EPP (Volume 6B), the residual effect is likely to be reversible over a period of less than 10 years.
- Magnitude: low to high – depending on the difference in water quality between the two aquifers.
- Probability: low – this effect is unlikely to occur if the local groundwater conditions are understood and proper practices are observed during drilling and trenching.
- Confidence: moderate – based on professional experience of the assessment team.

Contamination of an Aquifer as a Result of a Spill During Construction

Contamination of an aquifer may result if the spilled material migrates through the developed soil near the surface through the surficial materials into the first water-bearing unit. The rate of migration is dependent upon the permeability of the materials, presence or absence of fractures, the properties of the spilled contaminant (density, viscosity) and the vertical hydraulic gradients. A spill during the construction phase of the Project is likely to be noted quickly and be of small volume, and evidence suggests that the effects of most minor spills are localized.

The impact balance of this residual effect is considered negative since this could potentially affect water quality in the aquifer. This residual effect is unlikely to extend beyond the Water Quality and Quantity LSA; it is considered to represent a short to medium-term influence on the natural groundwater and surface water systems depending upon the volume of the spill, and the properties of the aquifer and overlying material. Spills where the spilled material contaminates an aquifer within the Water Quality and Quantity LSA may occur accidentally over the construction phase of the Project (Table 7.2.3-3, point 3[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – a spill during construction activities may extend beyond the proposed pipeline corridor but based on professional experience the effects of most minor spills are localized.
- Duration: immediate – the event causing potential contamination of the aquifer is a spill, the period of which is less than one day.
- Frequency: accidental – a spill into groundwater during construction is rare.
- Reversibility: short to medium-term – the effects of a spill are not expected to last beyond 1 year, but may last longer depending upon the extent and source of the spill.
- Magnitude: low to high – depending upon the volume, location and contaminant released.
- Probability: low – due to mitigation measures in place to reduce the potential for spills migrating into the subsurface and affecting groundwater quality.
- Confidence: moderate – spill location and effects of accidental spills cannot be accurately predicted.

Water Quality and Quantity Indicator – Groundwater Quantity

The following provides the evaluation of significance of potential residual effects on the groundwater quantity indicator.

Natural Groundwater Pathways May Be Bisected and Create a Sink (Drain) for Shallow Groundwater

Excavation of the trench in areas of shallow groundwater or springs, during pipeline construction, can alter groundwater and surface water flow patterns. This may result in the trench becoming a sink. That is, both groundwater and surface water intersecting the trench will flow into the trench resulting in changed flow patterns.

The backfill of the trench around the pipeline will consist of native backfill as much as practical in order to maintain the soil/formation permeability similar to the pre-construction permeability. For example, if the trench was backfilled with a higher permeability material, the filled trench could become a preferred pathway for groundwater flow and, consequently, permanently change the natural flow pattern. Where there is concern for increased permeability, a trench breaker would be installed.

Upon backfilling the trench with native backfill, groundwater flow patterns will typically revert to their pre-construction state. Where springs are encountered, advice will be sought for the Hydrogeological or Geotechnical Resource Specialist so that cross drainage within the trench can be maintained. The impact balance of this residual effect is considered negative since groundwater flow down-gradient could temporarily decrease because flow is directed along the pipeline (Table 7.2.3-3, point 4[a]). Where there is concern for increased permeability, a trench breaker would be installed. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – depending upon the site-specific conditions, dewatering activities and groundwater discharge could extend beyond the Footprint and into the LSA.
- Duration: short-term – the events causing the potential alteration of groundwater flow are construction of the pipeline and maintenance activities, the latter of which are limited to any 1 year during operations.
- Frequency: periodic – the events causing alteration of natural groundwater flow (*i.e.,* pipeline construction and maintenance activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short-term – residual effects are expected to reverse within 1 year.
- Magnitude: low – the potential for changes to groundwater flow exists but experience with past projects demonstrates that proper design and remedial work will reduce the effects.
- Probability: low – although the proposed pipeline corridor crosses areas of shallow groundwater, areas with highly permeable materials near rivers and at crossings with fluvial or colluviums substrates and known springs, with the implementation of the mitigation measures outlined in Table 7.2.3-2, alteration of groundwater flow as a result of pipeline construction is unlikely.
- Confidence: moderate – based on previous experience of the assessment team and shallow groundwater mapping has been completed using available provincial mapping and existing well log reports.

Flooding on the Up-Gradient Side of the Pipeline May Result in Creation of Wet Zones on Ground Surface

A reduction in the permeability of materials along the groundwater flow path may result in a rise in the groundwater table to the extent that ground to surface flooding occurs. This may occur if the trench spoil is not backfilled in the correct order or soils are not properly salvaged resulting in a change in permeability of the upper trench materials and blocking of near surface groundwater flows. The impact balance of this residual effect is considered negative since this could potentially affect recharge to shallow aquifers or local streams or wetlands and create permanently wet areas. This residual effect is considered to have a short-term influence on the natural groundwater and surface water systems as long as mitigation measures are applied (Table 7.2.3-3, point 4[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – depending upon the site-specific conditions, dewatering activities and groundwater discharge away from the Footprint could affect an area within the LSA.
- Duration: short-term – the events causing the potential alteration of groundwater flow are construction of the pipeline and maintenance activities, the latter of which are limited to any 1 year during operations.
- Frequency: periodic – the events causing alteration of natural groundwater flow (*i.e.,* pipeline construction and maintenance activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short-term – the effects of pipeline trench construction are not expected to last beyond 1 year once the trench has been backfilled as long as mitigation measures are applied.
- Magnitude: low – the potential for changes to groundwater flow exists but professional experience demonstrates that proper design and remedial work will reduce the effect.
- Probability: low – the proper construction of the pipeline trench will reduce the occurrence of this effect.
- Confidence: moderate – based on previous experience and on data pertinent to the Project area.

Reduction of Base Flow to Local Streams

Dewatering of the pipeline trench during construction may result in lowering of the local water table which in the case of local streams may reduce the groundwater inflow (base flow) to streams. As indicated in Table 7.2.3-3 (point 4[d]), the extracted groundwater may be released to the ground or directly into a nearby stream in which case there would be minimal disruption of flow in the stream. The impact balance of this residual effect is considered negative due to the potential decrease of groundwater flow into local streams. This residual effect likely will not extend beyond the Water Quality and Quantity LSA to the watershed level, and, it is considered to represent a short-term influence on the natural groundwater and surface water systems (Table 7.2.3-3, point 4[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – depending upon the site-specific conditions, dewatering activities and groundwater discharge away from the Footprint could affect an area within the LSA.
- Duration: short-term – the events causing the reduction in baseflow are the result of discharge during dewatering and occur while the trench is being constructed (either for pipeline installation or for pipeline daylighting during integrity digs).
- Frequency: periodic – the events causing alteration of natural groundwater flow (*i.e.,* pipeline construction and maintenance activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short-term – the effects of pipeline trench construction are not expected to last beyond 1 year once the trench has been backfilled.
- Magnitude: low – the potential for changes to groundwater flow exists but professional experience demonstrates that proper design and remedial work will reduce effect magnitude.
- Probability: low – the proper construction of the pipeline trench will reduce the occurrence of this effect.

- Confidence: moderate – based on previous experience and on data pertinent to the Project area.

Change in Natural Groundwater Levels and Stream Recharge Due to the Discharge of Groundwater to Surface Water Systems if Not Practical to Discharge Trench Water to Ground

Shallow groundwater will be present in the subsurface in many areas along the proposed pipeline corridor. During pipeline construction, it is common practice to dewater the trench to allow the pipe to be laid down in a dry environment. Extracted groundwater from the dewatering operations will be disposed to ground where possible, but in areas where this is not practical, the water may be discharged away from the area, directly into a water body (post-treatment), or stormwater discharge system causing local groundwater levels and flow patterns to be temporarily disrupted. The impact balance of this residual effect is considered negative since this could potentially affect recharge to local streams or shallow aquifers. This residual effect is confined to the Water Quality and Quantity LSA and is considered to represent a short-term influence on the natural groundwater and surface water systems. Dewatering activities where the extracted groundwater cannot be returned to ground are unlikely to occur given the proposed mitigation measures in Table 7.2.3-2 and in the Pipeline EPP (Volume 6B). The residual effects in areas of discharge of collected groundwater are expected to reverse within 1 year when seasonal precipitation replenishes the aquifer (Table 7.2.3-3, point 4[d]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – depending upon the site-specific conditions, dewatering activities and groundwater discharge away from the Footprint could extend to the LSA.
- Duration: short-term – the event causing the discharge of groundwater from the trench is the construction of the pipeline.
- Frequency: isolated – dewatering activities are expected to occur at specific locations/times over the construction phase of the Project.
- Reversibility: short-term – residual effects are expected to reverse within 1 year once seasonal precipitation recharges the aquifer.
- Magnitude: low – it is not expected that dewatering activities will noticeably affect groundwater flow patterns given the implementation of mitigation measures.
- Probability: low – it is unlikely that groundwater flow patterns will be affected by dewatering activities given the implementation of proposed mitigation measures.
- Confidence: moderate – shallow groundwater mapping has been completed using available provincial mapping and existing well log reports.

Flooding from Artesian Flow May Occur During Trenchless Crossing Installation

There is a potential for a trenchless crossing or open cut to compromise the integrity of a confining unit that isolates an underlying productive aquifer (especially in valley bottom). A breach of the confining unit during pipeline construction activities may result in uncontrollable artesian flow at the entry or exit point of the trenchless crossing or along the alignment in the open cut. This condition may lead to the development of saturated surface conditions and permanent wet conditions at the discharge areas. In addition, loss of circulation that could occur during trenchless crossing may result in drilling fluids entering the creek bed or discharging to surface along the valley slope.

If areas of artesian conditions are encountered, the annulus of the borehole in the trenchless crossing (space between the pipe and the borehole wall) must be sealed (*e.g.,* with bentonite or grout). If this is not possible, construction of the trenchless crossing should not continue and the contingency trenched crossing should be implemented. The impact balance of this residual effect is considered negative since this could potentially result in adverse flooding conditions. This residual effect is not expected to extend beyond the Water Quality and Quantity LSA to the watershed level.

A complete understanding of the hydrogeological and geotechnical conditions, identification of risks before commencing the trenchless crossing is necessary. In addition, completion of an alignment site reconnaissance, possibly supported by a drilling and testing program designed to confirm hydrogeological and geotechnical conditions and designing the trenchless crossing and pipeline installation to prevent artesian flow to surface are also necessary to reduce the potential effects.

With these mitigation measures, the residual effect of flooding from artesian flow on the natural groundwater and surface water systems is considered to be reversible in the short-term and of low to medium magnitude (Table 7.2.3-3, point 4[e]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Groundwater Water Quality and Quantity LSA – depending upon the site-specific conditions, trenchless crossing activities could affect an area within the LSA.
- Duration: immediate to short-term – the event causing this effect is drilling during trenchless crossing activities which may extend more than two days depending on the size of the watercourse.
- Frequency: isolated – the event causing this effect occurs only during the pipeline construction phase.
- Reversibility: short-term – flooding associated with artesian flow will be reversed in 1 year.
- Magnitude: low to medium – the potential for changes to groundwater flow exists but experience with past projects demonstrates that proper design will mitigate the magnitude of the effect.
- Probability: low – experience with past projects demonstrates that proper design will mitigate the effect.
- Confidence: moderate – based on previous experience and on data pertinent to the Project area.

Reduction of Water Quantity if Blasting Damages the Well or the Surrounding Formation

A reduction in water quantity may occur if blasting closes or clogs fractures supplying an existing water well. Based on previous experience, this condition is unlikely to occur, although blasting or the movement of heavy equipment in the vicinity of a well may damage a well casing or cause collapse of a borehole.

The impact balance of this residual effect is considered negative since this could potentially affect the water supply to the wellbore. This residual effect is unlikely to extend beyond the Water Quality and Quantity LSA to the watershed level. It is considered to represent a short-term influence on the natural groundwater and surface water systems. In the case of a water supply well, should a well be damaged as a result of construction activities, Trans Mountain will re-establish or replace the potable water supply (see Table 7.2.3-2). Blasting activities where the integrity of the water well is affected within the Water Quality and Quantity LSA would accidentally occur over the construction phase of the Project (Table 7.2.3-3, point 4[f]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – depending upon the site-specific conditions, it is unlikely that blasting activities would affect an area extending more than 300 m from the corridor.
- Duration: immediate – the event causing this effect is blasting which occurs over a period of less than or equal to two days.
- Frequency: accidental – a reduction in well water quantity as a result of blasting occurs rarely over the assessment period.
- Reversibility: short-term – once either the well has been damaged or the formation fractures have been closed or clogged, it is unlikely that they will re-open without outside influence. However, repair or replacement of the water supply well will ensure this effect is reversible.
- Magnitude: low to medium – the potential for well damage or changes to fracture systems as a result of blasting exists but experience with past projects demonstrates that proper design will reduce the magnitude of the effect.
- Probability: low – past experience indicates that this effect, although possible, occurs relatively rarely.

- Confidence: moderate – based on previous experience.

Enhancement of Water Quantity if Blasting Opens or Unclogs Fractures Supplying Existing Water Well

An increase in water quantity may occur if blasting opens or unclogs fractures supplying an existing water well. The blasting, if in proximity to a water well, may further prop open fractures increasing the amount of groundwater flow through the fractures. Blasting, if it occurs sufficiently close to the water well, may also loosen formation particles and scale (from well infrastructure) in the wellbore resulting in temporary increased turbidity of the water. In addition, damage to the well screen and casing may occur as a result of the blasting.

The impact balance of this residual effect may be considered negative since this could potentially increase the water supply or yield of the well at the expense of well integrity and well water quality. This residual effect is unlikely to extend beyond the Water Quality and Quantity LSA. It is considered to represent a short-term influence on the natural groundwater and surface water systems. Blasting activities resulting in enhanced water quantity within the Water Quality and Quantity LSA may occur accidentally during the construction phase of the Project. Blasting as well as the movement of heavy equipment should be conducted 100 m (non-explosives) to 200 m (explosives) away from existing water wells (Table 7.2.3-3, point 4[g]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA - depending upon the site-specific conditions, it is unlikely that blasting activities would affect an area extending more than 300 m from the proposed pipeline corridor.
- Duration: immediate – the event causing this effect is blasting which lasts less than one day.
- Frequency: accidental – an increase in water quantity as a result of blasting occurs rarely over the assessment period.
- Reversibility: short-term – once fractures have been opened or unclogged they may remain open; however, the groundwater flow in a large scale will be unaffected and the well water supply may return to the pre-blasting balance.
- Magnitude: negligible – the potential for changes to fracture systems as a result of blasting exists but experience with past projects demonstrates that proper design will reduce effect magnitude as mentioned above.
- Probability: low – this is unlikely to occur if proper precautions are taken during blasting operations.
- Confidence: moderate – based on previous experience.

7.2.3.7 Summary

As identified in Table 7.2.3-3, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on water quality and quantity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline construction and operations on water quality and quantity will be not significant.

7.2.4 Air Emissions

This subsection describes the potential Project effects on air emissions. The Air Quality and Greenhouse Gas Technical Report of Volume 5C provides further information pertaining to existing air quality conditions along the proposed pipeline corridor.

7.2.4.1 Assessment Indicators and Measurement Endpoints

Selection of indicators for air emissions considered: the filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues; feedback from Aboriginal engagement, landowners, regulatory authorities, stakeholders and the general public; available research literature; and professional judgment of the assessment team. The assessment indicator selected for use in the assessment of construction and operation of the pipeline on air quality is listed in Table 7.2.4-1. The proposed air emissions indicator for pipeline construction and operation (*i.e.*, primary emissions of criteria air contaminants [CACs] and volatile organic compounds [VOCs]) was discussed during the Edmonton, Kamloops and Surrey ESA Workshops. There was general consensus among workshop participants that the proposed air emissions indicator was appropriate for evaluating effects of pipeline construction and operations on air emissions. Consideration was also given to Canadian National Ambient Air Quality Objectives, Canadian Ambient Air Quality Standards, Provincial Ambient Air Quality Objectives of Alberta and BC and World Health Organization Guidelines. Input on indicator selection was sought from Environment Canada, BC MOE, FVRD, Metro Vancouver and PMV (Section 3.0); no additional indicators were suggested for consideration in assessment of pipeline construction and operations.

Both quantitative and qualitative measurement endpoints are applied to assess potential effects of pipeline construction and operation on the air emissions indicator. No direct air emissions are expected from operation of the pipeline itself except for pipeline inspection and maintenance activities.

The indicators of secondary particulate matter and ozone, and hydrogen sulphide and mercaptans emissions, are included in Table 7.2.4-1 and apply to the proposed terminal expansions. Further information on the selection of these indicators and measurement endpoints is provided in Sections 7.5.4 and 7.6.4.

TABLE 7.2.4-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR AIR EMISSIONS

Air Emissions Indicator	Measurement Endpoints	Rationale for Indicator Selection
Primary emissions of CACs (PM, CO, NO_2 and SO_2) and speciated VOCs (*e.g.*, BTEX)	• Emissions from Project construction and comparison to existing emissions • Emissions from Project operation and comparison to existing emissions	The selection of the indicator and measurement endpoints considered NEB *Filing Manual* requirements for the air emissions element in Table A-2, addressed concerns raised through stakeholder engagement and were informed by regulatory authorities (*i.e.*, Environment Canada, BC MOE, Metro Vancouver, FVRD and PMV).
Formation of secondary ozone	• Predicted levels of ambient ground-level ozone concentrations and comparison to ambient air quality criteria	
Hydrogen sulphide (H_2S) and mercaptans emissions which have the potential to cause nuisance odours	• Predicted levels of ambient ground-level concentrations and comparison to odour detection thresholds	

7.2.4.2 Spatial Boundaries

The following spatial boundaries are used in the air emissions effects assessment:

- a Footprint Study Area (as defined in Section 7.1.3); and
- an Air Quality RSA.

The Air Quality RSA includes the area where the direct and indirect influences of other activities could overlap with the Project-specific effects from the pipeline and cause cumulative effects on the air quality indicator. The Air Quality RSA width varies by indicator. For example, it consists of a 5 km wide band generally extending from the proposed pipeline corridor (*i.e.*, the Footprint plus 2.5 km on both sides of the proposed pipeline corridor). For the five terminal facilities, the Air Quality RSA is 24 km by 24 km centred on the facility. Being only 3 km apart, Burnaby Terminal and the Westridge Marine Terminal were combined with a common Air Quality RSA. The spatial boundaries of the Air Quality RSA are shown on Figures 5.4-1 to 5.4-4.

The Air Quality RSA was discussed during the Edmonton, Kamloops and Surrey ESA Workshops. There was general agreement that the spatial boundaries for air emissions were appropriate to assess the effects of pipeline and associated facilities construction and operations, and no alternative boundaries were suggested for consideration by the assessment team.

Photochemical modelling of secondary formation of $PM_{2.5}$ and ozone and visibility requires the inclusion of a broader set of emissions from residential, transportation, and industrial sources, changes in land use and terrain, and varying meteorological conditions. In addition, adequate time is needed for atmospheric chemical reactions and predictions at locations well outside the smaller Air Quality RSAs, which are sufficient for dispersion modelling. Over the long modelling period, chemical and meteorological influences are carried into the Project area, requiring large outer modelling domains as well as a larger inner domain that includes the Lower Fraser Valley (LFV; shown in Figure 4.2-4 of the Air Quality and Greenhouse Gas Technical Report of Volume 5C). In the context of photochemical modelling, this inner domain is essentially the photochemical RSA. However, to avoid confusion with the Air Quality RSA and to emphasize that it includes the entire Lower Fraser Valley, the term ‘LFV photochemical model domain’ is used. It comprises a 412 km x 688 km area at 4 km resolution centred on the LFV and covering southern BC and northern Washington State, including Vancouver Island, Juan De Fuca Strait, and the Salish Sea. This inner domain is embedded in a larger 1,068 km x 840 km intermediate domain at 12 km resolution covering the southern half of BC plus Washington and Oregon states in the US. The intermediate domain is embedded in a 3,420 km x 3,348 km parent domain at 36 km resolution covering much of Western North America including BC and Alberta and the US Pacific States. Emissions scenarios for TMEP were implemented over the inner 4 km domain, with the boundary condition determined from Baseline 36 km and 12 km model results. The spatial boundary of the LFV photochemical modelling domain takes into account the results of consultation conducted to date with the FVRD as well as BC MOE and Environment Canada. This regional model domain is also consistent with an earlier study conducted by the University of British Columbia (Steyn *et al.* 2011).

7.2.4.3 Project Associated Air Emissions

During the construction phase, land clearing for right-of-way and facilities and other construction activities will result in fugitive dust emissions, while the operation of vehicles and equipment will result in emissions of CACs and VOCs. During operations, service and maintenance vehicles and aerial patrols will emit CACs and VOCs. Fugitive VOC emissions are expected at connectors, flanges, and valves. In a few cases, CACs and VOCs will be emitted where local fossil fuel burning is required (*e.g.,* for propane heaters).

Emissions from Project activities during the construction phase were estimated using available information. All Project construction emissions will be intermittent and limited in duration. Furthermore, the spatial and temporal characteristics of Project-related construction activities are difficult to define. For these reasons, dispersion modelling of the estimated emissions was not deemed valuable for the assessment of potential air quality effects from Project construction. For Project operations, dispersion modelling was performed where expected emissions warranted an estimation of associated ambient concentrations. This will be discussed in the following subsections under pump stations, tank installation and operations, and Westridge Marine Terminal.

Table 7.2.4-2 summarizes the estimated total construction and annual operation emissions by pollutant for each component or facility type associated with the Project, not including existing emissions. For ease of comparison, construction and operations emissions for all components and facility types are shown in the table and discussed in the following subsections. Subsequent subsections on pump stations, tanks, and the Westridge Marine Terminal refer back to this subsection.

TABLE 7.2.4-2

EMISSIONS OF AIR CONTAMINANTS RELATED TO CONSTRUCTION AND OPERATION (EXPRESSED AS NET CHANGE FROM EXISTING CONDITIONS) (in kg)

Component or Facility	Oxides of Nitrogen (NO_x)	Carbon Monoxide (CO)	Sulphur Dioxide (SO_2)	Inhalable Particulate Matter ($PM_{2.5}$)	Respirable Particulate Matter (PM_{10})	Ammonia (NH^3)	Total Volatile Organic Compounds (TVOCs)	Hydrogen Sulphide (H_2S)	Total Mercaptans
Construction (Total)									
Pipeline	402,600	114,800	665.6	15,630	16,500	0	27,000	0	0
Pump Stations	303,800	68,730	417.4	12,030	12,570	0	17,930	0	0
Tanks	175,000	79,980	419.4	6,681	7,036	0	12,240	0	0
Westridge Marine Terminal	99,890	27,690	1,266	3,070	3,255	0	7,427	0	0
Net Change in Operations (Annual)[1]									
Pipeline	Negligible	Negligible	Negligible	Negligible	Negligible	0	Negligible	Negligible	Negligible
Pump Stations	Negligible	Negligible	Negligible	Negligible	Negligible	0	21,450	Negligible	Negligible
Tanks	<0.05	<0.05	<0.05	<0.05	<0.05	0	14,780	0.1	1.6
Westridge Marine Terminal[2]	77,790	-98,390	3,821	-153,000	-155,000	9	802,400	1.0	34.2

Notes: 1 Operations expressed as net change from existing emissions, and negative values may reflect use of new emission controls.

2 Ammonia emission sources include marine vessels in transit.

New Pipeline

Emissions from construction of the pipeline segments are higher than for other components and facilities associated with the Project, and constitute roughly 40% of total Project construction emissions. This is expected given the substantially larger spatial Footprint of new pipeline segments compared to other Project components and facilities. In addition, estimated air emissions resulting from pipeline construction are reduced through the implementation of the mitigation measures outlined in Table 7.2.4-3.

CAC and VOC emissions during pipeline operations are negligible. During operation of the pipeline, emissions will be limited to aerial patrols. No net increase in the frequency or duration of aerial patrols is expected, and there is no anticipated increase in emissions due to pipeline operations. Therefore, it was not necessary to estimate ambient concentrations of CACs or VOCs associated with pipeline operations. Emissions associated with maintenance activities could not be broken down into specific facilities or components; therefore, no appropriate scaling of these emissions to account for the pipeline expansion could be established. It is expected, however, that the annual operations emissions are small compared to total construction emissions.

Pump Stations

During the construction of pump stations, site preparation, operation of vehicles and equipment, and other construction activities will result in air emissions. It is assumed that no burning of slash will be required for the construction of pump stations. Detailed design information was not available, yet, to estimate slash burning and clear cutting for pump stations, for example for access roads or additional power lines. However, estimates of clear cutting for pipeline right-of-way are conservative; the overestimates are substantially larger than clear cutting required for pump stations. At this stage it was also assumed that all 'new' or relocated pump stations and pressure control stations require construction of a complete new pump station facility. However, in most cases, pump stations might only require the addition of pumps to an existing building, and there is substantially less activities required for the construction of pressure control stations. With this conservative assumption, pump stations are expected to be the second largest source of CAC and VOC emissions during construction, roughly 30% of total construction emissions. This result is reasonable by comparison with smaller sources (tank installations and Westridge Marine Terminal expansion), because construction activities associated with a new pump station facility are substantial, and it is assumed that there are more pump stations being constructed than there is work at the existing terminals.

During operations, increases of fugitive VOC emissions are expected from flanges, control valves, compressor pump seals, and open ended lines. Also, CACs and VOCs will be emitted where local fossil fuel burning is required (*e.g.,* for propane heaters), but these are expected to be negligible. Service and maintenance vehicles will emit CACs and VOCs intermittently. These emissions are considered to be negligible compared to other vehicle emissions in the area that are not associated with the Project. In the absence of detailed information, it is assumed that aerial patrols will primarily serve pipeline segments and that the Project will not cause an increase in aerial patrols.

Tank Installation and Operation

Construction equipment used for tank installation will emit CACs and VOCs. These emissions for all tanks range from 7% to 24% of total Project construction emissions, dependent on the emission type.

During tank operations, Project-related CAC emissions are less than one gram per year, and emissions of H_2S and mercaptans are small. Most emissions are fugitive VOC, including benzene, toluene, ethylbenzene, and xylene, known collectively as BTEX. These are associated with fluctuating fluid levels of product in the storage tanks (working losses) and changes in barometric pressure and ambient temperature (standing losses). The pump rates for filling and withdrawal of product and the physical design of the roof seals and tanks were used as input into the US Environmental Protection Agency (EPA) emission model called TANKS. Fugitive emission rates for a selected set of pollutants were calculated for each product stored in the tanks. The CALPUFF dispersion model was used to evaluate the combined effect of the fugitive emissions from each tank terminal at off-site receptors. At the Sumas, Burnaby, and Westridge Marine Terminals, and based on very preliminary design engineering, Trans Mountain is proposing to include emission control systems (Tank Vapour Activation Units or TVAUs) to reduce emissions of reduced sulphur and VOCs using an H_2S scavenging technology called SULFATREAT and activated carbon filters for the new tanks. The TVAUs were accounted for in the emission calculations for these tanks in the dispersion model.

Dispersion modelling was conducted in accordance with the air quality modelling guidelines in Alberta (AESRD 2013a) and BC (BC MOE 2008). Interpretation of the predicted results (plus ambient background concentrations) was also conducted using the modelling guidelines. The predicted results were assessed in terms of applicable ambient air quality objectives from several regulatory authorities specific to each terminal location including Metro Vancouver, BC MOE, AESRD and Environment Canada. These objectives are based on environmental or human health effects and include several averaging periods such as 24-hour and annual.

The addition of tanks to the Edmonton, Sumas, and Burnaby terminals will increase fugitive emissions. In the absence of more detailed information, it was assumed that the additional tanks will not increase fleet operation and the use of space heating. It can also be assumed that these emissions would be small compared to ambient concentrations.

In addition to emissions of primary pollutants from the Project, secondary pollutants will be formed from reactions between primary pollutants in the atmosphere. In the presence of sunlight, precursors such as NO_X and VOCs undergo a complex sequence of reactions to form ozone. Secondary PM can be formed from reactions between NO_X, SO_X, and NH_3. Primary and secondary PM can absorb and scatter sunlight, causing haze and obscuring visibility.

Advanced photochemical modelling using Community Multiscale Air Quality (CMAQ) was performed to estimate the difference in the formation of secondary PM and ozone between baseline emissions and total emissions after the addition of Project-related emissions of: CAC and VOC in the Lower Fraser Valley (LFV) from increased Project-related transportation by ship; fugitives at tanks in the Burnaby and Sumas terminals; and CAC from equipment and fugitives associated with loading products on ships and tank storage at the Westridge Marine Terminal. Note that the chemical interaction between primary pollutants and the formation of secondary PM and ozone is non-linear, hence not additive. It is therefore not possible to determine the contribution of individual sources to overall PM and ozone formation and visibility in the LFV. Results for land-based receptors are reported in terms of the net effect of all changes associated with the Project.

Westridge Marine Terminal Expansion and Operation

Construction equipment used for the Westridge Marine Terminal Expansion will emit CACs including VOCs. These are the smallest emissions among the components and facilities listed in Table 7.2.4-2 above, roughly 10% of total construction emissions with the exception of SO_2. Approximately half of all construction related SO_2 emissions are estimated to occur during Westridge Marine Terminal expansion. The main source of this SO_2 is sulphur contained in the marine diesel oil that is combusted by the vessels used during berth construction.

Emissions from operations at the Westridge Marine Terminal include the same sources as tank operation, which was described above. In addition, CAC emissions from equipment operations are expected, and fugitive emissions from ships at berth are considered terrestrial operation emissions at the Westridge Marine Terminal. During ship loading, roughly 90% of fugitive emissions are flared with a VCU, which is currently a substantial source of CAC and VOC emissions at the Westridge Marine Terminal. However, emissions of all CACs with the exception of NH_3 will be reduced after the installation of the TVAUs described above. Emissions of total VOCs, H_2S, and mercaptans are expected to increase. Exhaust emissions from Project-related increases of ships at berth are expected to cause net increases in NO_x and SO_2 emissions.

The formation of secondary PM and ozone and reductions in visibility are affected by CAC and fugitive VOC emissions during operations at the Westridge Marine Terminal. Refer to the discussion on tank installation and operations above for details.

7.2.4.4 Potential Effects and Mitigation Measures

Effects Considerations

Two concerns related to air emissions were raised during the Edmonton, Kamloops, and Surrey ESA Workshops: radioactive dust from pipeline construction activities; and black carbon from the burning of timber associated with land clearing. Radioactive dust and black carbon were not included as assessment indicators but are discussed indirectly. Under the authority of the *Environmental Management Act*, the BC MOE has the mandate to regulate smoke emissions that would include radioactive dust and black carbon from open burning activities through the application of the *Open Burning Smoke Control Regulation*. Trans Mountain will burn slash when conditions exist that allow for adequate dispersion of smoke and will observe the appropriate setback distances and other best management practices. In the Lower Fraser Valley where air quality is an issue, Trans Mountain will avoid burning slash. Instead, mulching will be performed in place or slash will be shipped/hauled to an approved disposal location.

Identified Potential Effects

Potential effects of the construction and operations of the proposed pipeline on the air emissions indicator are listed in Table 7.2.4-3. These interactions are based on the results of the literature review, desktop analysis, field work, engagement with Aboriginal communities, landowners, stakeholders and the general public (Section 3.0), as well as the professional experience of the assessment team. Mitigation measures summarized in Table 7.2.4-3 were developed in accordance with Trans Mountain standards and accepted pipeline construction methods for construction-related activities.

TABLE 7.2.4-3

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON AIR EMISSIONS

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds				
1.1 Project contribution to emissions	All	RSA	• Trans Mountain will consult with and inform landowners of the potential to be affected by emissions from construction activities prior to commencement of these activities in proximity to the respective landowners [Section 7.0]. • Restrict the duration that vehicles and equipment are allowed to sit and idle to less than one hour, unless air temperatures are less than 0°C [Section 7.0]. • Ensure equipment is well-maintained during construction to minimize air emissions [Section 7.0]. • Use multi-passenger vehicles for the transportation of crews to and from the job sites, where feasible [Section 7.0].	• Increase in air emissions during construction. • Increase in air emissions during site-specific maintenance and inspection activities.
1.2 Dust and smoke during construction	All	RSA	• Trans Mountain will consult with and inform landowners with the potential to be affected by dust emissions from construction activities prior to commencement of these activities in proximity to the respective landowners [Section 8.2]. • Water down construction sites and access roads, when warranted, as directed by Trans Mountain, to reduce or avoid the potential for dust emissions [Section 8.2]. • Conduct burning in accordance with burning permit requirements and A Smoke Management Framework for British Columbia, as applicable. Comply with local government bylaws, the *Forest and Prairie Protection Act* (Alberta), *Open Burning Smoke Control Regulation* (BC) and the *Forest Fire Prevention and Suppression Regulation* (BC) when burning slash [Section 7.0]. • Avoid burning slash in the Lower Mainland where air quality is an issue. Mulch in place or ship/haul slash to an approved disposal location [Section 7.0]. • Limit smoke production during slash disposal by limiting pile size, reducing fuel moisture content, maintenance of loose burning piles free of soil and by using burning sloops or large capacity shredders [Section 7.1]. • Permit burning only when conditions exist that allow for adequate dispersion of smoke so that high concentrations of smoke do not locally affect human health or wildlife. Avoid burning when temperature inversions are present or predicted [Section 8.1].	• Increase in fugitive dust and smoke during construction.

Notes: 1 RSA = Air Quality RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.2.4.5 Potential Residual Effects

The potential residual environmental effects on the air emissions indicator associated with the construction and operations of the pipeline (Table 7.2.4-3) are:

- an increase in air emissions during construction;
- an increase in air emissions during site-specific maintenance and inspection activities; and
- an increase in fugitive dust and smoke during construction.

7.2.4.6 Significance Evaluation of Potential Residual Effects

A combination of a quantitative and qualitative assessment of air emissions was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects. Emissions from Project activities during the construction phase were estimated using available information (Table 7.2.4-2). A qualitative assessment of air emissions during maintenance activities was considered appropriate given the short duration of these activities and anticipated volumes of emissions, relying on the professional judgment of the assessment team.

Table 7.2.4-4 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the proposed pipeline on air emissions. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.4-4

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON AIR EMISSIONS

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds									
1(a) Increase in air emissions during construction.	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant
1(b) Increase in air emissions during site-specific inspection and maintenance activities.	Negative	RSA	Short-term	Periodic	Short-term	Low	High	Moderate	Not significant
1(c) Increase in fugitive dust and smoke during construction.	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant
1(d) Combined effects on the primary emissions of CACs and VOCs indicator (1[a] to 1[c]).	Negative	RSA	Short-term	Periodic	Short-term	Medium	High	Moderate	Not significant

Notes: 1 RSA = Air Quality RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds

The following provides an evaluation of the significance of potential residual effects on the primary emissions of CACs and VOCs indicator.

Increase in Air Emissions During Construction

Participants at the Clearwater and Langley Community Workshops expressed concerns about vehicle emissions during construction and operations. The primary sources of air emissions during construction will be from fuel combustion while transporting crews to and from the work site and along the proposed pipeline corridor, as well as from the operation of heavy equipment required for construction. Implementation of accepted pipeline construction methods as outlined in Table 7.2.4-3 is the preferred approach to reducing air emissions from pipeline construction.

The amount of CAC and VOC emissions associated with construction activities will be reduced by using multi-passenger vehicles for the transportation of crews to and from the job sites, to the extent feasible, as well as using well-maintained equipment. The residual effects of increased air emissions during construction are considered to have a negative impact balance, but they are expected to dissipate within the Air Quality RSA. Ambient concentrations of CAC and VOC are expected to be within provincial objectives and standards (AESRD 2013b, BC MOE 2013a) and, therefore, of medium magnitude. Air emissions resulting from construction activities are considered to be reversible in the short-term (Table 7.2.4-4, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Air Quality RSA – potential increases in air emissions resulting from construction activities will dissipate within the Air Quality RSA.
- Duration: short-term – the event resulting in increased air emissions is construction of the pipeline.
- Frequency: isolated – the event resulting in increases in air emissions (*i.e.*, construction of the pipeline) is confined to a specific period.
- Reversibility: short-term – the residual effects are expected to reverse within less than 1 year for all contaminants after completion of construction.
- Magnitude: medium – an increase in air emissions will occur and may approach but are not expected to exceed environmental or regulatory standards; the increase will be short-lived and localized to the construction area.
- Probability: high – the equipment and vehicles used for construction will emit air contaminants.
- Confidence: moderate – based on a good understanding of the cause-effect relationship but reliant on vehicle and equipment estimates from previous projects.

Increase in Air Emissions During Site-Specific Inspection and Maintenance Activities

Participants at the Clearwater and Langley Community Workshops expressed concerns about vehicle emissions during construction and operation. The primary sources of air emissions during operations will be from fuel combustion while transporting crews to and from the proposed pipeline corridor during site-specific maintenance activities. Aerial patrols along the pipeline segments are unlikely to cause measurable increases of near-surface ambient CAC concentrations above background levels. Furthermore, in the absence of more detailed information, it was assumed that the current frequency and duration of aerial patrols will be sufficient to serve the pipeline expansion associated with the Project.

The amount of air emissions associated with site-specific maintenance activities will be reduced by using multi-passenger vehicles for the transportation of crews to and from the job sites, to the extent feasible, as well as using well-maintained equipment. The residual effects of increased air emissions during site-specific maintenance activities are considered to have a negative impact balance. However, they are expected to dissipate within the Air Quality RSA and be well within provincial objectives and standards (AESRD 2013b, BC MOE 2013a) and, therefore, will be of low magnitude. Air emissions resulting from site-specific inspections and maintenance activities are considered to be reversible in the short-term (Table 7.2.4-4, point 1[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Air Quality RSA – potential increases in air emissions resulting from site-specific maintenance activities (*e.g.*, vegetation management, integrity digs) will dissipate within the Air Quality RSA.
- Duration: short-term – the events resulting in increases in air emissions, are individual maintenance activities (*e.g.*, vegetation management, integrity digs) and each maintenance event will be completed within 1 year.
- Frequency: periodic – maintenance and operations-related activities (*e.g.*, vegetation management, integrity digs) will occur intermittently but repeatedly over the assessment period.
- Reversibility: short-term – the residual effects are expected to reverse within less than 1 year for all contaminants after completion of individual maintenance activities.
- Magnitude: low – periodic increases in air emissions during site-specific maintenance will be detectable but within normal variability of existing conditions with the implementation of proposed mitigation measures.

- Probability: high – the equipment and vehicles used for site-specific activities (*e.g.*, vegetation management, integrity digs) will emit air contaminants.
- Confidence: moderate – based on a good understanding of the cause-effect relationship and reliable data from current pipeline operations in the same regions; however, detailed information on equipment and vehicle usage for site-specific activities and the duration and frequency of future aerial patrol are not available.

Increase in Fugitive Dust and Smoke During Construction

Smoke will be associated with the burning of slash along discrete segments of the proposed pipeline corridor. In accordance with applicable provincial legislation pertaining to mulching depth requirements, not all non-merchantable timber can be disposed of by mechanical means; therefore, slash burning is required. Since the maximum depth of mulch will not exceed 5 cm or will be in accordance with the applicable provincial legislation, whichever is less, any remaining vegetation and non-salvageable timber not retained for rollback will be burned. The impact balance of this potential residual effect is considered to be negative since smoke could reduce local air quality. In some areas of BC, burning restrictions may be a concern in the summer when the risk of fire is high, as noted by participants of the Blue River Community Workshop. Participants in the Clearwater and Langley Community Workshops were also concerned about smoke from burning during construction. In the Lower Mainland, air quality is an issue and burning slash will be avoided. This residual effect is reversible immediately or in the short-term after cessation of burning, depending on the size of the slash piles and conditions during burning, and of medium magnitude given the anticipated volume of slash along the proposed pipeline corridor.

Emissions of particulate matter related to earth moving activities and use of heavy equipment during pipeline construction are expected to be greater than particulate matter emissions during pipeline operation. Fugitive dust from equipment travelling on disturbed soil can be a major dust contributor during dry summer periods. An increase in dust on unpaved access roads will be confined to construction and reclamation activities completed during relatively dry, non-frozen conditions. Implementing accepted pipeline construction methods as outlined in Table 7.2.4-3 is the preferred approach to reducing air emissions from pipeline construction.

The impact balance of this potential residual effect is considered to be negative since dust and smoke could reduce air quality. Larger particles of fugitive dust and smoke will settle out via gravitational settling within a relatively short timeframe at any given location, while finer particles might remain suspended for more than two days. Therefore, this residual effect is reversible in the short-term. With the implementation of the recommended mitigation measures provided in Table 7.2.4-3, fugitive dust and smoke during construction will be reduced. However, under some environmental conditions, the residual effect may still approach provincial objectives and standards (AESRD 2013b, BC MOE 2013a); therefore, its magnitude is rated as medium (Table 7.2.4-4, point 1[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Air Quality RSA – potential increases in dust and smoke resulting from construction may extend beyond the Footprint and into the Air Quality RSA.
- Duration: short-term – the event resulting in increases in dust and smoke is construction of the pipeline.
- Frequency: isolated – the event resulting in increases in dust and smoke (*i.e.*, construction of the pipeline) is confined to a specific period.
- Reversibility: short-term – the effects are expected to reverse within several days once construction or the maintenance activity is complete.
- Magnitude: medium – a small volume of slash along the proposed pipeline corridor is expected, and the mitigation measures provided in Table 7.2.4-3 will reduce fugitive dust and smoke during construction.
- Probability: high – disposal of slash by burning is planned, unpaved roads will be used to access the right-of-way, and construction and maintenance activities will occur during non-frozen conditions.

- Confidence: moderate – based on a good understanding of the cause-effect relationship, but the quantification of fugitive dust and smoke emissions (*e.g.*, from slash burning) is based on data from outside the Project and reliable data for slash burning in the Project data are unavailable.

Combined Effects on Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds

An evaluation of the combined effects considers those residual effects that are likely to occur. The potential exists for increases in air emissions to occur simultaneously with increases in fugitive dust and smoke during construction. The combined effects of pipeline construction on CACs and VOCs are reversible in the short-term and of low to medium magnitude (Table 7.2.4-4, point 1[d]). A summary of the rationale for all of the significance criteria of combined effects on primary emissions of CACs and VOCs is provided below.

- Spatial Boundary: Air Quality RSA – combined effects on air emissions from construction will dissipate within the regional airshed.
- Duration: short-term – the event causing combined effects on air emissions is construction of the pipeline.
- Frequency: periodic – the events causing combined effects on air emissions (*i.e.*, construction and site-specific inspection and maintenance activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short-term – combined effects are expected to reverse within several days once construction or inspection and maintenance activities are complete.
- Magnitude: medium – the implementation of the proposed mitigation measures is expected to effectively reduce combined effects on air emissions, but under certain environmental conditions, provincial ambient air quality objectives and standards may be approached.
- Probability: high – disposal of slash by burning is planned, unpaved roads will be used to access the right-of-way, and construction and maintenance activities will occur during non-frozen conditions.
- Confidence: moderate – based on a good understanding of the cause-effect relationship; however, where reliable Project data were unavailable, outside data were used.

7.2.4.7 Summary

As identified in Table 7.2.4-4, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on air emissions indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline construction and operations on air emissions will be not significant.

7.2.5 Greenhouse Gas Emissions

This subsection describes the potential Project effects on greenhouse gas (GHG) emissions. The Air Quality and Greenhouse Gas Technical Report of Volume 5C provides further information pertaining to GHG emissions associated with the construction and operation of the Project.

The assessment of effects on GHG emissions has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, Westridge Marine Terminal and pipeline reactivation), since GHG emissions associated with the construction and operation of each Project component are aggregated for the Project as a whole and then compared to provincial and federal GHG inventory totals.

7.2.5.1 Assessment Indicators and Measurement Endpoints

The assessment indicators selected for use in the assessment of Project related activities on GHG emissions are listed in Table 7.2.5-1. Selection of indicators for GHG emissions considered: filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues; feedback from Aboriginal engagement, regulatory authorities, and stakeholders; available research literature; and the professional judgment of the assessment team. The proposed GHG indicators were discussed during the Edmonton, Kamloops and Surrey ESA Workshops. There was general consensus among workshop participants that the proposed GHG emissions indicators were appropriate for evaluating effects of Project related activities on GHG emissions and the effect of these emissions on the environment. Input on indicator selection was sought from Environment Canada, BC MOE, FVRD, Metro Vancouver and PMV (Section 3.0); no additional indicators were suggested for consideration in assessment of Project related activities.

Both quantitative and qualitative measurement endpoints are applied to assess potential effects of Project related activities on the GHG indicators.

Three GHGs (carbon dioxide [CO_2], methane [CH_4], and nitrous oxide [N_2O]) are explicitly considered in the GHG emission indicators. GHGs accumulate in the atmosphere and have the potential to contribute incrementally to climate change on a global scale (NRC 2011). Therefore, the terrestrial effects assessment of GHG emissions is based on total Project related construction activities and annual total Project related operation activities.

Among other GHGs, only emissions of SF_6 (sulfur hexafluoride) and black carbon are expected from Project construction and operations. SF_6 emissions occur in the context of power generation and transmission and are incorporated in the estimation of GHG emissions from the Project through provincial emission factors for consumed electrical energy. Black carbon will be emitted mostly from burning associated, for example, with land clearing. However, regional, provincial and federal legislation (Metro Vancouver 2011a; AENV 2004; BC MOE 2013a; Government of Canada 2013) currently do not recognize black carbon as a GHG. This is partly due to evolving scientific understanding of the role of black carbon in the global climate system.

Federal and provincial legislation are in place to address GHG emissions. All facilities emitting more than 50,000 tonnes of GHGs are required to submit a report under Environment Canada's *Greenhouse Gas Emissions Reporting Program* (Environment Canada 2013a). Facilities in Alberta emitting more than 50,000 tonnes of GHGs are also required to submit reports under AESRD's *Specified Gas Reporting Regulation* (AENV 2004); for facilities emitting more than 100,000 tonnes, verification is required. BC's *Reporting Regulation under the Greenhouse Gas Reduction (Cap and Trade) Act* sets out the requirements for reporting GHG emissions from BC facilities emitting 10,000 tonnes or more of GHGs (BC MOE 2013a). Facilities emitting 25,000 tonnes or more are required to have emissions reports verified by a third party.

Note that no absolute GHG emission limits are set by the legislation discussed in the previous paragraph. Therefore, the following numbers are provided for comparison, only. Environment Canada's National Inventory Report estimates total GHG emissions from Canada to be 702 Mt in 2011. Of the 702 Mt, 242.0 Mt, and 59.1 Mt were Alberta and BC's contributions, respectively (Environment Canada 2013b).

TABLE 7.2.5-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR GHG EMISSIONS

GHG Emissions Indicators	Measurement Endpoints	Rationale for Indicator Selection
Emissions of CO_2, CH_4 and N_2O	• Emissions of CO_2e (carbon dioxide equivalent) from Project construction and comparison to local, provincial and national totals. • Emissions of CO_2e from Project operation and comparison to local, provincial and national totals.	The selection of the indicator and measurement endpoints considered NEB *Filing Manual* requirements for the GHG emissions element under Table A-2, addressed concerns raised through Aboriginal engagement and stakeholder consultation and are supported by regulatory authorities (*i.e.*, Environment Canada, BC MOE, Metro Vancouver, FVRD and PMV).
Effect on overall climate change	• Effects of CO_2e emissions from Project construction on change in environmental parameters such as global average temperatures. • Effects of CO_2e emissions from Project operation on change in environmental parameters such as global average temperatures.	

7.2.5.2 Spatial Boundaries

Greenhouse gas emissions have a global effect that cannot easily be measured on a local or regional scale. The spatial boundary for GHG is therefore beyond regional (*i.e.,* international) and encompasses all sources of GHG emissions from the Project.

7.2.5.3 GHG Emissions Associated with Individual Project Components

The methods and assumptions used to calculate the GHG emissions associated with the construction and operations of the Project are provided in the Air Quality and Greenhouse Gas Technical Report of Volume 5C.

<u>GHG Emissions Associated with Pipeline Construction and Operations</u>

During the construction phase, land clearing for construction right-of-way and facilities, operation of vehicles and equipment, and other construction activities will result in GHG emissions. During operation of the pipeline, the main sources of GHG emissions will be regular transportation and equipment use during maintenance activities. Pipeline related GHG emissions are summarized in Table 7.2.5-2.

Emissions from pipeline construction activities were estimated using available information. All pipeline construction emissions will be intermittent and limited in duration. Since the construction schedule is subject to change, construction related emissions were not estimated on an annual basis. Instead, these emissions are estimated and reported as overall totals. Emissions associated with pipeline operation occur periodically over the life of the operating pipeline and were estimated as annual totals.

More than 90% of all estimated construction emissions are expected from land clearing. GHG emissions during pipeline operations are not expected to change from existing operations. In the absence of specific information, it is assumed that the current frequency of aerial patrols will suffice to also cover the expanded pipeline. Emissions associated with maintenance activities include combustion products from fossil fuel use for space heating and vehicle operation. These emissions could not be broken down into specific facilities or components, and therefore, no appropriate scaling of these emissions to account for the pipeline expansion could be established. It is expected, however, that the annual operation emissions will be small compared to total construction emissions.

TABLE 7.2.5-2

GHG EMISSIONS GENERATED BY PIPELINE CONSTRUCTION AND OPERATIONS

	Pipeline-Related Activity	GHG Emissions (t CO_2e)
Construction (total)	Land clearing	831,000
	Operation of construction equipment	68,530
Construction subtotal		899,500
Operation (annual)	Maintenance and inspection activities	Negligible

<u>GHG Emissions Associated with Temporary Facilities Construction and Operations</u>

During the construction of temporary facilities, site preparation, operation of vehicles and equipment, and other construction activities will result in GHG emissions. During operation of the temporary facilities, GHG emissions are caused by transportation and activities associated with the residence of workers (*e.g.,* space heating and electricity use). All GHG emissions associated with construction and operation of temporary facilities will be intermittent and limited in duration to the construction phase of the Project.

Information on construction and operation activities for temporary facilities was not available separately from construction activities for permanent facilities and pipelines. Therefore, associated GHG emissions are estimated as total construction-related emissions for permanent and temporary facilities.

<u>GHG Emissions Associated with Pump Station Construction and Operations</u>

During the construction phase, land clearing for pump station facilities and associated power lines, site preparation, operation of vehicles and equipment, and other construction activities will result in GHG emissions. During operation of the pump stations, direct GHG emissions are caused by fuel combustion for space heating, and fugitive emissions from valves, connectors, and pumps. Electricity consumption by the pump assemblies will result in indirect GHG emissions. Pump station related GHG emissions are summarized in Table 7.2.5-3.

In the absence of information on construction activities in pump stations, GHG estimates of construction equipment use from previous projects were used as a basis to estimate construction related emissions at pump stations. Emissions from land clearing were not estimated since these are location specific. All construction emissions will be intermittent and limited in duration. Since the construction schedule is subject to change, construction related emissions were not estimated on an annual basis. Instead, these emissions are estimated and reported as overall totals. Emissions associated with pump station operation occur continuously over the life of the operating pump stations and were estimated as annual totals. However, for the assessment of overall Project effects on climate change, the total cumulative emissions over the 50 year period are represented.

GHG emissions from equipment use for pump station construction are expected to be of the same order of magnitude as emissions from pipeline construction. This is a reasonable result given that the Footprint of the pump stations is smaller than that of the pipeline but the construction effort per station is greater. Note that no additional land clearing specifically for the construction of pump stations is taken into consideration beyond land clearing required for the pipeline right-of-way because the early engineering design did not provide enough information to estimate the required clear cutting for pump stations, but it is expected to be small compared to conservatively high estimates for pipeline land clearing.

The greatest source of GHG emissions across all construction and operation activities associated with the Project is indirect emissions from the use of electricity to operate the pump assemblies at pump stations. The conservatively high estimate (assuming pump operations at maximum capacity all the time) is 1.069 Mt CO_2e of indirect GHG emissions per year. All other operational GHG emissions at pump stations are much lower than the uncertainties in the estimates of the indirect emissions.

TABLE 7.2.5-3

GHG EMISSIONS GENERATED BY PUMP STATION CONSTRUCTION AND OPERATIONS

	Pump Station Related Activity	GHG Emissions (t CO_2e)
Construction (total)	Operation of construction equipment	49,790
Operation (annual)	Fuel combustion for space heating	115.1
	Fugitive emissions	14.3
	Electricity consumption	1,069,000
Operation subtotal		1,069,000

GHG Emissions Associated with Tank Installation and Operations

During the installation of the proposed tanks and associated terminal work, site preparation, operation of vehicles and equipment, and other construction activities will result in GHG emissions. During operations, the main sources of direct GHG emissions will be regular transportation and equipment use during maintenance activities and normal operations, as well as fugitive emissions from working and standby losses from storage tanks and the fugitive emissions from the corresponding valves and connectors. Electricity consumption at the terminals, mainly by the booster pumps, will result in large amounts of indirect GHG emissions. Assuming that these pumps will be working at full capacity at all times, a conservative estimate of emissions from the operation of the storage tanks is approximately 58.5 kt CO_2e emissions. Tank-related GHG emissions are summarized in Table 7.2.5-4.

Emissions from tank installation activities were estimated using available information. All construction emissions will be intermittent and limited in duration. Since the construction schedule is subject to change, construction related emissions were not estimated on an annual basis. Instead, these emissions are estimated and reported as overall totals. Emissions associated with operation of tanks occur continuously over the life of the operating tanks and were estimated as annual totals.

GHG emissions from equipment use for tank installation are expected to be of the same order of magnitude as emissions from pump station construction. It is assumed that no land clearing is required for tank installation. Fugitive GHG emissions are higher at tanks than pump stations, but are small compared to most other operational emissions at facilities and components. No information was available to estimate an increase, if any, of GHG emissions associated with maintenance activities (*e.g.*, fossil fuel combustion for vehicle operation and space heating). It is expected that the increase in these emissions is small compared to total construction emissions, and annual electricity-related emissions.

TABLE 7.2.5-4

GHG EMISSIONS GENERATED BY TANK INSTALLATION AND OPERATIONS

	Tank Installation Related Activity	GHG Emissions (t CO_2e)
Construction (total)	Operation of construction equipment	26,370
Operation (annual)	Personnel transportation	Negligible
	Fuel combustion for space heating	Negligible
	Fugitive emissions	32.1
	Electricity consumption	58,460
Operation subtotal		58,490

GHG Emissions Associated with Westridge Marine Terminal Construction and Operations

During the construction phase at the Westridge Marine Terminal, dredging, dewatering, and other construction activities as well as the operation of vehicles and product loading will result in GHG emissions. During the operations phase, most of the GHG emissions associated with the Westridge Marine Terminal will result from fugitives released during vapour combustion and product loading. Regular transportation, space heating, and equipment use during maintenance activities and normal operations, as well as fugitive emissions from storage tanks, associated valves and connectors, and ship holds are also sources of direct GHG emissions. Electricity consumption at the terminal will result in indirect GHG emissions. GHG emissions related to the construction and operations of the Westridge Marine Terminal are summarized in Table 7.2.5-5.

Emissions from activities at the Westridge Marine Terminal were estimated using available information. All construction emissions will be intermittent and limited in duration. Since the construction schedule is subject to change, construction-related emissions were not estimated on an annual basis. Instead, these emissions are estimated and reported as overall totals. Emissions associated with operation of tanks are expected to occur continuously over the life of the operating terminal and were estimated as annual totals.

Construction-related GHG emissions at the Westridge Marine Terminal are less than those at other facilities and components but are of a similar order of magnitude. This is reasonable given the smaller scope and spatial extent of construction at the Westridge Marine Terminal.

Fugitive emissions from ships at berth are considered to be terrestrial operation emissions at the Westridge Marine Terminal. Combustion of about 90% of these fugitive emissions with a VCU is currently a substantial source of GHG emissions at the Westridge Marine Terminal. These emissions will be reduced by nearly 45 kt CO_2e after the installation of vapour recovery units (VRU), and new removal media, combined with the standby VCU. No information was available to estimate an increase, if any, of GHG emissions associated with maintenance activities, space heating, and electricity consumption. It is expected that the increase in these emissions is small compared to the decrease in GHG emissions related to ship fugitive emissions.

TABLE 7.2.5-5

GHG EMISSIONS GENERATED BY CONSTRUCTION AND OPERATIONS OF THE WESTRIDGE MARINE TERMINAL

	Westridge Marine Terminal Related Activity	GHG Emissions (t CO_2e)
Construction (total)	Operation of construction equipment	10,120
Operation (annual)	Personnel transportation	Negligible
	Fuel combustion for space heating	Negligible
	Vapour flaring of fugitive emissions from tanker loading and uncaptured fugitive emissions	-44,740
	Electricity consumption	Negligible
Operation subtotal		-44,740

GHG Emissions Associated with Pipeline Reactivation Activities

During operation of the reactivated pipeline segments, the main sources of GHG emissions will be regular transportation and equipment use during maintenance activities. Pipeline reactivation related GHG emissions are summarized in Table 7.2.5-6. These emissions occur periodically over the life of the operating pipeline and were estimated as annual totals. No information was provided to estimate GHG emissions during reactivation and associated activities such as the installation of automated valves, but can be assumed to be small compared to emissions during operations of the reactivated pipeline.

TABLE 7.2.5-6

GHG EMISSIONS GENERATED BY PIPELINE REACTIVATION

	Pipeline Reactivation Related Activity	GHG Emissions (t CO_2e)
Operation (annual)	Maintenance and inspection activities	Negligible

GHG Emissions Associated with Facilities Located Within Pipeline Right-of-Way

Some elements interact with associated pipeline facilities (*e.g.*, block valves) within the proposed pipeline right-of-way. No information was available to quantify potential GHG emissions from these facilities, but if GHG emissions occur, they are expected to be negligible compared to other GHG emissions from Project-related activities.

7.2.5.4 Potential Effects and Mitigation Measures

Effects Considerations

Burning of timber associated with land clearing will emit black carbon. Provincial and federal legislation currently does not recognize black carbon as a GHG, partly due to evolving scientific understanding of the role of black carbon in the global climate system. Consequently, emissions of black carbon were scoped out of the effects assessment of GHG emissions.

Identified Potential Effects

Potential effects associated with the construction and operation of the Project on the GHG emissions indicators are listed in Table 7.2.5-7. These interactions are based on the results of the literature review, desktop analysis, engagement with Aboriginal communities, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.2.5-7 was principally developed in accordance with Trans Mountain standards on the basis of industry best practices, professional judgment of the assessment team, and experience from previous projects.

TABLE 7.2.5-7

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON GHG EMISSIONS

Potential Effect	Project Components	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
1. GHG Emissions Indicator – Emissions of CO_2, CH_4, and N_2O				
1.1 Increase in CO_2e emissions	New Pipeline Segments Temporary Facilities Pump Stations including power lines Terminals Westridge Marine Terminal Pipeline Reactivation	International	• Restrict the duration that vehicles and equipment are allowed to sit and idle to less than one hour, unless air temperature is less than 0°C [Section 7.0]. • Ensure equipment is well-maintained during construction to minimize air emissions and unnecessary noise [Section 7.0]. • Use multi-passenger vehicles for the transportation of crews to and from the job sites, to the extent feasible [Section 7.0].	• Increase in CO_2e emissions.
2. GHG Indicator – Effect on Overall Climate Change				
2.1 Changes in environmental parameters (*e.g.,* increase in global average temperature)	New Pipeline Segments Temporary Facilities Pump Stations including power lines Terminals Westridge Marine Terminal Pipeline Reactivation	International	• Restrict the duration that vehicles and equipment are allowed to sit and idle to less than one hour, unless air temperature is less than 0°C [Section 7.0]. • Ensure equipment is well-maintained during construction to minimize air emissions and unnecessary noise [Section 7.0]. • Use multi-passenger vehicles for the transportation of crews to and from the job sites, to the extent feasible [Section 7.0].	• Changes in environmental parameters (*e.g.,* increase in global average temperature).

Note: 1 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.2.5.5 Potential Residual Effects

The potential residual environmental effects on GHG indicators associated with Project related activities are (Table 7.2.5-7):

- an increase in CO2e emissions; and
- changes in environmental parameters (*e.g.*, increase in global average temperature).

7.2.5.6 Significance Evaluation of Potential Residual Effects

A combined quantitative and qualitative analysis was undertaken to evaluate the significance of the potential residual environmental effects for GHG emission indicators as these changes over the existing data were quantifiable and this approach was preferable based on discussions with federal, provincial and local regulatory authorities. Changes over the existing conditions were quantifiable and details on the calculations are summarized in the Air Quality and Greenhouse Gas Technical Report (Volume 5C). However, there are no standards, guidelines, objectives or other established and accepted thresholds to define quantitative rating criteria for GHG emissions or changes in environmental parameters. Therefore, the magnitude was evaluated qualitatively based on available research literature and professional judgment.

Table 7.2.5-8 provides a summary of the significance evaluation of the potential residual environmental effects of an increase in Project related construction and operation activities on the GHG emissions indicators. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.5-8

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATION ON GHG EMISSIONS

Potential Effect	Impact Balance	Spatial Boundary	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[1]
1. GHG Emissions Indicator – Emissions of CO_2, CH_4, and N_2O									
1(a) Increase in CO_2e emissions.	Negative	International	Short to long-term	Isolated to continuous	Permanent	Low	High	Moderate	Not significant
2. GHG Emissions Indicator - Effect on Overall Climate Change									
2(a) Changes in environmental parameters (*e.g.*, increase in global average temperature).	Negative	International	Short to long-term	Isolated to continuous	Permanent	Negligible	High	High	Not significant

Note: 1 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

GHG Emissions Indicator - Emissions of CO_2, CH_4, and N_2O

The following provides the evaluation of significance of potential residual effects on the emissions of CO_2, CH_4 and N_2O indicator.

Increase in CO_2e Emissions

Project emissions of GHG are summarized and compared with provincial and national emissions in Table 7.2.5-9. Note that construction emissions are only reported as overall totals for the entire construction period and, therefore, cannot be directly compared with provincial and national emissions which are reported annually. GHG emissions were estimated based on the most appropriate and conservative assumptions about Project activities where detailed information was unavailable.

Mitigation measures are provided in Table 7.2.5-7. Their implementation ensures that GHG emissions during construction are comparable to emissions of similar projects. Construction activities are of short-term duration and, therefore, of less concern for stakeholders than long-term operation emissions. Mitigation measures will reduce direct GHG emissions from maintenance and service activities during operation of the Project. The vast majority of annual operation emissions are indirect emissions from electricity use by the pump assemblies. The pumps are specified to operate as closely as possible to maximum efficiency. GHG emissions will cease immediately when Project activities stop and are, therefore, immediately reversible.

In 2011, Canada had total GHG emissions of 702 Mt of CO_2e as reported in the National Inventory Report 1990-2011 (Environment Canada 2013b). Alberta's contribution to national GHG emissions in 2011 was 242 Mt CO_2e, which is 34.5% of total Canadian emissions, while BC had 59.1 Mt of CO_2e emissions, corresponding to 8.4% of national emissions. Project operations in Alberta will result in a 0.46% increase in provincial emissions. In BC, the decrease in emissions will be 0.05%. Total Project operations are estimated to result in a 0.15% increase on Canada's national GHG emissions. While the GHG emissions are quantifiable, they are of low magnitude compared to provincial and federal total annual emissions.

TABLE 7.2.5-9

TOTAL GHG EMISSIONS GENERATED BY PROJECT CONSTRUCTION AND OPERATIONS

	Total Project Construction Emissions (t CO_2e)	Annual Project Operation Emissions (t CO_2e)	Provincial and Canadian Annual Emission Totals (2011) (t CO_2e)	Change in Provincial and Canadian Annual Emission Totals Caused by Project Operations
Alberta	176,900	1,114,000	242,000,000	0.46%
BC	808,800	-30,930	59,100,000	-0.05%
Total	985,800	1,083,000	702,000,000 (Canada)	0.15%

Events associated with the construction of the pipeline, pump stations, (including power lines), installation of the storage tanks, and expansion of the Westridge Marine Terminal as well as operation of temporary facilities and pipeline reactivation activities are limited to the duration of the construction phase and, therefore, isolated. Conversely, operation-related events for maintenance and inspection, building space heating and electricity use, and vapour combustion and vessel loading at the Westridge Marine Terminal are expected to occur periodically over the life of the operating terminal. Finally, electricity use by pump assemblies will occur continuously over the life of the operating facilities. A summary of the rationale for all of the significance criteria is provided below (Table 7.2.5-8, point 1[a]).

- Spatial Boundary: international – Project emissions of GHG disperse globally.
- Duration: short to long-term – the events causing Project emissions of GHG occur over a range of durations, from short-term for construction to long-term for operation activities of Project components.
- Frequency: isolated to continuous – the events causing Project emissions of GHG occur over a range of frequencies, from isolated construction events to periodic (*e.g.* maintenance and inspection activities) and continuous events (*e.g.,* fugitive emissions) during Project operations.
- Reversibility: permanent – Project emissions will result in a permanent addition to global GHG. Emissions of GHG cease immediately when Project activities end.
- Magnitude: low – Project emissions of GHG can be estimated and will be detectable. Total Project operations are estimated to result in a 0.35% increase on Canada's national GHG emissions. In the absence of environmental or regulatory emission limits for GHG emissions, the magnitude is rated as low.
- Probability: high – Project-related activities will result in emissions of GHG.
- Confidence: moderate – residual effects assessment is based on a good understanding of cause-effect relationships between the Project and GHG emissions; however, equipment-specific data are limited and, in some cases, obtained from outside the Project.

GHG Emissions Indicator – Effect on Overall Climate Change

The following provides the evaluation of significance of potential residual effects on the overall climate change indicator.

Changes in Environmental Parameters

The National Research Council (NRC) in its report on climate stabilization targets (NRC 2010), based on the most current modelling results, evaluated an approximately linear warming per cumulative emissions ranging from roughly 0.27°C to 0.68°C per 1,000,000 Mt CO_2e, or roughly 20 years of 2010 annual global GHG emissions. A best representative estimate of 0.47°C per 1,000,000 Mt CO_2e is selected as the climate response to cumulative GHG emissions. The NRC further pointed out that other changes in the climate system and physical environment (*e.g.,* precipitation changes and decreases in crop yields) are likewise proportional to cumulative GHG emissions. It is further noted, that these changes last over very long periods of time and, therefore, are practically permanent.

On the basis of these expected changes per cumulative GHG emissions, the effect of the Project on climate change can estimated. Assuming that the operation-related emissions will stay the same over the life of the operating pipeline and associated facilities, total estimated Project emissions, including construction emissions and operation emissions over a 50 year period, will add up to 55.1 Mt CO_2e. The effects of these emissions on global temperature and other environmental parameters are presented in Table 7.2.5-10.

TABLE 7.2.5-10

EFFECT OF THE PROJECT ON OVERALL CLIMATE CHANGE

Change in Environmental Parameter	Best Estimate
Global warming (°C)	2.6×10^{-5}
Precipitation changes (%)	±0.00022
Increase in heavy rainfall (%)	0.00021
Yield reduction in a number of crops (%)	0.00032
Changes in streamflows (%)	±0.00022
Decrease in the extent of annually averaged Arctic sea ice (%)	0.00058
Decrease in the extent of September Arctic sea ice (%)	0.00058

Although these effects can be estimated, they are approximately five orders of magnitude smaller than natural year-to-year variability or variations due to local microclimate changes. The estimated changes in Table 7.2.5-10 cannot be measured and, therefore, the magnitude is rated negligible. Local or regional changes of climate that may be of concern to stakeholders are caused by the sum of all global GHG emissions and, therefore, require international initiatives to reduce overall climate change.

Mitigation measures to reduce potential effects of all Project-related activities on overall climate change are the same as for the potential effects of all Project-related activities on GHG emissions as listed in Table 7.2.5-7. Their implementation ensures that the effects on overall climate change during construction are comparable to those of similar projects.

The events during construction of the pipeline, pump stations (including power lines), installation of the storage tanks, and expansion of the Westridge Marine Terminal as well as operation of temporary facilities and pipeline reactivation activities are limited to the duration of the construction phase, and therefore, are considered short-term. Operation-related events that cause climate change effects are expected to occur over the life of the operating pipeline and associated facilities and, therefore, are considered long-term.

The events associated with the construction of the pipeline, pump stations (including power lines), installation of the storage tanks, and expansion of the Westridge Marine Terminal as well as operation of temporary facilities and pipeline reactivation activities are limited to the construction phase and, therefore, are considered to be isolated in frequency. Maintenance and inspection activities, building space heating and electricity use, and fugitive vapour combustion from vessel loading at the Westridge Marine Terminal are expected to occur periodically (intermittently but repeatedly) over the life of the operating pipeline and associated facilities. Finally, fugitive GHG emissions and electricity use by pump assemblies are expected to occur continuously over the life of the operating pipeline and associated facilities.

The modelling results in NRC (2010) show no substantial decrease in the change of environmental parameters presented in Table 7.2.5-10 for hundreds to thousands of years; therefore, reversibility is effectively permanent.

A summary of the rationale for all of the significance criteria is provided below (Table 7.2.5-8, point 2[a]).

- Spatial Boundary: international – effects on climate change are global in nature.
- Duration: short to long-term – the events resulting in potential effects on climate change occur over a range of durations, from short-term construction to long-term operations events.

- Frequency: isolated to continuous – the events resulting in potential effects on climate change occur over a range of frequencies from isolated construction activities to continuous electricity use by pump assemblies.
- Reversibility: permanent – potential effects on climate change are considered irreversible.
- Magnitude: negligible – changes in environmental parameters (*e.g.*, increase in global average temperature) resulting from Project-related activities are not detectable from existing (baseline) climate variability.
- Probability: high – Project-related activities will contribute, albeit a small amount, to global GHG emissions and resultantly global climate change.
- Confidence: high – determination of significance is based on a good understanding of cause-effect relationships between GHG emissions from Project activities and overall climate change. Observational and numerical modelling data also support the significance determination.

7.2.5.7 Summary

As identified in Table 7.2.5-8, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on GHG emissions indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of Project construction and operation on GHG emissions will not be significant.

7.2.6 Acoustic Environment

This assessment considers both sound and vibrations as components of the Acoustic Environment. The Project will employ heavy equipment for construction of the Project and mechanical equipment for the tanks, pump stations and Westridge Marine Terminal operations. These are all sources of sound that may change the acoustic environment at sensitive locations (primarily places people live) and so are evaluated in the assessment of Project effects. Similarly, blasting may be required for pipeline construction which may generate vibrations at sensitive locations. This subsection evaluates the effects due to the Project on the Acoustic Environment.

7.2.6.1 Assessment Indicators and Measurement Endpoints

Assessment indicators identified for the acoustic environment element are sound levels and vibrations. Sound levels refer to the amount of sound in the outdoor environment, as may be experienced by people or wildlife. Vibrations refer to airborne or ground borne vibrations that occur from blasting, as may be experienced by people or wildlife. Assessment indicators and measurement endpoints for acoustic environment are listed in Table 7.2.6-1.

The NEB *Filling Manual* also requires that potential for cumulative effects with residual sound be evaluated. Specific noise criteria are not cited in the NEB *Filing Manual*, however, the guidance provided specifically refers to the Alberta Energy Regulator (AER) and BC Oil and Gas Commission (OGC) noise limits. Though not specifically referenced in the NEB *Filing Manual*, the Health Canada guidance can be used to provide context around sound level changes, specifically in urban areas with multiple receptors.

The assessment indicators and endpoints for sound in the acoustic environment are those defined in AER *Directive 038: Noise Control* (Alberta Energy Resources Conservation Board [ERCB] 2007) and the BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009). These methods are focussed on the human environment, specifically residences.

The indicators for the acoustic environment are sound levels, specifically at noise sensitive receptors. As defined in AER *Directive 038* and the BC OGC *Noise Control Best Practices Guideline*, noise sensitive receptors are any dwelling or residence occupied at least six weeks per year within 1.5 km of the Project Footprint. From the wildlife perspective, noise sensitive receptors are habitat areas where sensitive species are present.

Since both Alberta and BC do not have generally accepted guidelines for the evaluation of airborne/ground-borne vibration, guidance from another Canadian province was used. The *Cautionary Limit from the Noise Pollution Control Publication 119 (NPC-119)* by the Ontario Ministry of Environment (ON MOE) guidance was found to be the most stringent, therefore, was used to compare against the calculations of airborne/ground-borne vibration from blasting for the Project.

No direct feedback regarding noise indicators was received from the ESA Workshops, except that some participants sought assurance that existing provincial requirements were to be used. Since the provincial noise requirements are well defined, there was no additional consultation with provincial regulatory authorities about the indicators. PMV was consulted, as ports are federal facilities that are not required to meet provincial or municipal regulations or guidance. PMV noted that it has no specific noise criteria but generally follows Health Canada and municipal bylaws regarding noise issues. BC and Alberta provincial requirements as well as Health Canada and municipal bylaws are all considered in the assessment.

Endpoints represent measureable attributes of the assessment endpoints that can be quantified, predicted and compared to existing conditions, guidelines or other similar criteria suitable for evaluating change. One endpoint from the AER/BC OGC criteria has been selected for sound in the acoustic environment:

- the energy equivalent (L_{eq}) sound level measured in A-weighted decibels.

Two endpoints from the ON MOE NPC-119 criteria have been selected for the airborne and ground-borne vibration acoustic environment:

- the Peak Pressure Level or L_{peak} measured in linear (un-weighted) decibels (airborne); and
- the Peak Particle Velocity or PPV measured in millimeters per second (ground-borne).

TABLE 7.2.6-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR ACOUSTIC ENVIRONMENT

Acoustic Environment Indicators	Measurement Endpoints	Rationale for Indicator Selection
Sound levels	• Energy equivalent (Leq) sound level measured in A-weighted decibels	Indicator as defined by the assessment methods cited under the acoustic environment element in Table A-2 of the NEB *Filing Manual*.
Vibration	• Peak Pressure Level or Lpeak measured in linear (un-weighted) decibels • Peak Particle Velocity or PPV measured in millimeters per second	Both indicators are used to define the potential affects from blasting. Methods from ON MOE used in absence of guidance in other documentation.

7.2.6.2 Spatial Boundaries

The spatial boundaries used in the effects assessment of acoustic environment considered one or more of the following areas:

- a Footprint Study Area (as defined in Section 7.1.3);
- an Acoustic Environment LSA; and
- an Acoustic Environment RSA.

As defined in AER *Directive 038* and the BC OGC *Noise Control Best Practices Guideline*, the Acoustic Environment LSA is defined as 1.5 km from the fenceline or Footprint of the Project. For construction, this includes the pipeline, pump stations and terminals. For operations, this includes the pump stations and terminals only.

In the absence of a setback distance listed in the Health Canada guidance document, the AER and BC OGC criteria was used at all locations. The AER and BC OGC criteria require that noise be controlled at the 1.5 km distance from the fenceline or Footprint. Therefore, potential effects of the Project on human receptors are not anticipated to extend beyond the Acoustic Environment LSA, however, cumulative effects from other developments could occur within 1.5 km of those other developments, so an Acoustic Environment RSA of 5 km is considered. Vibration levels are discussed within the Acoustic Environment RSA, which is the area potentially affected by construction vibration, consisting of a 10 km wide band extending from the proposed pipeline corridor (*e.g.,* Footprint plus 5 km on both sides of the proposed pipeline corridor). The Acoustic Environment RSA is shown in Figures 5.4-1 to 5.4-4.

The Acoustic Environment LSA and RSA for sound levels were discussed during the ESA Workshops held in March 2013. No specific comments or suggestions were received regarding the sound level LSA and RSA boundaries.

7.2.6.3 Acoustic Environment Context

The acoustic environment will vary based on the level of development and geography along the proposed pipeline corridor. Human developments, the presence of infrastructure, the amount of foliage, the density of wildlife and weather all influence sound level in the outdoor environment. It is normal for sound levels to fluctuate over the course of a day or night, with the amount and timing of those fluctuations being influenced by the local sources of sound.

The proposed pipeline corridor travels through varying levels of human development, such as urban, sub-urban, rural and unoccupied areas. Urban and sub-urban areas will be influenced by people's daily activities and local industry. Rural areas are influenced by local infrastructure (*e.g.,* traffic or trains) and existing pipeline sources (*e.g.,* pump stations or maintenance activities) equally with the natural environment while the natural environment dominates in undeveloped areas. Noise will have greater natural fluctuations in rural and undeveloped areas. Urban areas will have more consistent sound levels over time, but also higher sound levels due to the level of local activity.

The AER *Directive 038* and BC OGC *Noise Control Best Practices Guideline* used as the basis for the assessment in the Terrestrial Noise and Vibration Technical Report (Volume 5C) define both an expected existing environment and allowable thresholds for sound levels at homes. The Health Canada guidance also used, either looks at an upper limit or bases the degree of change on existing conditions. The directive and guidelines all take into account the natural fluctuations in outdoor sound.

The perception of change in sound levels for people will depend on the amount of sound that occurs on average over time, rather than moment by moment. People can typically start to notice a change in sound level of 3 dBA (Crocker 2007). The assessment looked at thresholds for noise on day and night average basis given by the guidelines as well as the potential for long-term of average sound level changes of 3 dBA.

Vibration from blasting is experienced as singular events. The airborne and ground-borne vibration can result in a physical sensation if the blast impulse is strong enough. Blasting may be required for some segments of the pipeline construction, and the vibrations from blasts could be noticed by nearby residents if present. However, blast designs for the Project construction also need to consider existing infrastructure, so the blasts will be limited in size and scope.

7.2.6.4 Potential Effects and Mitigation Measures

<u>Effects Considerations</u>

The review of regulatory requirements and the outcome of the ESA Workshops indicate that no indicators, other than those outlined in the AER *Directive 038* and BC OGC N*oise Control Best Practices Guideline* are to be considered in the evaluation of effects on the Acoustic Environment. Both these documents use similar indicators for long-term average sound levels (on a day and night basis).

The potential for Low Frequency Noise (LFN) is a consideration for sound emitted from industrial facilities. Both the AER *Directive 038* and BC OGC *Noise Control Best Practices Guideline* indicate that LFN should be evaluated where data is available at the initial assessment stage and the detailed analysis of

LFN is a requirement when investigating complaints. Equipment sound emissions of sufficient detail to evaluate LFN are typically not available until a later stage of design or construction planning, generally after vendor and contractor selection. Therefore, the potential for LFN based on the theoretical values used in this assessment was studied in the Terrestrial Noise and Vibration Technical Report (Volume 5C). However, the LFN indicator was not carried into the effects assessment since compliance with this indicator is not a primary requirement of the AER or BC OGC, and due to the theoretical nature of the data used in the assessment.

Identified Potential Effects

Potential effects associated with the construction and operations of the proposed pipeline on acoustic environment indicators are listed in Table 7.2.6-2. These interactions are based on the results of the literature review, desktop analysis, modelling, Aboriginal engagement and consultation with landowners, regulatory authorities and other stakeholders (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.2.6-2 was principally developed in accordance with Trans Mountain standards as well as provincial regulatory guidelines including BC MOE (2012a).

TABLE 7.2.6-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON THE ACOUSTIC ENVIRONMENT

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Acoustic Environment Indicator – Sound Levels				
1.1 Changes in sound level during construction	All	LSA	• Adhere to all federal (*i.e.,* Environment Canada, *Motor Vehicle Safety Act*, *Oil and Gas Occupational Safety and Health Regulations*, Health Canada) and provincial (*i.e.,* Directive 038: Noise Control, *BC Noise Control Guideline Best Practices Guideline*, *Worker's Compensation Act*, section 7.2 of the *Occupational Health and Safety Regulations* [BC Reg 296/97 as amended] Section 7.2 [BC Reg. 382/2004, s.1]) guidelines and regulations and legislation for noise management [Section 7.0]. • Noise abatement and construction scheduling will be considered at noise sensitive locations (*i.e.,* neighbouring landowners) and during noise sensitive periods [Section 7.0]. • Schedule intermittent noise producing events to avoid, where feasible, important habitat of wildlife species at risk/sensitive species/livestock during sensitive periods, where feasible [Section 7.0]. • Enforce vehicle speed limits and inform contractor truck drivers and equipment operators that engine retarder braking in urban areas is prohibited [Section 7.0]. • Maintain equipment in good working condition and in accordance with manufacturer guidelines [Section 7.0]. • Maintain noise suppression equipment on all construction machinery and vehicles in good order [Section 7.0]. • Enclose noisy equipment and use baffles, where and when feasible, to limit the transmission of noise beyond the construction site [Section 7.0]. • Use only the size and power of tools necessary limit noise from power tool operations. Locate stationary equipment, such as compressors and generators located away from noise receptors, to the extent feasible, and follow applicable municipal, provincial and federal guidelines [Section 7.0]. • Implement mitigation measures where residences are located within 300 m of the construction right of way or facility site as outlined in the Noise Management Plan [Section 7.0].	• Increase in sound levels during construction period.

TABLE 7.2.6-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Changes in sound level during construction (cont'd)	See above	See above	• Implement mitigation measures where night time activity (*e.g.,* HDD) on the construction right of way or facility site is located within 500 m of residences as outlined in the Noise Management Plan [Section 7.0].	• See above
1.2 Changes in sound level during operation	All	LSA	• Limit helicopter inspections to weekdays only to the extent practical. • Use of off-road vehicles for inspection should be limited to weekdays if feasible. • Maintain equipment in good working condition and in accordance with manufacturer guidelines. • Maintain noise suppression equipment on all construction machinery and vehicles in good order.	• Periodic noise events due to maintenance and inspections.
2. Acoustic Environment Indicator – Vibrations				
2.1 Changes in vibrations during construction	All	RSA	• Implement mitigation measures where residences are located within 300 m of the construction right of way or facility site as outlined in the Noise Management Plan [Section 7.0]. • Noise Management Plan will limit vibrations to acceptable levels.	• Increase in airborne/ground-borne vibrations during blasting aspects of construction period.
2.2 Changes in vibrations during operation	All	RSA	• None required, buried pipeline.	• No residual effects identified.

Notes: 1 LSA = Acoustic Environment LSA; RSA = Acoustic Environment RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.2.6.5 Potential Residual Effects

The potential residual environmental effects on acoustic environment indicators associated with the construction and operations of the pipeline (Table 7.2.6-2) are:

- increase in sound levels during construction;
- periodic noise events due to maintenance and inspections; and
- increase in airborne/ground-borne vibrations during blasting aspects of construction period.

No residual effects associated with changes in vibrations during operations were identified since the pipeline will be buried and largely unaffected by above ground noise sources.

7.2.6.6 Significance Evaluation of Potential Residual Effects

A quantitative assessment of the acoustic environment was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects. The evaluation of significance of each of the potential residual effects for the acoustic environment relies primarily on the magnitude, duration and frequency of the potential change. The general definitions for these criteria are provided in Table 7.1-2. However, magnitude of residual effects requires further definition for the acoustic environment evaluation and is indicator specific. Magnitude for sound level has been defined based on the degree of compliance with provincial and Health Canada guidelines. Magnitude for vibration levels have been defined based on the degree of compliance with the ON MOE blasting guidance NPC-119. The evaluation is also based on the professional judgment of the assessment team. Details on the guidelines and legislation used to establish the magnitude ratings can be found in the Terrestrial Noise and Vibration Technical Report of Volume 5C.

The definitions of magnitude for the L_{eq} in dBA sound level indicator are:

Negligible: Below BC OGC and AER ambient sound level (ASL).

Low: Below BC OGC/AER permissible sound level (PSL) limits and Health Canada limit.

Medium: Less than Health Canada 75 dBA guideline limit for construction but greater than the temporary activity AER/BC OGC daytime PSL of 60 dBA in rural areas to 76 dBA in heavily urbanized areas.

High: Greater than the Health Canada 75 dBA guideline limit for construction.

The definitions of magnitude for the vibration indicators are:

Negligible: No change to ambient vibration levels.

Low: Below ON MOE limits of 120 dBL (airborne) and 10 mm/s (ground-borne).

Medium: Equal to or slightly below ON MOE limits of 120 dBL (airborne) and 50 mm/s (ground-borne).

High: Greater than ON MOE limits of 120 dBL (airborne) and/or 50 mm/s (ground-borne).

Table 7.2.6-3 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the proposed pipeline on the acoustic environment. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.6-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON ACOUSTIC ENVIRONMENT

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Acoustic Environment Indicator – Sound Levels									
1(a) Increase in sound levels during construction period.	Negative	LSA	Short-term	Isolated	Short-term	Low to medium	High	Moderate	Not significant
1(b) Periodic noise events due to maintenance and inspections.	Negative	LSA	Short-term	Periodic	Immediate to short-term	Negligible to medium	High	Moderate	Not significant
1(c) Combined effects on the sound level indicator (1[a] and 1[b].)	Negative	LSA	Short-term	Isolated	Short-term	Low to medium	High	Moderate	Not significant
2. Acoustic Environment Indicator – Vibration									
2(a) Increase in airborne/ground-borne vibrations during blasting aspects of construction period.	Negative	LSA	Short-term	Isolated	Short-term	Low to medium	High	Moderate	Not significant

Notes: 1 LSA = Acoustic Environment LSA; RSA = Acoustic Environment RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Acoustic Environment Indicator – Sound Levels

The following provides the evaluation of significance of potential residual effects on the sound level indicator.

Increase in Sound Levels During Construction Period

The potential for the increase in daytime or night time sound levels for human receptors associated with pipeline construction is considered to have a negative impact balance. Participants of several of the Community Workshops (*e.g.*, Edmonton, Wabamun, Edson, Valemount, Blue River, Clearwater, Kamloops Merritt, Hope, Abbotsford, Langley, Surrey) noted that construction was a concern for local residents and could potentially affect other users in the area (*e.g.*, recreational users in provincial parks, campers, hunters) if construction were to coincide with summer months. The latter concern is further discussed under the human occupancy and resource use element in Volume 5B and in the Socio-Economic Technical Report (Volume 5D). Based on the results of the analysis in the Terrestrial Noise and Vibration Technical Report (Volume 5C), the spatial extent of changes to sound levels from pipeline construction were limited to the Acoustic Environment RSA. However, the significance of changes is based on the compliance with regulatory guidance for noise. Compliance with regulatory requirements occurs within the Acoustic Environment LSA.

The duration of the sounds experienced at receptors is dependent on the activity; each type of sound will last only for the particular phase of construction (*e.g.,* clearing, trenching, welding, and reclamation). As described in Section 2.0, construction is expected to last for approximately 3 months at any location along the propose pipeline corridor. However, within that period, the various phases of construction will occur consecutively. Given the need to transition each phase, the time for maximum activity during each phase is limited. Maximum activity from construction phases may occur within the closest proximity of a particular residential receptor for one to two weeks. In urban areas, activities are expected to be limited to one week.

The frequency of sound emissions during each construction phase will be isolated, as construction is cyclic and involves use of mobile equipment and intermittent use of tools. The period over which the change in noise extends is the construction period and, therefore, the residual effect is conservatively considered to be of short-term reversibility. However, as soon as construction activity stops, the sound level changes are reversed.

The results of predictive modelling for construction of the pipeline indicates the magnitude of changes in sound levels that will be experienced by people living within 1.5 km of the proposed pipeline corridor for a variety of construction activities. Noise controls that will be in use during the construction phase, particularly the use of silencers on mobile equipment and executing a communications plan with receptors are expected to control the amount of sound to within acceptable levels as established in the Terrestrial Noise and Vibration Technical Report of Volume 5C. Controlling the magnitude of sound level changes also limits the spatial extent of the potential change.

A generic model for various types of construction activities was developed, which indicates the maximum expected sound levels from an activity at various distances from that activity on an hourly basis. Given the normal variation in activity during the day for construction, actual sound levels over the full day are expected to be less, although planning for activity cycles is not conducted until later in the Project development process. The maximum hour is being compared to longer term (15 hour day) criteria as an indication of the potential for effect. The summary of results for construction activity is shown in Figure 7.2.6-1.

As shown in Figure 7.2.6-1, the magnitude of effect due to sound from Project construction varies depending on the distance between the construction activities and the surrounding receptors. As such, the evaluation of magnitude has been broken down into each of the applicable five segments of proposed pipeline corridor to allow for consideration of receptors along the length of the corridor.

The types of equipment used and in turn, the sound emissions used for the assessment are similar to those used for construction of other developments such as highways or industrial parks. Day-long sound levels and the degree of variation in sound levels experienced from pipeline construction are expected to be similar to sounds perceived near these types of activities.

<u>Edmonton to Hinton Segment</u>

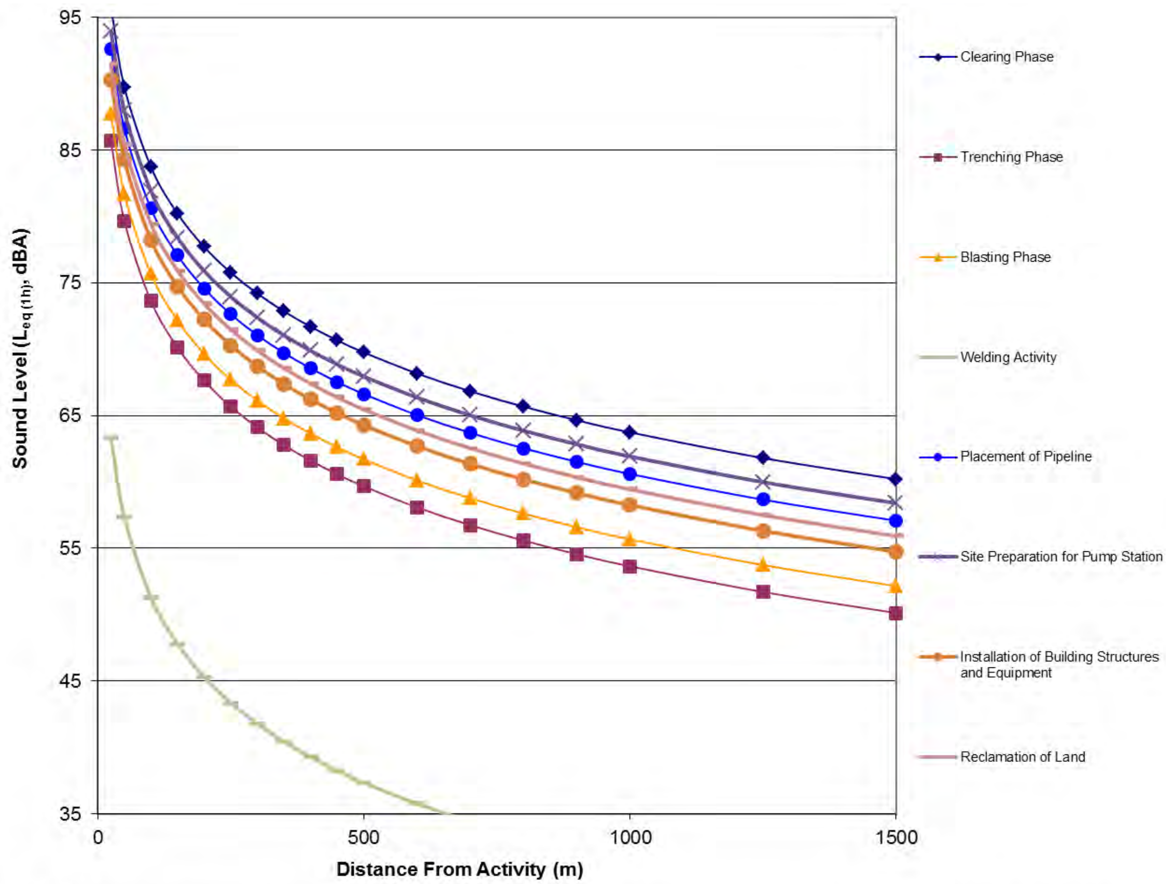
The setback distances from edge of the proposed pipeline corridor to the noise sensitive receptors along the Edmonton to Hinton Segment of the proposed pipeline corridor ranges from close by in urban areas, such as the City Edmonton, Town of Hinton and the Town of Edson, to distant, as far as the boundary of the Acoustic Environment LSA in rural areas. The closest urban receptor to the proposed pipeline corridor was found to be approximately 40 m away in the City of Edmonton near RK 33. The closest rural receptor is immediately adjacent to the pipeline corridor (less than 20 m) located near RK 79. Based on Figure 7.2.6-1, the anticipated sound level at the closest receptor is greater than 85 dBA depending on the activity. The magnitude for this receptor is rated as high. The number of potentially affected receptors at various distances from the proposed pipeline corridor was estimated through review of available mapping and land use data. Estimates rounded to the nearest 50 homes are presented in Table 7.2.6-4. Note that the number of potentially affected receptors is conservative as it is based on available map data. Actual numbers are anticipated to be lower based on a finalized route and receptor ground-truthing.

TABLE 7.2.6-4

DISTANCES TO NOISE SENSITIVE RECEPTORS WITHIN THE ACOUSTIC ENVIRONMENT LSA OF PROPOSED PIPELINE CORRIDOR WITHIN THE EDMONTON TO HINTON SEGMENT

Distance from Proposed Pipeline Corridor (m)	Number of Potentially Affected Receptors (approximate)	Magnitude of Potential Residual Effects
0-300	8,150	High
300-1,500	54,300	Low to medium

Figure 7.2.6-1 Predicted Construction Sound Level Estimates



Notes:
- Predicted noise levels account for distance attenuation (geometric spreading) only. Actual sound levels at distances greater than 300 m would be expected to be much less than those shown.
The quantity and type of each equipment used in each actvity phase is presented in the Terrestrial Noise and Vibration Technical Report (Volume 5C)

While the prediction results indicate there is potential for high magnitude effects at homes within 300 m of the proposed pipeline corridor due to construction noise, these sounds will vary throughout the day, and can be controlled to meet municipal bylaws. The detailed construction planning required to fully assess urban sound levels is not available at this stage of Project planning. However, should specific and localized construction activities necessitate operating on a 24 hour basis to completion, such as horizontal directional drilling of a watercourse, a noise management plan will be prepared in the event human receptors are present within 300 m of the watercourse. In addition, a noise management plan to be prepared for use during construction in urban environments is expected to bring potential sound levels to within levels that result in medium magnitude effects.

Hargreaves to Darfield Segment

The setback distances from the edge of the proposed pipeline corridor to the noise sensitive receptors along the Hargreaves to Darfield Segment of the proposed pipeline corridor range from close, in moderately urbanized areas such Village of Valemount, Community of Blue River, Community of Avola and the Hamlet of Blackpool, to distant, as far as the boundary of the Acoustic Environment LSA in rural areas. The closest identified receptor to the proposed pipeline corridor was found to be adjacent to the corridor (less than 20 m away) near RK 614. Based on Figure 7.2.6-1, the anticipated sound level at the closest receptor is greater than 85 dBA, depending on the type of activity. The magnitude for this receptor is rated as high. The number of potentially affected receptors at various distances from the proposed pipeline corridor was estimated through review of available mapping and land use data. Estimates rounded to the nearest 50 homes are presented in Table 7.2.6-5. Note that the number of potentially affected receptors is conservative as it is based on available map data. Actual numbers are anticipated to be lower based on a finalized route and receptor ground-truthing.

TABLE 7.2.6-5

DISTANCES TO NOISE SENSITIVE RECEPTORS WITHIN THE ACOUSTIC ENVIRONMENT LSA OF PROPOSED PIPELINE CORRIDOR WITHIN THE HARGREAVES TO DARFIELD SEGMENT

Distance from Proposed Pipeline Corridor (m)	Number of Potentially Affected Receptors	Magnitude of Potential Residual Effects
0-300	750	High
300-1,500	2,100	Low to medium

While the prediction results indicate there is potential for high magnitude effects at homes within 300 m of the proposed pipeline corridor due to construction noise, these sounds will vary throughout the day, and can be controlled to meet municipal bylaws. The detailed construction planning required to fully assess urban sound levels is not available at this stage of Project planning. However, should specific and localized construction activities necessitate operating on a 24 hour basis to completion, such as horizontal directional drilling of a watercourse, a noise management plan will be prepared in the event human receptors are present within 300 m of the watercourse. In addition, a noise management plan to be prepared for use during construction in urban environments is expected to bring potential sound levels to within the 75 dBA threshold that results in medium magnitude effects.

Black Pines to Hope Segment

The setback distances from the edge of the proposed pipeline corridor to the noise sensitive receptors along the Black Pines to Hope Segment of the proposed pipeline corridor range from close in urban areas such as the City of Kamloops, City of Merritt and the District of Hope to the boundary of the Acoustic Environment LSA in rural areas. The closest identified receptor to the proposed pipeline corridor was found to be adjacent to the corridor (less than 20 m away) near RK 845. Based on Figure 7.2.6-1, the anticipated sound level at the closest receptor is greater than 85 dBA, depending on the type of activity. The magnitude for this receptor is rated as high. The number of potentially affected receptors at various distances from the proposed pipeline corridor was estimated through review of available mapping and land use data. Estimates rounded to the nearest 50 homes are presented in Table 7.2.6-6. Note that the number of potentially affected receptors is conservative as it is based on available map data. Actual numbers are anticipated to be lower based on a finalized route and receptor ground-truthing.

TABLE 7.2.6-6

DISTANCES TO NOISE SENSITIVE RECEPTORS WITHIN THE ACOUSTIC ENVIRONMENT LSA OF PROPOSED PIPELINE CORRIDOR WITHIN THE BLACK PINES TO HOPE SEGMENT

Distance from Proposed Pipeline Corridor (m)	Number of Potentially Affected Receptors	Magnitude of Potential Residual Effects
0-300	2,300	High
300-1,500	9,450	Low to medium

While the prediction results indicate there is potential for high magnitude effects at homes within 300 m of the proposed pipeline corridor due to construction noise, these sounds will vary throughout the day, and can be controlled to meet municipal by-laws. The detailed construction planning required to fully assess urban sound levels is not available at this stage of Project planning. However, should specific and localized construction activities necessitate operating on a 24 hour basis to completion, such as horizontal directional drilling of a watercourse, a noise management plan will be prepared in the event human receptors are present within 300 m of the watercourse. In addition, a noise management plan to be prepared for use during construction in urban environments is expected to bring potential sound levels to within levels the 75 dBA threshold that results in medium magnitude effects.

Hope to Burnaby Segment

The setback distances from the edge of the proposed pipeline corridor to the noise sensitive receptors along the Hope to Burnaby Segment of the proposed pipeline corridor range from close in urban areas, such as the Township of Langley, the City of Surrey and the City of Burnaby, to distant, as far as the edge of the Acoustic Environment LSA in rural areas. The closest urban receptors to the proposed pipeline corridor were found to be adjacent to the corridor (less than 20 m away) and occur at multiple locations along the proposed pipeline corridor, particularly as the corridor enters urban areas east of Burnaby. Based on Figure 7.2.6-1, the anticipated sound level at the closest receptors is greater than 85 dBA, depending on the type of activity. The magnitude for this receptor is rated as high. The number of potentially affected receptors at various distances from the proposed pipeline corridor was estimated through review of available mapping and land use data. Estimates rounded to the nearest 50 homes are presented in Table 7.2.6-7. Note that the number of potentially affected receptors is conservative and actual numbers are anticipated to be lower based on a finalized route.

TABLE 7.2.6-7

DISTANCES TO NOISE SENSITIVE RECEPTORS WITHIN THE ACOUSTIC ENVIRONMENT LSA OF PROPOSED PIPELINE CORRIDOR WITHIN THE HOPE TO BURNABY SEGMENT

Distance from Proposed Pipeline Corridor (m)	Number of Potentially Affected Receptors	Magnitude of Potential Residual Effects
0-300	14,00	High
300-1,500	57,100	Low to medium

While the prediction results indicate there is potential for high magnitude effects at receptors within 300 m of the proposed pipeline corridor due to construction noise, these sounds will vary throughout the day, and can be controlled through detailed planning and use of sound reduced equipment in densely populated areas. The detailed construction planning required to fully assess urban sound levels is not available at this stage of project planning. A detailed noise management plan to be prepared for use during construction in urban environments is expected to bring potential sound levels to within the 75 dBA threshold that results in medium magnitude levels.

Burnaby to Westridge Segment

The setback distances from the edge of the proposed pipeline corridor to the noise sensitive receptors along the Burnaby to Westridge Segment of proposed pipeline corridor are considered short due to the degree of urbanization along this segment of the proposed pipeline corridor. The closest identified receptors to the proposed pipeline corridor were found to be adjacent to the corridor (less than 20 m away) and were locations along the final 1.5 km of the pipeline. Based on Figure 7.2.6-1, the anticipated sound level at the closest receptor is greater than 85 dBA, depending on the type of activity. The magnitude for this receptor is rated as high. The number of potentially affected receptors at various distances from the proposed pipeline corridor was estimated through review of available mapping and land use data. Estimates rounded to the nearest 50 homes are presented in Table 7.2.6-8. Note that the number of potentially affected receptors is conservative as it is based on available map data. Actual numbers are anticipated to be lower based on a finalized route and receptor ground-truthing.

TABLE 7.2.6-8

DISTANCES TO NOISE SENSITIVE RECEPTORS WITHIN THE ACOUSTIC ENVIRONMENT LSA OF PROPOSED PIPELINE CORRIDOR WITHIN THE BURNABY TO WESTRIDGE SEGMENT

Distance from Proposed Pipeline Corridor (m)	Number of Potentially Affected Receptors	Magnitude of Potential Residual Effects
0-300	1,376	High
300-1,500	6,950	Low to medium

While the prediction results indicate there is potential for high magnitude effects at receptors within 300 m of the proposed pipeline corridor due to construction noise, these sounds will vary throughout the day, and can be controlled through detailed planning and use of a noise management plan. The detailed construction planning required to fully assess urban sound levels is not available at this stage of project planning. A detailed noise management plan to be prepared for use during construction in urban environments is expected to bring potential sound levels to within medium magnitude levels.

Residential dwellings are located within sufficient proximity of construction activity for sound level changes to occur along much of the proposed pipeline corridor. Therefore, the probability of occurrence is high.

The predictive modelling used in the assessment of the acoustic environment has a level of uncertainty that is dependent on three factors: the accuracy of the sound source data; the precision of the noise propagation model; and the accuracy of locations and quantities of noise sources. Conservative choices were made regarding the sound source data. Where practical, measured data of similar equipment were used but often theoretical data was required which increases uncertainty in the results. A model that uses key international standards for outdoor sound propagation with a known uncertainty was used and the locations and quantities of sources are based on Section 2.0 of Volume 5A. The confidence that the results are conservative, yet representative is considered moderate.

A summary of the rationale for all of the significance criteria is provided below (Table 7.2.6-3, point 1[a]).

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER *Directive 038* and BC OGC *Noise Control Best Practices Guideline* are achieved within the Acoustic Environment LSA.
- Duration: short-term – the events causing changes in sound levels occur only during the construction phase.
- Frequency: isolated – the events causing changes in sound level occur at residential dwellings occur during the construction phase.
- Reversibility: short-term – the period over which the change in sound level extends is the construction period. However, at any specific location along the proposed pipeline corridor, all sound level changes will cease when construction activities have finished.
- Magnitude: low to medium – in urban areas, with the implementation of a detailed noise management plan for construction, the changes in sound level are considered to be medium while in rural areas, the change in sound level ranges from low to medium depending on the distance from construction activity.

- Probability: high – based on the proximity of residences to the proposed pipeline corridor.
- Confidence: moderate – based on the nature of data inputs.

Periodic Noise Events Due to Maintenance and Inspections

Noise from pipeline operations is limited to regular aerial and ground patrols vegetation management and integrity digs. Sounds would be similar to those already heard in areas where the proposed pipeline corridor is adjacent to the existing TMPL right-of-way. Similar to noise during construction, noise resulting from periodic site-specific maintenance will be limited to the same receptors in close proximity to the proposed pipeline corridor.

The spatial extent of the change sound level is limited to the Acoustic Environment LSA. Since maintenance activities are typically completed at any given location within a few minutes to hours (aerial patrols, vegetation management) or within several weeks (*e.g.*, integrity digs), the duration of the maintenance and inspection activities is short-term. The frequency of maintenance activities occur intermittently but repeatedly over the assessment period and, therefore, are considered to be periodic. The effect is reversible in the immediate to short-term as sound level changes due to maintenance activity will cease as soon as the maintenance activity stops.

While aerial patrols or vegetation management during operations may cause momentary sound levels to increase, the day and night average levels are not expected to change due to such short duration events. Although integrity digs may extend over several weeks, the amount and size of the equipment used during this activity is generally smaller than that used during pipeline construction. Nevertheless, the magnitude of the change in sound level during operations of the pipeline is considered to be of negligible magnitude for most operational activities and of medium magnitude for integrity digs where there are nearby human receptors.

The inspections and maintenance are essential to safe pipeline operations so the probability of occurrence is rated as high. The confidence is considered moderate based on the uncertainty in the data used for the evaluation of fly-by noise. A summary of the rationale for all of the significance criteria is provided below (Table 7.2.6-3, point 1[b]).

- Spatial Boundary: Acoustic Environment LSA – the change in sound level during operations is confined to the Acoustic Environment LSA.
- Duration: short-term – the events causing changes in sound levels during operations (*i.e.*, maintenance activities) are completed within any 1 year during operations.
- Frequency: periodic – the events causing changes in sound levels during operations (*i.e.*, aerial patrols, vegetation management, integrity digs) occur intermittently but repeatedly over the assessment period.
- Reversibility: immediate to short-term – the changes in sound level associated with maintenance activities at any given location range from a few minutes to hours for aerial patrols and vegetation management (immediate) to a few weeks for integrity digs (short-term). All sound level changes are reversible as the sound will cease when the inspection/maintenance is finished.
- Magnitude: negligible to medium – the sound level events associated with aerial patrols and vegetation management will have a short timeline, so changes to the day or night average levels are not expected. However, integrity digs that occur near residents may result in sound level changes that could affect day or night average levels.
- Probability: high – changes to sound levels will occur since inspections and maintenance are essential to safe pipeline operation.
- Confidence: moderate – based on the uncertainty in the data used for the evaluation of fly-by noise.

Combined Effects on Sound Levels

The evaluation of the combined effects of pipeline construction and operations on the acoustic environment considers collectively the assessment of the likely potential residual effects on the sound levels indicator. The residual effects for changes in sound level do not combine between the two elements to result in new ratings. Both effects are different types of sounds as well as time periods for occurrence; they do not combine into a singular effect. Therefore, the combined effects on sound levels in Table 7.2.6-3 point 1(c) represents the worst-case or most adverse effect for each evaluation criteria between the two residual effects. Effectively, this reflects effects from pipeline construction, as pipeline operations have comparatively lower sound generating activity.

A summary of the rationale for all of the significance criteria of combined effects on sound levels is provided below.

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER *Directive 038* and BC OGC *Noise Control Best Practices Guideline* are achieved within the Acoustic Environment LSA.
- Duration: short-term – the events causing combined effects on sound level occur only during the construction phase.
- Frequency: isolated – the events causing combined effects on sound level will occur at residential dwellings during the construction phase
- Reversibility: short-term – the period over which the combined effects on sound levels extend is the construction period. However, at any specific location along the proposed pipeline corridor, all sound level changes will cease when construction activities have finished.
- Magnitude: low to medium – in urban areas, with the implementation of a detailed noise management plan for construction, the combined effects on sound level are considered to be medium while in rural areas, the combined effects on sound level ranges from low to medium depending on the distance from construction activity.
- Probability: high – combined effects on sound level is likely to occur based on the proximity of residences to the proposed pipeline corridor.
- Confidence: moderate – based on the nature of data inputs.

Acoustic Environment Indicator – Vibration Levels

The following provides details on the significance of the potential residual effects that are present in the acoustic environment due to vibration levels cause by the blasting activities of the proposed pipeline construction component of the Project.

Increase in Airborne/Ground-Borne Vibrations During Blasting Aspects of Construction Period

The potential for the increase in vibration (airborne and ground-borne) levels for human receptors associated with increased Project construction is considered to have a negative impact balance. Based on the results of the analysis in the Terrestrial Noise and Vibration Technical Report of Volume 5C, the spatial extent of changes to vibration levels from pipeline construction are limited to a blast design specification of 50 mm/sec peak particle velocity (PPV) at the nearest structure or infrastructure within or near the proposed pipeline corridor. This is usually the existing pipe at a minimum 5 m distance. Blast size is modified to ensure the 50 mm/s requirement is met. Where the 50 mm/s requirement is met, the airborne component of the vibration meets 120 dB at 50 m distance. This results in medium magnitude effects. The duration of the vibration levels experienced at receptors is very short (dependent on size and formation of blasting pattern). The frequency of vibration emissions during construction will be limited, since it should only be used in areas that are needed and where ripping is not feasible (heavy equipment limitations, bedrock). All changes in vibration levels are immediately reversible. As soon as blasting construction activity stops, the vibration level changes are reversed.

Vibration controls that will be in use during the construction phase, limit blasting to daytime hours, vary shape and charge with respect to proximity to local receptors and executing a communications plan with receptors are expected to limit vibration levels to within acceptable levels as established in the Terrestrial Noise and Vibration Technical Report. Controlling the magnitude of vibration level also limits the spatial extent of the potential change.

The only variation in residual effects along the pipeline corridor is the magnitude of potential effects. The magnitude of the effect will vary depending on the distance between the blasting zone and the surrounding receptors. As the exact blasting zones have not been determined, the closest potential rural receptor in each segment has been used for evaluation. Blasting will not occur in urbanized areas. This resulted in the most conservative estimates for the highest magnitude of potential effects. A summary of potential magnitude of effects from vibration is provided in Table 7.2.6-9. The analysis lists each of the five segments along with both the estimated distance to receptor and the resulting magnitude of potential effects. As presented in Table 7.2.6-9, the magnitude of residual effect from vibration is medium for all segments of the proposed pipeline corridor.

TABLE 7.2.6-9

SUMMARY OF DISTANCES TO NOISE SENSITIVE RECEPTORS WITHIN EACH SEGMENT OF THE PROPOSED PIPELINE CORRIDOR

Pipeline Segment	Distance from Proposed Pipeline Corridor (m)	Magnitude of Potential Residual Effects
Edmonton to Hinton	<20	Medium
Hargreaves to Darfield	<20	Medium
Black Pines to Hope	<20	Medium
Hope to Burnaby	<20	Medium
Burnaby to Westridge	N/A (no rural receptors)	N/A (no rural receptors)

Residences are within sufficient proximity of construction activity for vibration level changes to occur along most of the proposed pipeline corridor. Therefore, the probability of occurrence is high.

The predictive modelling used in the assessment of the acoustic environment has a level of uncertainty that is dependent on three main factors: the blasting source data; the precision of the vibration propagation model; and the accuracy of locations of blasting locations. Blasting configuration and design data were not available at this stage of the Project. The blasting limit for effects on the existing pipeline corridor was used to estimate vibration levels at each representative receptor along each segment of proposed pipeline corridor. Modelling was completed that uses key international standards for outdoor vibration propagation with a known uncertainty. Therefore, the confidence in the results was considered moderate.

A summary of the rationale for all of the significance criteria is provided below (Table 7.2.6-3, point 2[a]).

- Spatial Boundary: Acoustic Environment LSA – effects associated with changes to vibration level extend to less than 100 m from the right-of-way in most areas, but are dependent on the location of the activity. In an area that is greenfield with no existing rights-of-way, or where receptors are more distant, higher charge weights may be used. The type of blasting required for a pipeline uses smaller charges. Charge weights sufficient for vibrations to reach 1,500 m (the edge of the LSA) would be greater than 1,000 kg which would not occur for this Project.
- Duration: short-term – the changes to vibration levels occur only during the construction phase.
- Frequency: isolated – the event causing changes to vibration levels occur only during the construction phase in which the activity is planned.
- Reversibility: short-term – the changes to vibration levels are associated with blasting activities which may occur over a period longer than two days. All vibration level changes are reversible as the vibration will cease when construction is finished.

- Magnitude: low to medium – based on the anticipated effects at receptors, PPV at residences is expected to be less than the 50 mm/s design specification due to the blasting limit for the existing pipeline corridor.
- Probability: high – based on the proximity of receptors to the proposed pipeline corridor.
- Confidence: moderate – based on the nature of data inputs.

7.2.6.7 Summary

As identified in Table 7.2.6-3, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the acoustic environment indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline construction and operations on the acoustic environment will be not significant.

7.2.7 Fish and Fish Habitat

This subsection describes the potential Project effects on fish and fish habitat. The Fisheries (Alberta) Technical Report and Fisheries (British Columbia) Technical Report of Volume 5C provide further information pertaining to fish and fish habitat at watercourses affected by the Project.

Pipeline construction and maintenance activities have the potential to directly and indirectly affect fish and fish habitat through riparian and instream habitat contamination, loss or alteration of riparian and instream habitat during construction and maintenance, contamination of instream or riparian habitat from spills and increase the risk of contamination through accidental drilling mud release during construction.

Fish mortality or injury may increase during construction due to an increase in suspended sediment concentration, increased site access, blockage of fish movements and effects on fish species of concern. Pipeline construction and maintenance may also result in combined effects on each indicator species resulting from contamination, loss or alteration of riparian or instream habitat and mortality or injury.

The assessment of effects on fish and fish habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks and pipeline reactivation), since potential effects related to riparian habitat, instream habitat and fish mortality and injury are experienced in a combined manner on fish indicator species and cannot be meaningfully disaggregated by Project component. Construction of the Westridge Marine Terminal will not cause any interactions with fish and fish habitat.

7.2.7.1 Assessment Indicators and Measurement Endpoints

Assessment indicators identified for the fish and fish habitat element are: riparian habitat (Alberta and BC); instream habitat (Alberta and BC); fish mortality or injury (Alberta and BC); Arctic grayling (Alberta); Athabasca rainbow trout (Alberta); bull trout (Alberta); burbot (Alberta); northern pike (Alberta); walleye (Alberta); bull trout/Dolly Varden (BC); Chinook salmon (BC); coho salmon (BC); cutthroat trout (BC); and rainbow trout/steelhead (BC). Assessment indicators and measurement endpoints for fish and fish habitat are listed in Table 7.2.7-1. Potential effects related to the fish and fish habitat are considered under Section 7.2.7.4.

The selection of indicators for fish and fish habitat included; consideration of the filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues; feedback from Aboriginal communities, regulatory authorities and stakeholders; feedback from ESA Workshops; available research literature; public issues raised through media; and the professional judgment of the assessment team.

It was determined by the assessment team that each province traversed by the proposed pipeline corridor (*i.e.*, Alberta and BC) should have its own set of fish species indicators. This is due to a variety of factors, including regional differences in fish community compositions, species abundance, and species important for recreational, commercial or traditional use. Three general fish and fish habitat indicators (*i.e.*, riparian habitat, instream habitat and fish mortality and injury) were determined to be appropriate for both provinces and for all project components. The indicator species in Alberta are Arctic grayling, Athabasca rainbow trout, bull trout, burbot, northern pike and walleye. The BC fish indicator species are bull trout/Dolly Varden, Chinook salmon, coho salmon, cutthroat trout and rainbow trout/steelhead. Table 7.2.7-1 provides the rationale for the selection of each indicator species.

The determination of fish and fish habitat indicator species for each province considered sportfish species, species of management concern and species of conservation concern. Species in each province were selected due to their presence throughout the Aquatics RSA and because they are known to be found in many of the watercourses crossed by the proposed pipeline corridor. Although additional species at risk (listed federally and/or provincially) are found in watercourses crossed by the proposed pipeline corridor, not every species at risk is considered to be an appropriate indicator since some of these species have limited range within the Aquatics RSA.

Federally and provincially listed species found in Project watersheds in Alberta include lake sturgeon, sauger, spoonhead sculpin and northern redbelly dace (Section 4.4 in the Fisheries [Alberta] Technical Report of Volume 5C). Fish species of conservation concern found in Project watersheds in BC include Salish sucker, nooksack dace, green sturgeon, white sturgeon, mountain sucker, coastrange sculpin, western brook lamprey, eulachon, chiselmouth and sockeye salmon (Sections 4.4 and 4.5 in the Fisheries [British Columbia] Technical Report of Volume 5C). Other species of management concern are described in Section 4.5 of the Fisheries (Alberta) and Section 4.6 of the Fisheries (British Columbia) Technical Report of Volume 5C and include several exotic (*i.e.,* non-native) species and sportfish species

Although these listed species were not selected as indicators in this assessment, they will be used as indicators in the watercourses in which they are found. The mitigation measures at a given watercourse are expected to also be effective at reducing potential effects to these species (Section 7.0 of the Fisheries [Alberta] and Fisheries [British Columbia] Technical Reports of Volume 5C). Scientific names corresponding to the common fish species names used in this document can be found in the Fisheries [Alberta] and Fisheries [British Columbia] Technical Reports of Volume 5C.

The proposed indicators for fish and fish habitat were discussed during the Edmonton, Kamloops and Surrey ESA Workshops. There was general consensus by the participants at the workshops that the proposed fish and fish habitat indicators were appropriate for evaluating the effects of the Project on fish and fish habitat. The addition of burbot as an Alberta indicator species was suggested by representatives from AESRD at the Edmonton ESA Workshop since it is being more frequently targeted by anglers throughout the Aquatics RSA. Upon consideration by the assessment team, burbot was adopted as an indicator species in Alberta given the rationale proposed by AESRD, as well as because burbot spawns in the winter, which is unique among the Alberta indicator species. In addition, burbot is found throughout the Aquatics RSA in Alberta.

Lake sturgeon was suggested as an Alberta indicator species by participants at the Edmonton ESA Workshop. Lake sturgeon in Alberta is listed as Threatened under the Alberta *Wildlife Act* and *Wildlife Regulation* and Endangered under the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) (2006a, 2013). Although lake sturgeon was considered as an indicator species in Alberta, it was decided that lake sturgeon is not an appropriate indicator since it has a limited distribution in the Project watersheds and is only found in one watercourse (*i.e.*, North Saskatchewan River) crossed by the proposed pipeline corridor. Therefore, potential effects to lake sturgeon would not be representative of overall effects to fish and fish habitat.

The Fraser Valley Regional District suggested the use of Nooksack dace as an indicator species in BC. Nooksack dace is Endangered under COSEWIC (2013) and Schedule 1 of *SARA* (Environment Canada 2013c) and has a very limited distribution in BC. Historical data and the results of the field program (see Section 4.4.4 of the Fisheries [British Columbia] Technical Report of Volume 5C) indicate that Nooksack dace is only found in two watercourses (*i.e.*, Salmon River, Stoney Creek) crossed by the proposed pipeline corridor. Since Nooksack dace has a limited distribution in watercourses crossed by the proposed pipeline corridor, it was determined that this species would not be useful as an indicator species since potential effects to Nooksack dace would not be representative of potential effects to all fish and fish habitat.

Sockeye salmon was suggested as a BC indicator by participants at the Surrey ESA Workshop. Sockeye is Endangered under COSEWIC (2013). Sockeye are not as well distributed throughout the Project area as Chinook or coho salmon, therefore, sockeye salmon would not be representative of potential effects to overall fish and fish habitat.

The use of benthic invertebrates as an indicator was considered and it was determined that they are not appropriate as an indicator for pipeline projects as discussed in Section 7.2.7.4.

The measurement endpoints for the selected indicators include both quantitative and qualitative measurements of potential Project effects. Table 7.2.7-1 provides a summary of the indicators and measurement endpoints used in the assessment of potential effects on fish and fish habitat.

TABLE 7.2.7-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR FISH AND FISH HABITAT

Fish and Fish Habitat Indicators	Measurement Endpoints	Rationale for Indicator Selection
Riparian habitat (Alberta and BC)	• Overall area of riparian habitat (m^2) altered along watercourses and non-classified drainages (NCDs) crossed by the proposed pipeline corridor.	• Area of riparian habitat disturbance can be used as an indicator of overall watershed health (Salmo *et al.* 2003, Sawyer and Mayhood 1988, Scrimgeour *et al*. 2003). • Disturbances in riparian areas can contribute to increased sediment yields (*e.g*., Anderson 1998, Beaudry 1998) and affect fish community assemblages (*e.g.*, Haas 2001, Sloat *et al*. 2001). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to describe "sensitive areas and sensitive habitats, including wetlands and riparian habitat".
Instream habitat (Alberta and BC)	• Overall area of instream habitat (m^2) altered in watercourses and NCDs crossed by the proposed pipeline corridor.	• Valuable for sport, commercial and subsistence fisheries.
Fish mortality or injury (Alberta and BC)	• Mortality or Injury to fish during construction	• Will be used as a qualitative indicator of potential effects on fishes (e.g., damage to gill tissue, physiological stress, growth reduction and mortality) (Kerr 1995, Newcombe and MacDonald 1991).
Arctic grayling (Alberta)	• Qualitative assessment of changes to Arctic grayling riparian habitat, instream habitat and injury or mortality to Arctic grayling.	• Geographically distributed throughout four Project watersheds in Alberta (Table 5.7-14 in Section 5.7.6). • A general status of Sensitive (ASRD 2010) and considered a Species of Special Concern by the Alberta Endangered Species Conservation Committee (ESCC) (AESRD 2012a). A management and recovery plan has been implemented (Berry 1998). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area".
Athabasca rainbow trout (Alberta)	• Qualitative assessment of changes to Athabasca rainbow trout riparian habitat, instream habitat and injury or mortality to Athabasca rainbow trout.	• Geographically distributed throughout three Project watersheds in Alberta (Table 5.7-14 in Section 5.7.6). • A general status of At Risk (ASRD 2010); although Athabasca rainbow trout are not a distinct subspecies, COSEWIC guidelines recognize Athabasca rainbow trout populations as a "designatable unit" below the species level (ASRD and Alberta Conservation Association [ACA] 2009). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area".
Bull trout (Alberta)	• Qualitative assessment of changes to bull trout riparian habitat, instream habitat and injury or mortality to bull trout.	• Geographically distributed throughout four Project watersheds in Alberta (Table 5.7-14 in Section 5.7.6). • Bull trout – listed under COSEWIC as Threatened and Species of Special Concern (population dependent) (COSEWIC 2013) and as a Species of Special Concern under the Alberta *Wildlife Act* and *Wildlife Regulation* (AESRD 2012a). This species also has a general status of Sensitive (ASRD 2010). A management and recovery plan has been implemented (ASRD 2012, Berry 1994). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area".

TABLE 7.2.7-1 Cont'd

Fish and Fish Habitat Indicators	Measurement Endpoints	Rationale for Indicator Selection
Burbot (Alberta)	• Qualitative assessment of changes to burbot riparian habitat, instream habitat and injury or mortality to burbot.	• Geographically distributed throughout eight Project watersheds in Alberta (Table 5.7-14 in Section 5.7.6). • Burbot – sportfish species (Government of Alberta 2013d) and suggested by AESRD participants at the Edmonton ESA Workshop to be included as an indicator species. • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area".
Northern pike (Alberta)	• Qualitative assessment of changes to northern pike riparian habitat, instream habitat and injury or mortality to northern pike.	• Geographically distributed throughout eight Project watersheds in Alberta (Table 5.7-14 in Section 5.7.6). • Northern pike – a sportfish species (Government of Alberta 2013d) and a management and recovery plan is in place (Berry 1999). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area".
Walleye (Alberta)	• Qualitative assessment of changes to walleye riparian habitat, instream habitat and injury or mortality to walleye.	• Geographically distributed throughout six Project watersheds in Alberta (Table 5.7-14 in Section 5.7.6). • Walleye – sportfish species (Government of Alberta 2013d) and a management and recovery plan is in place (Berry 1995). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area".
Bull trout/Dolly Varden (BC)	• Qualitative assessment of changes to bull trout/Dolly Varden riparian habitat, instream habitat and injury or mortality to bull trout/Dolly Varden.	• Geographically distributed throughout 10 Project watersheds in BC (Table 5.7-15 in Section 5.7.6). • Bull trout and Dolly Varden are both sportfish species (BC MFLNRO 2013a) and bull trout is Blue-listed (BC CDC 2013) provincially and also a Species of Special Concern under COSEWIC (2013). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area". • These two species were combined due to overlapping species distributions in Coast Mountain drainages which makes each species difficult to differentiate except for morphological differences (*i.e.,* head shape, upper jaw length, anal fin base) (Fisheries [British Columbia] Technical Report Section 4.3.4 of Volume 5C, McPhail 2007).
Chinook salmon (BC)	• Qualitative assessment of changes to Chinook salmon riparian habitat, instream habitat and injury or mortality to Chinook salmon.	• Geographically distributed throughout 10 Project watersheds in BC (Table 5.7-15 in Section 5.7.6). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area". • Chinook salmon – sportfish species (BC MFLNRO 2013a), Okanagan population listed under COSEWIC as Threatened (COSEWIC 2013).
Coho salmon (BC)	• Qualitative assessment of changes to coho salmon riparian habitat, instream habitat and injury or mortality to coho salmon.	• Geographically distributed throughout 11 Project watersheds in BC (Table 5.7-15 in Section 5.7.6). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area". • Coho salmon – sportfish species (BC MFLNRO 2013a) and widely distributed. Interior Fraser River population listed by COSEWIC as Endangered (COSEWIC 2013).
Cutthroat trout (BC)	• Qualitative assessment of changes to cutthroat trout riparian habitat, instream habitat and injury or mortality to cutthroat trout.	• Geographically distributed throughout five Project watersheds in BC (Table 5.7-15 in Section 5.7.6). • Cutthroat trout (coastal and westslope) – westslope subspecies provincially listed as a Species of Special Concern (COSEWIC 2013); Coastal cutthroat is Blue-listed provincially (BC MOE 2013b). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area".

TABLE 7.2.7-1 Cont'd

Fish and Fish Habitat Indicators	Measurement Endpoints	Rationale for Indicator Selection
Rainbow trout/steelhead (BC)	• Qualitative assessment of changes to rainbow trout/steelhead riparian habitat, instream habitat and injury or mortality to rainbow trout/steelhead.	• Geographically distributed throughout 13 Project watersheds in BC (Table 5.7-15 in Section 5.7.6). • Rainbow trout/steelhead trout – sportfish species (BC MFLNRO 2013a). • Meets NEB *Filing Manual* requirements for the fish and fish habitat element in Table A-2 to "identify fish species and life stages of ecological, economic or human importance in the study area". • Rainbow trout is a salmonid species that may occur both as a freshwater resident and anadromous (steelhead) population (*i.e.*, rainbow trout and steelhead are the same species).

7.2.7.2 Spatial Boundaries

The spatial boundaries used in the effects assessment of fish and fish habitat considered one or more of the follow areas:

- a Footprint Study Area (as defined in Section 7.1.3);
- a Fish and Fish Habitat LSA; and
- an Aquatics RSA.

The Fish and Fish Habitat LSA is defined as the zone of influence (ZOI) likely to be affected by direct disturbance and sediment deposition during construction and operations, consisting of the area extending 100 m upstream of the centre of the proposed pipeline corridor to a minimum of 300 m downstream of the centre of the proposed pipeline corridor at defined watercourses (BC MOE 2001). The Fish and Fish Habitat LSA also includes the area of riparian vegetation to a width of 30 m back from each bank edge within the width of the construction right-of-way.

Each watercourse crossed by the proposed pipeline corridor has an individually determined downstream LSA based on the ZOI. The ZOI was determined for each crossing in the field based on the professional experience and judgment of the QAES in Alberta or the QEP in BC, who took into account a variety of factors (*e.g.,* stream gradient, channel width, channel depth, substrate composition, channel morphology, flow velocity and discharge and instream cover). The ZOI is typically the reach of a watercourse where 90% of the sediment load caused by construction activities is expected to fall out of suspension (Government of Alberta 2013b,c). At some watercourses the study extent was extended beyond the proposed pipeline corridor in both directions to accommodate for any minor changes to crossing location that may be required. Due to the number of proposed watercourse crossings and differences in the downstream length of the Fish and Fish Habitat LSA based on the estimated ZOI, it was not feasible to map the Fish and Fish Habitat LSA for each individual crossing location. Figures 7.2.7-1 and 7.2.7-2 provide examples of the Fish and Fish Habitat LSA at Zeb-Igler Creek and the Fraser River.

The Aquatics RSA is defined as the area where the direct and indirect influence of other land uses and activities could overlap with Project-specific effects and cause cumulative effects on the fish and fish habitat indicators and includes all watersheds (see Section 5.7) directly affected by the Project. This Aquatics RSA was also considered appropriate due to the recognized presence of several migratory fish species (*e.g.,* Chinook salmon, coho salmon and bull trout) in the vicinity of the Project. The migratory nature of these and other fish species may result in Project-related activities affecting fish populations beyond the Fish and Fish Habitat LSA, but within the Aquatics RSA. The Aquatics RSA is shown in Figures 5.3-1 and 5.3-2.

7.2.7.3 Ecological Context

The proposed Project lies within four drainage basins including the North Saskatchewan and Athabasca river basins in Alberta and the Fraser and Columbia river basins in BC. Twenty-one Project watersheds are crossed by the proposed pipeline corridor as described in Section 4.1 of the Fisheries (Alberta) and Fisheries (British Columbia) Technical Reports of Volume 5C.

Potential watercourse crossings along the proposed pipeline corridor were originally identified during helicopter overflights and from desktop analysis. The 2012 and 2013 fisheries field program investigated 928 potential watercourses crossed by the proposed pipeline corridor (including 10 watercourses that were assessed based on historical information). Ongoing fisheries field studies are discussed in Section 9.0. It was determined that 88 defined watercourses are crossed by the proposed pipeline corridor in Alberta and 386 in BC. Named rivers crossed by the proposed pipeline corridor in Alberta include the North Saskatchewan, Pembina, and McLeod rivers. The proposed pipeline corridor crosses 14 named rivers in BC, including the Fraser and North Thompson rivers. The construction of temporary facilities may require access roads and temporary vehicle crossings, though the location of the facilities and roads has not yet been determined. Hydrostatic testing will be required for the Hinton to Hargreaves and Darfield to Black Pines reactivated segments (in the Athabasca and Fraser river basins, respectively) and the Edmonton, Sumas and Burnaby Terminals (Lower North Saskatchewan, Chilliwack and Lower Fraser river watersheds, respectively).

The Black Pines Pump Station is located in the Lower North Thompson River Watershed. The Kingsvale Pump Station is located in the Lower Nicola River Watershed, although the associated power line extends into the Similkameen River Watershed. The power lines associated with these pump stations cross seven defined watercourses, including the North Thompson River.

7.2.7.4 Potential Effects and Mitigation Measures

Effects Considerations

The effects to benthic invertebrates and the use of benthic invertebrates as an environmental indicator of overall stream health were discussed at the Edmonton, Kamloops and Surrey ESA Workshops. Benthic invertebrates were also suggested as an indicator for surface water quality (Section 7.2.3.4). Although invertebrates are an excellent indicator of overall stream health, they are not a good indicator of disturbance or potential effects of pipeline construction on fish habitat (Newcombe 1994, Reid and Anderson 1999, Tsui and McCart 1981, Wood and Armitage 1997, Young and Mackie 1991).

Newcombe's work on sediment dose-response relationships (Newcombe 1994) identified that effects to benthic invertebrates are directly related to concentration and duration of TSS in a watercourse. Previous studies on pipeline watercourse crossings (*e.g.,* Reid and Anderson 1999, Reid *et al.* 2002, Tsui and McCart 1981, Wood and Armitage 1997, Young and Mackie 1991) showed that benthic invertebrate populations are normally able to withstand short-term increases in suspended sediment and recover quickly following open cut crossings. Therefore, it was determined by the assessment team that this potential effect on benthic invertebrates would not be carried through the assessment.

Identified Potential Effects

Potential effects associated with the construction and operations of the proposed Project on fish and fish habitat indicators are listed in Table 7.2.7-2. These interactions are based on the results of the literature review, desktop analysis, field work, TEK, Aboriginal engagement and consultation with landowners, regulatory authorities and stakeholders (Section 3.0), and the professional experience of the assessment team.

TEK participants identified concerns related to the potential effects of Project construction activities on fish and fish habitat and riparian habitats along the Edmonton to Hinton Segment. Along the Hope the Burnaby Segment, TEK participants have requested that community monitors be on-site during watercourse crossing construction and, in particular, at fish-bearing watercourses. Additional issues and concerns related to fish and fish habitat identified by participating Aboriginal communities through the biophysical field studies for the Project are described in the Fisheries (Alberta) and Fisheries (British Columbia) Technical Reports of Volume 5C. A comprehensive review of the issues raised by participating Aboriginal communities was conducted with each community during the field surveys (Section 3.6.7 of the Fisheries [Alberta] Technical Report and Section 3.2.10 of the Fisheries [British Columbia] Technical Report of Volume 5C).

Appropriate watercourse crossing methods have been selected in consideration of the size, environmental sensitivities of the watercourse (inclusive of TEK) and period of construction (Appendix A of the Fisheries [Alberta] and Fisheries [British Columbia] Technical Reports of Volume 5C). A summary of mitigation measures provided in Table 7.2.7-2 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines including BC MWLAP (2004a), CAPP (2004), CAPP *et al.* (2005), DFO (1995, 2008a,b) and Government of Alberta (2010a, 2013b,c). TEK participants have not recommended any additional mitigation strategies than those described in Table 7.2.7-2 to be implemented for the Project.

TABLE 7.2.7-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON FISH AND FISH HABITAT

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Fish and Fish Habitat Indicator – Riparian Habitat				
1.1 Riparian habitat loss or alteration during construction and maintenance activities	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Access roads Black Pines Pump Station Power line Kingsvale Pump Station Power line	Footprint	• Mark acquired additional temporary workspace (TWS) prior to the initiation of instream work. Ensure additional TWS does not encroach within vegetated riparian buffers [Section 8.7]. • Ensure power line poles or towers are sited outside of the channel width and/or riparian buffer areas of watercourses/wetlands/lakes [Section 11.1]. • See similar measures in Section 11.0 of the Facilities EPP. Vehicle Crossings • Install, use and remove bridges in accordance with the measures identified in the DFO *Operational Statement for Clear-Span Bridges* and *Operational Statement for Bridge Maintenance* [Section 8.7]. Clearing and Grading • Prohibit clearing of extra TWS within the riparian buffer, only the trench and TWS areas will be cleared [Section 8.1]. • Clear vegetation located within the watercourse/wetland/lake vegetation buffer area crossed by the pipeline right-of-way and TWS only if absolutely necessary [Section 8.1]. • Fell trees away from watercourses and away from limits of the construction right-of-way to reduce damage to streambanks, beds and adjacent trees. Hand clear the area, if necessary, to reduce disturbance [Section 8.1]. • Adhere to clearing guidelines for protection of streams and wetlands provided in the *Forest Practices Code*, and the *Riparian Management Area Guidebook* in BC, where riparian management zones (widths) are identified based on stream or wetland class [Section 8.1]. Bank and Riparian Restoration • Recontour the construction right-of-way and stabilize approach slopes at watercourse crossings [Section 8.6]. • Return the bed and banks of each crossing as close as feasible to their pre-construction contours (slope and height). Take appropriate measures to reduce the risk of sloughing of the streambanks following construction [Section 8.7]. • Install coir or other biodegradable erosion control fabric approved by the Inspector(s) on disturbed portions of the banks [Section 8.7]. • Maintain sediment fences or equivalent sediment control structure in place at the base of approach slopes until revegetation of the construction right-of- way is complete [Section 8.7].	• Riparian habitat loss or alteration due to construction activities.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Riparian habitat loss or alteration during construction (cont'd)	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Access roads Black Pines Pump Station Power line Kingsvale Pump Station Power line	Footprint	• Seed riparian areas with an approved annual or perennial grass cover crop or native grass mix as soon as feasible after construction. Install temporary erosion control measures such as temporary berms, sediment fences, mounds or cross ditches within 24 hours of backfilling banks and approach slopes of water crossings at any location where runoff from the construction right-of-way may flow into a watercourse [Section 8.6]. • Seed disturbed areas on the banks and approaches as soon as practical with an approved grass cover crop species or native grass seed mix and implement sediment control measures to stabilize watercourse banks and prevent sedimentation of the watercourse, respectively [Section 8.7].	• See above.
1.2 Riparian habitat alteration during maintenance and operation	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effect 1.1 of this table.	• Clearing or disturbance of riparian habitat during maintenance and operation.
1.3 Riparian habitat loss and alteration from accidental drilling mud release	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	RSA	• Excavate the entry and expected exit sites to provide for the containment of drilling mud and cuttings during a HDD. Ensure the excavations are located far enough from the watercourse and in containment berms or tanks that are large enough to contain the anticipated maximum volume of drilling mud above the high watermark of the watercourse [Section 8.7]. • Follow the drilling mud frac-out monitoring and other measures outlined in the Drilling Mud Release Contingency Plan (see Appendix B) during horizontal directional drilling [Section 8.7].	• Alteration of riparian habitat from accidental drilling mud release and associated clean up activities.
1.4 Contamination from spills during construction and maintenance	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Black Pines Pump Station Power line Kingsvale Pump Station Power line Terminals Edmonton Sumas Burnaby (hydrostatic testing) Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	• Review and adhere to the general mitigation measures provided in Section 7.0 related to equipment washing, inspection of hydraulic, fuel and lubrication systems of equipment, equipment servicing and refuelling as well as fuel storage in proximity to watercourses during water crossing construction [Section 8.7]. • Use non-toxic, biodegradable hydraulic fluids in all equipment that will work instream if/when flowing water will be encountered during construction or in wetland and/or lakes if requested by the Inspector(s) [Section 8.7]. • Do not store fuel, oil or hazardous material within 300 m of a watercourse/wetland/lake [Section 7.0]. • Ensure that any approvals, licenses and permits that are necessary are in place prior to commencing applicable hydrostatic testing activities [Section 8.5]. • Obtain all applicable regulatory authority approvals for water withdrawal and discharge to allow for hydrostatic testing of the facility and ensure conditions of approvals are satisfied during water withdrawal for hydrostatic testing [Section 8.3 of the Facilities EPP].	• Contamination of riparian habitat from spills during construction and maintenance.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.4 Contamination from spills during construction and maintenance (cont'd)	See above	See above	• Ensure that test water withdrawn from one drainage basin will not enter surface waters in another drainage basin [Section 8.5]. • Ensure pump intakes are placed in a manner that reduces or avoids disturbance to the streambed and are screened in accordance with the DFO screening requirements, to prevent the entrapment of fish or wildlife (*Freshwater Intake End-of-Pipe Fish Screen Guideline)* [Section 8.5]. • Utilize screen pump intakes with a maximum mesh size of 2.54 mm and with a maximum approach velocity of 0.038 m/s, where fish habitat is present [Section 8.5].	• See above.
2. Fish and Fish Habitat Indicator – Instream Habitat				
2.1 Instream habitat alteration	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Terminals Edmonton Sumas Burnaby (hydrostatic testing) Pump Stations Black Pines Kingsvale (vehicle crossings for power line construction) Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	General • Adhere to water crossing requirements provided in environment resource-specific mitigation tables for aquatic resources provided in Appendix I [Section 7.0]. • Trans Mountain will work with regulatory authorities to determine the necessary approvals, licenses and permits needed for construction of the pipeline or associated components prior to the commencement of the permitted activity on any given pipeline spread. The contractor(s), subcontractors and the Inspector(s) will be provided with copies of all approvals/licenses and permits including the most recent updates and revisions, and will comply with all conditions presented to Trans Mountain. Trans Mountain will resolve any inconsistencies between approval/permit conditions and contract documents prior to commencement of the construction activity [Section 3.0]. • Review and adhere to applicable instream timing constraints (RAP/least-risk window) and all resource-specific measures outlined in the mitigation tables for aquatic resources provided in Appendix I [Section 8.7]. • Follow applicable DFO Operational Statements outlining conditions and measures to avoid serious harm to fish or any permanent alteration to, or destruction of, fish habitat when working in or near a watercourse/wetland/lake that has been identified as providing fish habitat [Section 8.7]. • Ensure all necessary equipment, personnel and materials are on-site and ready for installation prior to commencing instream work. Complete all work as quickly as practical to limit the duration of disturbance [Section 8.7]. • Re-establish streambanks and approaches immediately following construction of water crossings as outlined in the Reclamation Management Plan (see Appendix C) [Section 8.6]. Vehicle Crossings • Install, use and remove bridges in accordance with the measures identified in the DFO *Operational Statement for Clear-Span Bridges* and *Operational Statement for Bridge Maintenance* [Section 8.7].	• Alteration of instream habitat within the ZOI.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.1 Instream habitat alteration (cont'd)	See above	RSA	• Design, construct and abandon ice bridge and snow fill vehicle crossings at watercourses/wetlands/lakes in accordance with the applicable DFO *Operational Statement for Ice Bridges and Snow Fills* [Section 8.7]. Trenched Crossing Technique • Conduct an open-cut crossing of seasonally dry or frozen to the bottom watercourses and an isolated crossing at select crossings (see Appendix I) in Alberta in accordance with the *Alberta Operational Statement for Isolated or Dry Open-cut Stream Crossings* (see Drawing [Watercourse Crossing – Open Cut Method for Dry/Frozen Watercourses] provided in Appendix R) [Section 8.7]. • Conduct typical open cut of seasonally dry or frozen to the bottom watercourses in BC in accordance with the Pacific Region *Operational Statement for Dry Open-cut Stream Crossings* [Section 8.7]. • Isolated BC pipeline crossings are not included under the Pacific Region DFO's *Operational Statement for Isolated or Dry Open-cut Stream Crossings* [Section 8.7]. • Ensure all water intakes are screened in accordance with the DFO's *Freshwater End-of-Pipe Fish Screen Guideline*. Ensure the screens are free of debris during pumping [Section 8.7]. • Ensure that pump intakes avoid or reduce disturbance of the streambed and are screened with a maximum mesh size of 2.54 mm and sized to limit the approach velocity to not exceed 0.038 m/s [Section 8.7]. Trenchless Crossings • Construct trenchless crossings in accordance with the COP requirements and the conditions of the DFO's *Operational Statement for High-pressure Directional Drilling* (Alberta and the DFO's Operational Statement for Directional Drilling (BC) [Section 8.7]. • Plan for and use the procedures for a HDD or other trenchless crossing in accordance with those provided in the Horizontal Directional Drilling/Trenchless Planning and Procedures Management Plan (see Appendix C) [Section 8.7]. • Cease trenchless crossing work immediately and refer to the Drilling Mud Release Contingency Plan (see Appendix B) in the event that an inadvertent release of drilling mud has occurred and the material is or may enter the watercourse or affect other sensitive environmental or land use features [Section 8.7]. Monitoring • Monitor to assess the immediate effects of crossing construction, where warranted. Also monitor sediment release (*i.e.*, turbidity and total suspended solids) throughout the crossing construction period, when warranted in accordance with the monitoring measures provided in the Water Crossing Construction Monitoring Plan [Section 8.7]. • See additional monitoring measures in Section 8.7 of the Pipeline EPP.	• See above.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.1 Instream habitat alteration (cont'd)	See above	RSA	Hydrostatic Testing • Confirm that approvals/notifications are in place for the intended test water sources and that adequate streamflow/volume is present for the testing program [Section 8.5]. • The withdrawal rate and volume will not exceed 10% of the flow rate of the watercourse or of the volume of the body of water unless otherwise approved by the appropriate authority when withdrawing water in Alberta [Section 8.5]. • Utilize screen pump intakes with a maximum mesh size of 2.54 mm and with a maximum approach velocity of 0.038 m/s, where fish habitat is present [Section 8.5]. • See additional notification, sampling and reporting measures in Section 8.5 of the Pipeline EPP.	• See above.
2.2 Instream habitat alteration from accidental drilling mud release	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	LSA	• Construct trenchless crossings in accordance with the COP requirements and the conditions of the *DFO's Operational Statement for High-pressure Directional Drilling* (Alberta) and the DFO's Operational Statement for Directional Drilling (BC) [Section 8.7]. • Monitor to assess the immediate effects of crossing construction, if warranted. Also monitor sediment release (*i.e.,* turbidity and total suspended solids) throughout the crossing construction period, if required [Section 8.7]. • Cease trenchless crossing work immediately and refer to the Drilling Mud Release Contingency Plan (see Appendix B) in the event that an inadvertent release of drilling mud has occurred and the material is or may enter the watercourse or affect other sensitive environmental or land use features [Section 8.7]. • Assign the Inspector(s), Qualified Aquatic Environmental Specialist (QAES) or Qualified Environmental Professional (QEP) with expertise in the containment of inadvertent release of drilling mud and clean up to HDDs under a watercourse (see Drilling Mud Release Contingency Plan in Appendix B) [Section 8.7].	• Alteration of instream habitat from drilling mud release.
2.3 Contamination from spills during construction	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Terminals Edmonton Sumas Burnaby (hydrostatic testing) Black Pines Pump Station Power line Kingsvale Pump Station Power line Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	• Review and adhere to the general mitigation measures in Section 7.0 related to equipment washing, inspection of hydraulic, fuel and lubrication systems of equipment, equipment servicing and refuelling as well as fuel storage in proximity to watercourses during water crossing construction [Section 8.7]. • Do not store fuel, oil, or hazardous material within 300 m of a watercourse/wetland/lake [Section 7.0]. • Use non-toxic, biodegradable hydraulic fluids in all equipment that will work instream if/when flowing water will be encountered during construction or in wetland and/or lakes if requested by the Inspector(s) [Section 8.7].	• Contamination of instream habitat from spills during construction.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.3 Contamination from spills during construction (cont'd)	See above	See above	• Maintain the identified separation distances between the following areas and a watercourse/wetland/lake when constructing the facility site, unless otherwise approved: • fuel or hazardous material storage site - 300 m; • cleared area – 100 m; • burning site – 100 m; • subsoil pile – 100 m; and • oil change area – 100 m [Section 7.0 of the Facilities EPP]. • See recommended mitigation measures for potential effect 1.4 of this table.	• See above.
2.4 Increased access to instream habitat during operation	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Access roads	RSA	• Follow the measures in the Traffic and Access Control Management Plan (see Appendix C) [Section 8.7]. • Install tree/shrub plantings at potential access points to the construction right-of-way to visually screen the construction right-of-way (see Drawing [Vegetation Screen] provided in Appendix R) [Section 8.6]. • Rollback slash and salvageable timber at locations indicated on Environmental Alignment Sheets to prevent access along the construction right-of-way. Spread evenly over the construction right-of-way. Rollbacks will not be walked on [Section 8.6].	• Disturbance to instream habitat due to a potential increase in access during operations.
3. Fish and Fish Habitat Indicator – Fish Mortality or Injury				
3.1 Fish mortality or injury during construction	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Access roads Pump Stations Black Pines Kingsvale (vehicle crossings for power line construction) Terminals Edmonton Sumas Burnaby (hydrostatic testing) Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	• Review and adhere to applicable instream timing constraints (RAP/least-risk window) and all resource-specific measures outlined in the mitigation tables for aquatic resources provided in Appendix I [Section 8.7]. • Determine the presence of any aquatic or riparian plants and pests prior to the commencement of construction activities within the riparian buffer. Notify the contractor of any special measures to be implemented to prevent the transfer of these organisms from one watercourse to another [Section 8.7]. • Follow applicable DFO Operational Statements outlining conditions and measures to avoid serious harm to fish or any permanent alteration to, or destruction of, fish habitat when working in or near a watercourse/wetland/lake that has been identified as providing fish habitat [Section 8.7]. • Prohibit recreational fishing by Project personnel on or in the vicinity of the construction right-of-way. The use of the construction right-of-way to access fishing sites is prohibited [Section 7.0]. • Follow appropriate procedures provided in *Guidelines for the Use of Explosives in or near Canadian Fisheries Waters* if blasting is necessary. Blasting within 300 m of a watercourse/wetland/lake will be reduced or avoided to the extent feasible (see Watercourse Crossing Management Plan provided in Appendix C) [Section 8.3].	• Increased fish mortality or injury due to construction activities.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.1 Fish mortality or injury during construction (cont'd)	See above	RSA	• Ensure all water intakes are screened in accordance with the DFO's *Freshwater End-of-Pipe Fish Screen Guideline*. Ensure the screens are free of debris during pumping [Section 8.7]. • Monitor to assess the immediate effects of crossing construction, if warranted. Also monitor sediment release (*i.e.,* turbidity and total suspended solids) throughout the crossing construction period, if required [Section 8.7]. • Assign a QAES/QEP to salvage fish with an electrofishing from the isolated area prior to and during dewatering and trenching at isolated water crossings in accordance with the Fish Research License in Alberta and the Fish Collection Permit in BC (see Appendix D) if those permits are determined to be necessary. Note that the application for a Fish Research Permit and a Fish Collection Permit is to be submitted 10 working days (minimum) prior to the scheduled isolation of the watercourse. Release all captured fish to areas downstream of the crossing that provide suitable habitat [Section 8.7]. • Clean fish salvage equipment (*e.g.,* waders, boots, nets) of soil, and disinfect with 100 mg/L chlorine bleach before using in any watercourse to prevent the spread of pathogens (*e.g.,* whirling disease) and/or invasive plant species. Ensure that washed off soil is disposed of at a location that will prevent the reintroduction of these untreated materials into a watercourse [Section 8.7]. • Prohibit recreational fishing by Project personnel on or in the vicinity of the facility footprint. The use of the facility by construction personnel to access fishing sites will be prohibited [Section 7.0 of the Facilities EPP]. • See recommended mitigation measures outlined in potential effect 1.4. • See hydrostatic testing measures outlined in potential effect 2.1 of this table.	• See above.
3.2 Fish mortality or injury from spills during construction	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Access roads Black Pines Pump Station Power line Kingsvale Pump Station Power line Terminals Edmonton Sumas Burnaby (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effect 3.1 of this table.	• Increased fish mortality or injury from spills during construction.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.3 Fish mortality or injury due to accidental release of hazardous materials during power line construction	Black Pines Pump Station Power line Kingsvale Pump Station Power line	RSA	• See recommended mitigation measures outlined in potential effect 1.1 of Table 7.4.3.-1 Water Quality and Quantity.	• No residual effect identified.
3.4 Increased suspended sediment concentrations in the water column during instream construction	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Access roads Pump Stations Black Pines Kingsvale (vehicle crossings for power line construction) Terminals Edmonton Sumas Burnaby (hydrostatic testing) Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	General • Grade away from watercourses/wetlands/lakes to reduce the risk of introduction of soil and organic debris. Do not place windrowed or fill material in watercourses/wetlands/lakes during grading. Keep wetland soils separate from upland soils [Section 8.2]. • Ensure temporary berms and/or sediment fence installed following grading (see Section 8.2) will adequately control runoff from entering the open trench in the vicinity of water crossings [Section 8.3]. • Install a temporary sediment barrier (*e.g.,* sediment fences), where warranted, to eliminate the flow of sediment from spoil piles and disturbed areas into nearby watercourses/wetlands/lakes (see Drawing [Sediment Fence] provided in Appendix R) [Section 8.7]. • Inspect temporary sediment control structures (*e.g.,* sediment fences, subsoil berms) installed on approach slopes, on a daily basis throughout crossing construction. Repair the structures, if warranted, before the end of the working day [Section 8.7]. • Ensure all necessary equipment, personnel and materials are on-site and ready for installation prior to commencing instream work. Complete all work as quickly as practical to limit the duration of disturbance [Section 8.7]. • Develop water quality monitoring plans, where required, to monitor for suspended sediment during HDD, and select isolated trenched crossings of watercourses with high sensitivity fish habitat, or open-cut crossing construction activities where flow is present. If monitoring reveals that sediment values are approaching threshold values, the water quality monitors will notify the Lead Environmental Inspector and Inspector(s) who, with the Construction Manager and contractor, will develop corrective actions [Section 8.7]. • Monitor temporary vehicle crossings to ensure that erosion control measures are adequate and streamflow is not disrupted [Section 8.7]. • See additional monitoring measures in Section 8.7 of the Pipeline EPP. Trenched Crossings • Conduct an open-cut crossing of seasonally dry or frozen to the bottom watercourses and an isolated crossing at select crossings (see Appendix I) in Alberta in accordance with the *Alberta Operational Statement for Isolated or Dry Open-cut Stream Crossings* (see Drawing [Watercourse Crossing – Open Cut Method for Dry/Frozen Watercourses] provided in Appendix R) [Section 8.7].	• Increased fish mortality or injury due to suspended sediment during instream construction.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.4 Increased suspended sediment concentrations in the water column during instream construction (cont'd)	See above	RSA	• Construct the crossing in accordance with the COP (Alberta only) requirements and in accordance with the conditions of the DFO's *Operational Statement for Isolated or Dry Open-cut Stream Crossings* or other DFO conditions [Section 8.7]. • Isolated BC pipeline crossings are not included under the Pacific Region DFO's *Operational Statement for Isolated or Dry Open-cut Crossings* [Section 8.7]. • Dewater the segment of the watercourse between the dams, if feasible and safe to do so. Pump any sediment-laden water out between the dams to well-vegetated lands, away from the watercourse or to settling ponds [Section 8.7]. • Remove any accumulations of sediment within the isolation areas that resulted from crossing construction. Spread all sediment and unused trench spoil removed from the watercourse at a location above the high water mark where the materials will not directly re-enter the watercourse [Section 8.7]. • Ensure that water from flumes, dam and pumps, diversion or other methods does not cause erosion or introduce sediment into the channel. If warranted, place rock rip rap, tarpaulins, plywood sheeting or other materials to control erosion at the outlet of pump hoses and flumes. Supplement the erosion control materials, if warranted, to control any erosion [Section 8.7]. Vehicle Crossings • Use the vehicle crossings at watercourses crossed by access roads identified in Section 9.0 within the aquatic resources tables (see Appendix I) and on the Environmental Alignment Sheets [Section 8.7]. • Install temporary bridges at locations identified in the environmental resource-specific mitigation tables for Aquatic resources provided in Appendix I. Ensure bridges are clean prior to installation and dispose of soil at an appropriate location (see Drawing [Vehicle Crossing – Ramp and Culvert] provided in Appendix R) [Section 8.7]. • Implement erosion control measures as soon as a disturbance of the vegetation mat occurs [Section 8.7]. • Stabilize and revegetate areas disturbed during installation and removal of a bridge; install erosion control measures, where warranted, to control surface erosion until vegetation is established [Section 8.7]. • Install clean snowfills during frozen conditions at locations identified in the environmental resource-specific mitigation tables for aquatic resources provided in Appendix I, and at all minor and intermittent watercourses (see Environmental Alignment Sheets) [Section 8.7]. • See recommended mitigation measures for potential effect 1.2 outlined in Table 7.2.3-2 Water Quality and Quantity.	• See above.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.5 Increased suspended sediment concentrations in the water column from accidental drilling mud release	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby	LSA	• See recommended mitigation measures outlined in potential effect 2.2 of this table.	• Increased fish mortality or injury due to suspended sediment from drilling mud release.
3.6 Increased access to fish and fish habitat during operations	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge	LSA	• See recommended mitigation measures outlined in potential effect 2.4 of this table.	• Increased fish mortality or injury due to a potential increase in access during operations.
3.7 Blockage of fish movements	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Access roads	LSA	• Ensure maintenance of downstream flow conditions (*i.e.,* quantity and quality) at all times when constructing an isolated crossing. If a pump-around method is used to maintain downstream flow, back-up pumping capacity must be onsite and ready to take over pumping immediately if operating pumps fail. Pumps are to be continuously monitored to ensure flow is maintained at all times until the dam materials are removed and normal flow is restored to the channel [Section 8.7]. • Design, construct and abandon ice bridge and snow fill vehicle crossings at watercourses/wetlands/lakes in accordance with the applicable DFO *Operational Statement for Ice Bridges and Snow Fills* [Section 8.7]. <u>Vehicle Crossings</u> • Ensure temporary vehicle crossing structures do not disrupt fish passage at fish-bearing watercourses [Section 8.7]. • Ensure temporary vehicle crossing structures do not disrupt fish passage at fish-bearing watercourses and do not interfere with or impede flow or navigation at any location [Section 8.7]. • Install crossings structures as identified in the Aquatics Resource-specific Mitigation Tables (see Appendix I) [Section 8.7]. • Construct or install temporary vehicle access across watercourses and adjacent to wetlands and lakes in a manner that follows provincial and federal guidelines [Section 8.7].	• Temporary blockage of fish movements.
3.8 Interbasin transfer of aquatic organisms	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Terminals Edmonton Sumas Burnaby (hydrostatic testing) Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	• Determine the presence of any aquatic or riparian plants and pests prior to the commencement of construction activities within the riparian buffer. Notify the contractor of any special measures to be implemented to prevent the transfer of these organisms from one watercourse to another [Section 8.7]. • Ensure that test water withdrawn from one drainage basin is not allowed to enter natural waters of another drainage basin [Section 8.5]. • Clean fish salvage equipment (*e.g.,* waders, boots, nets) of soil, and disinfect with 100 mg/L chlorine bleach before using in any watercourse to prevent the spread of pathogens (*e.g.*, whirling disease) and/or invasive plant species. Ensure that washed off soil is disposed of at a location that will prevent the reintroduction of these untreated materials into a watercourse [Section 8.7].	• No residual effect identified.

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.8 Interbasin transfer of aquatic organisms (cont'd)	See above	See above	• Install trench breakers if the banks are composed of organic materials as noted in Section 8.0 [Section 8.7].	• See above.
3.9 Effects on fish species of concern	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Terminals Edmonton Sumas Burnaby (hydrostatic testing) Pipeline Reactivation Hinton to Hargreaves Darfield to Black Pines (hydrostatic testing)	RSA	• Implement applicable measures from the Fish Species of Concern Contingency Plan (see Appendix B) should fish species of concern be discovered during construction [Section 8.7]. • See recommended mitigation measures outlined in potential effects 3.1 to 3.6 of this table. • See recommended mitigation measures outlined in potential effect 2.3 of this table.	• Fish species of concern may be affected by an increase in suspended sediment concentration, habitat alteration within the ZOI and increased potential for mortality and injury.
4. Fish and Fish Habitat Indicator – Arctic Grayling (Alberta Indicator Species)				
4.1 Contamination, loss or alteration of Arctic grayling riparian habitat	Edmonton to Hinton Pipeline Reactivation Hinton to Hargreaves (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on Arctic Grayling resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.
4.2 Contamination, loss or alteration of Arctic grayling instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
4.3 Mortality or injury of Arctic grayling		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.	
5. Fish and Fish Habitat Indicator – Athabasca Rainbow Trout (Alberta Indicator Species)				
5.1 Contamination, loss or alteration of Athabasca rainbow trout riparian habitat	Edmonton to Hinton Pipeline Reactivation Hinton to Hargreaves (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on Athabasca rainbow trout resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.
5.2 Contamination, loss or alteration of Athabasca rainbow trout instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
5.3 Mortality or injury of Athabasca rainbow trout		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.	
6. Fish and Fish Habitat Indicator – Bull Trout (Alberta Indicator Species)				
6.1 Contamination, loss or alteration of bull trout riparian habitat	Edmonton to Hinton Pipeline Reactivation Hinton to Hargreaves (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on bull trout resulting from contamination; loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.
6.2 Contamination, loss or alteration of bull trout instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
6.3 Mortality or injury of bull trout		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.	

TABLE 7.2.7-2 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
7. Fish and Fish Habitat Indicator – Burbot (Alberta Indicator Species)				
7.1 Contamination, loss or alteration of burbot riparian habitat	**Edmonton to Hinton** **Edmonton Terminal** Hydrostatic testing **Pipeline Reactivation** Hinton to Hargreaves (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on burbot resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.
7.2 Contamination, loss or alteration of burbot instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
7.3 Mortality or injury of burbot		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.	
8. Fish and Fish Habitat Indicator – Northern Pike (Alberta Indicator Species)				
8.1 Contamination, loss or alteration of northern pike riparian habitat	**Edmonton to Hinton** **Edmonton Terminal** (hydrostatic testing) **Pipeline Reactivation** Hinton to Hargreaves (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on northern pike resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.
8.2 Contamination, loss or alteration of northern pike instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
8.3 Mortality or injury of northern pike		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.	
9. Fish and Fish Habitat Indicator – Walleye (Alberta Indicator Species)				
9.1 Contamination, loss or alteration of walleye riparian habitat	**Edmonton to Hinton** **Edmonton Terminal** Hydrostatic testing **Pipeline Reactivation** Hinton to Hargreaves (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on walleye resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.
9.2 Contamination, loss or alteration of walleye instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
9.3 Mortality or injury of walleye		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.	
10. Fish and Fish Habitat Indicator – Bull Trout/Dolly Varden (BC Indicator Species)				
10.1 Contamination, loss or alteration of bull trout/Dolly Varden riparian habitat	**Hargreaves to Darfield** **Black Pines to Hope** **Hope to Burnaby** **Pump Stations** Black Pines Kingsvale (vehicle crossings for power line construction) **Terminal** Sumas (hydrostatic testing) **Pipeline Reactivation** Darfield to Black Pines (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on bull trout/Dolly Varden resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.
10.2 Contamination, loss or alteration of bull trout/Dolly Varden instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
10.3 Contamination, mortality or injury of bull trout/Dolly Varden		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.

14. Fish and Fish Habitat Indicator – Rainbow Trout/Steelhead (BC Indicator Species)				
14.1 Contamination, loss or alteration of rainbow trout/steelhead riparian habitat	Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge] Pump Stations Black Pines Kingsvale (vehicle crossings for power line construction) Terminals Sumas Burnaby (hydrostatic testing) Pipeline Reactivation Darfield to Black Pines (hydrostatic testing)	RSA	• See recommended mitigation measures outlined in potential effects 1.1 to 1.4 of this table.	• Combined effects on rainbow trout/steelhead resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat;and mortality or injury.
14.2 Contamination, loss or alteration of rainbow trout/steelhead instream habitat		RSA	• See recommended mitigation measures outlined in potential effects 2.1 to 2.4 of this table.	
14.3 Mortality or injury of rainbow trout/steelhead		RSA	• See recommended mitigation measures outlined in potential effects 3.1 to 3.7 of this table.	

Notes: 1 LSA = Fish and Fish Habitat LSA; RSA = Aquatics RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

7.2.7.5 Potential Residual Effects

The potential residual environmental effects on fish and fish habitat indicators associated with the construction and operations of the Project (Table 7.2.7-2) are:

- riparian habitat loss or alteration due to construction activities;
- clearing or disturbance of riparian habitat during maintenance and operations;
- alteration of riparian habitat from accidental drilling mud release and associated clean up activities;
- contamination of riparian habitat from spills during construction;
- alteration of instream habitat within the ZOI;
- alteration of instream habitat from drilling mud release;
- contamination of instream habitat from spills during construction and maintenance;
- disturbance to instream habitat due to a potential increase in access during operations;
- increased fish mortality or injury due to construction;
- increased fish mortality or injury due to spills during construction;
- increased fish mortality or injury due to suspended sediment during instream construction;
- increased fish mortality or injury due to suspended sediment from drilling mud release;
- increased fish mortality or injury due to a potential increase in access during operations;
- temporary blockage of fish movements;
- fish species of concern may be affected by an increase in suspended sediment concentration, habitat alteration within the ZOI and increased potential for mortality or injury;

- combined effects on Alberta indicator species (*i.e.*, Arctic grayling, Athabasca rainbow trout, bull trout, burbot, northern pike and walleye) resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury; and
- combined effects on BC indicator species (*i.e.*, bull trout/Dolly Varden, Chinook salmon, coho salmon, cutthroat trout, rainbow trout/steelhead) resulting from contamination, loss or alteration of riparian habitat; contamination, loss or alteration of instream habitat; and mortality or injury.

The potential effects associated with the interbasin transfer of aquatic organisms are predicted to be eliminated through the implementation of mitigation measures (Table 7.2.7-2) and, therefore, no residual effect is identified.

The potential effects associated with the fish mortality or injury due to accidental release of hazardous materials during power line construction are predicted to be eliminated through the implementation of mitigation measures (Table 7.2.7-2) and, therefore, no residual effect is identified.

7.2.7.6 Significance Evaluation of Potential Residual Effects

A quantitative analysis was undertaken to evaluate the significance of the potential residual environmental effects for the disturbance of riparian habitat and instream habitat indicators as these changes over the baseline data were quantifiable. However, where there are no standards, guidelines, objectives or other established and accepted ecological thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method that is based on available research literature, field experience and professional judgment is considered to be the appropriate method for determining the significance of the anticipated residual environmental effects. Consequently, the qualitative assessment of fish and fish habitat is considered to be the most appropriate method with the evaluation of significance of the potential residual effects relying on the professional judgment of the assessment team in consideration of CCME guidelines and federal and provincial guidelines, where applicable.

Table 7.2.7-3 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the Project on fish and fish habitat indicators. The rationale use in the evaluation of significance of each of the residual environmental effects is provided below.

TABLE 7.2.7-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON FISH AND FISH HABITAT

				Temporal Context						
	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Duration	Frequency	Reversibility	Magnitude	Probability	Confidence	Significance[2]
1.	Fish and Fish Habitat Indicator – Riparian Habitat									
1(a)	Riparian habitat loss or alteration due to construction activities.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Low	High	High	Not significant
1(b)	Clearing or disturbance of riparian habitat during maintenance and operations.	Negative	Footprint	Immediate to short-term	Occasional	Medium to long-term	Low	High	High	Not significant

Notes: 1 LSA = Fish and Fish Habitat LSA; RSA = Aquatics RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Fish and Fish Habitat Indicator – Riparian Habitat

The following provides the evaluation of significance of potential residual effects on the riparian habitat indicator related to construction, operations and maintenance activities and contamination from small spills during construction.

Riparian Habitat Loss or Alteration Due to Construction

The components of the Project which may affect the riparian habitat include the construction and operations of the proposed pipeline, temporary facilities (*i.e.,* through construction of access roads), and pump stations (*i.e.,* power lines at Black Pines and Kingsvale), activities associated with pipeline reactivation and the tanks and associated terminals are not expected to cause a loss or alteration of riparian habitat. No potential effects were identified for riparian habitat resulting from construction and operations activities at the Westridge Marine Terminal.

Riparian vegetation within the construction right-of-way and temporary workspace will be disturbed at all trenched (*i.e.*, isolated or open cut) watercourse crossings and watercourses where a temporary vehicle crossing will be installed. The impact balance of this residual effect is considered to be negative. During construction, disturbance to riparian vegetation will be kept to a minimum, leaving as much existing riparian vegetation intact as practical and efforts to control sedimentation and erosion in disturbed areas will be implemented. Alteration to riparian vegetation will also be reduced during frozen ground conditions. Disturbed riparian areas will be seeded following construction with appropriate native seed mix along with a quick establishing cover crop. Grasses are expected to be restored within the growing season following construction, but it will take several years for the canopy to be restored. Revegetation mitigation measures are presented in the Pipeline EPP (Volume 6B).

Riparian habitat revegetation plans for the TMX Anchor Loop Project included determining riparian plant species and numbers to be used at each site based on detailed site assessments to determine the biophysical parameters at each watercourse crossing (TERA 2009a). Monitoring 1 year after construction revealed that remedial planting was required at 10 fish-bearing watercourses (of 34 assessed) (TERA 2009b). Only 3 of 39 fish-bearing watercourses required supplemental planting 2 years following construction (TERA 2011a). By 4 years post-construction, all outstanding issues relating to riparian loss and/or alteration at all watercourses (*i.e.*, fish-bearing and nonfish-bearing) were resolved (TERA 2013a). Results of the post-construction environmental monitoring also indicated the effectiveness of several mitigation measures recommended for the Project in Table 7.2.7-2. When grubbing was avoided in riparian areas adjacent to watercourse crossings, deciduous plants re-sprouted in the spring following clearing and native plants established from seed in the undisturbed surface soil (TERA 2013a). In addition, the manual removal of vegetation in riparian areas was found to be effective in the control or suppression of non-native broadleaf weeds (TERA 2013a). If necessary, trees will be cleared by hand to reduce disturbance to riparian areas (Section 8.1 of the Pipeline EPP [Volume 6B]).

Silt runoff from construction activities was a concern raised by participants at the Burnaby Community Workshop. According to participants, Brunette River, Silver, Eagle and Stoney creeks are watercourses of most concern for riparian habitat loss or alteration in this area. The successful implementation of the recommended mitigation measures should address the concerns of participants at the Burnaby Community Workshop.

The maximum riparian area that may be disturbed by construction of the proposed pipeline is 334.6 ha, or 0.05% of the total riparian area within the Aquatics RSA (Table 7.2.7-4). This maximum disturbance as a result of pipeline construction would occur if the entire riparian area, to the width of the construction right-of-way and 30 m from the top of the bank was removed at every watercourse crossing, however, the actual disturbance to riparian habitat is expected to be less. Some watercourses will be crossed using a trenchless method (reducing the effects to riparian habitat), in addition, some crossings will not have 30 m of riparian habitat from the top of the banks (*i.e.,* in the White Area of Alberta). Furthermore, clearing of riparian vegetation will only occur within the pipeline easement and temporary workspace will not be cleared within the riparian buffer. Additional riparian habitat disturbance may occur at vehicle crossings for access roads to temporary facilities and other Project components, however, these details are currently unknown and this disturbance is expected to be minor.

TABLE 7.2.7-4

PROJECT DISTURBANCE OF RIPARIAN HABITAT WITHIN THE AQUATICS RSA

Province	Area of Riparian Habitat in RSA (ha)	Area of Disturbed Riparian Habitat (ha)	% of Riparian Habitat Disturbed
Alberta[1]	193,182.1	63.1	0.03
British Columbia[2]	524.747.0	271.5	0.05
TOTALS	717,929.1	334.6	0.05

Notes: 1 The Middle North Saskatchewan River watershed is not included because disturbance of riparian areas as the Project is located within the City of Edmonton in this watershed, and the City of Edmonton has been excluded from the quantitative analysis (Section 8.1.5).

2 The Lower Fraser River and Squamish watersheds are not included because disturbance of riparian areas as the Project is located within the Lower Mainland Developed Area (LMDA) in both of these watersheds, and the LMDA has been excluded from the quantitative analysis (Section 8.1.5).

3 Calculations based on an average of 30 m riparian area on each bank at all waterbodies.

4 Calculations based on footprint disturbances provided in Table 8.1-1 and are approximate.

The residual effect of pipeline construction on clearing riparian vegetation, although negative, is considered to be of low magnitude given the implementation of industry standard and provincially and federally recommended mitigation measures and monitoring of revegetation success at water crossings post-construction. The residual effect is also considered to be reversible in the medium to long-term, depending on the pre-existing vegetation community (*e.g.,* shrubs regenerate within several years, however, tree regrowth is expected to extend into the long-term) (Table 7.2.7-3, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – clearing or disturbance of riparian vegetation is confined to the Project Footprint.
- Duration: short-term – the event causing the alteration of riparian vegetation is construction of the various components of the Project (*e.g.*, pipeline and temporary vehicle crossings).
- Frequency: isolated – the event causing clearing or disturbance of riparian vegetation (*i.e.,* construction of the pipeline and temporary vehicle crossings) is confined to a specific period.
- Reversibility: medium to long-term – depending upon the pre-existing vegetation community (*e.g.,* grasses, shrubs and/or trees).
- Magnitude: low – based on implementation of mitigation measures, including revegetation, and the results of post-construction environmental monitoring programs which demonstrate the effectiveness of the measures proposed.

- Probability: high – alteration of riparian vegetation is expected to occur at all trenched (*i.e.*, isolated or open cut) watercourse crossings and vehicle crossings where riparian vegetation exists.
- Confidence: high – based on a good understanding by the assessment team of trenched and vehicle crossing methods and associated affects on riparian vegetation.

Clearing or Disturbance of Riparian Habitat During Maintenance and Operations

Routine vegetation control along the proposed pipeline right-of-way and reactivated pipeline segments during operations will exclude riparian areas. However, a situation may occur during the life of the operating pipeline where riparian vegetation disturbance may be necessary to accommodate maintenance activities (*e.g.,* in the event of a flood event that causes scouring over the pipeline trench that would require measures to restore depth of cover and pipe integrity or an integrity dig). The residual effect of clearing riparian habitat during pipeline operations is of low magnitude and reversible in the medium to long-term (Table 7.2-7.3, point 1[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – clearing or disturbance of riparian vegetation is confined to the Project Footprint.
- Duration: immediate to short-term – the event causing alteration of riparian vegetation during operations is maintenance activities which may take less than two days (*i.e.,* immediate) or may take more than two days but less than 1 year (*i.e.,* short-term).
- Frequency: occasional – any maintenance activities required at watercourse crossings will occur intermittently and sporadically over the assessment period.
- Reversibility: medium to long-term – depending upon the pre-existing vegetation community (*e.g.,* shrubs or trees) and the extent of clearing or alteration of riparian vegetation required for maintenance activities to take place.
- Magnitude: low – based on the implementation of industry standard and provincially and federally recommended mitigation measures during operations phases of the Project and the results of post-construction environmental monitoring programs which demonstrate the effectiveness of the measures proposed.
- Probability: high – clearing within the riparian area may occur as a result of integrity digs during operations.
- Confidence: high – based on the professional experience of the assessment team.

Alteration of Riparian Habitat from Accidental Drilling Mud Release and Associated Clean Up Activities

During HDD crossings for the Project, monitoring of drilling fluid volumes and pressure, as well as monitoring of sediment concentrations in the watercourse and terrestrial frac-outs are expected to reduce the potential for a drilling mud release to affect a watercourse. If a release on-land (*i.e.*, terrestrial) were to occur, the inert nature of the bentonite clay used would not contaminate the riparian area. However, clean up and reclamation measures may result in some riparian habitat alteration. During the Surrey ESA Workshop, participants raised concerns over the introduction of large quantities of sand into watercourses, as has happened with past events (*i.e.,* construction of a gas pipeline in 1979). However, this is not anticipated for the Project given the use of bentonite clay in the drilling mud. There were no trenchless crossings during construction of the TMX Anchor Loop Project (TERA 2009a); however, other recent pipeline projects have conducted successful trenchless crossings of major watercourses. To avoid or reduce effects of drilling mud release on riparian habitat, Trans Mountain will continually monitor for sediment release (*i.e.,* turbidity and TSS) throughout the crossing construction period. In the event of a release into a watercourse, Trans Mountain will immediately suspend drilling activities and implement measures outlined in the Drilling Mud Release Contingency Plan to reduce effects of drilling mud release into the watercourse. Any releases would be reported to DFO and AESRD or BC MOE and clean up and monitoring will be carried out until water quality is returned to existing (background) conditions.

Appropriate drill paths will be established and drilling mud pressures and returns monitored to reduce the risk of inadvertent releases of drilling mud during an HDD. The post-construction environmental monitoring program will identify any locations with altered drainage patterns (*e.g.,* ponded water) and remedial work will be conducted, where warranted. Results of the post-construction environmental monitoring from previous projects also indicated the effectiveness of several mitigation measures recommended for the Project in Table 7.2.7-2.

With the implementation of mitigation and reclamation measures, the residual effects of a drilling mud release on riparian habitat are negligible to high in magnitude (depending on the volume of the release and area affected) and reversible in the short to long-term (depending on the pre-existing vegetation community) and the concerns of participants at the Surrey ESA Workshop should be addressed (Table 7.2.7-3, point 1[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – a drilling mud release on land may flow beyond the construction right-of-way, which is also the limit of the Fish and Fish Habitat LSA.
- Duration: immediate to short-term – the event causing an alteration of riparian habitat is the accidental release of drilling mud, the period of which may be less than or equal to two days for small releases or could extend longer.
- Frequency: accidental – the release of drilling mud occurs rarely over the assessment period.
- Reversibility: short to long-term – depending upon the length of time it takes for vegetation to recolonize the area disturbed by mud (*e.g.,* if the release occurs over a small area and if only grasses are affected, they could recover within one growing season; however, if shrubs or trees are affected recovery may extend into the long-term).
- Magnitude: negligible to high – depending upon the location and sensitivity of the receiving environment and the volume of drilling mud released.
- Probability: low – mitigation measures will be implemented during HDD operations to prevent drilling mud release.
- Confidence: high – based on the professional experience of the assessment team.

Contamination of Riparian Habitat from Spills During Construction

In the event of a spill such as a fuel truck rollover, the adverse residual effects would, depending on the volume of the spill and the sensitivity of the receiving environment, range from negligible to high magnitude with potentially long lasting ramifications to riparian vegetation. However, spill contingency and clean up measures would reduce the magnitude and reversibility of the residual effects.

Since spills rarely occur within the construction right-of-way during construction activities, the probability of a significant adverse residual effect is low (Table 7.2-7.3, point 1[d]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – spills resulting in the contamination of riparian habitat may extend beyond the construction right-of-way and, consequently, beyond the Fish and Fish Habitat LSA.
- Duration: immediate – the event causing contamination is a spill, the period of which is less than or equal to two days.
- Frequency: accidental – contamination from spills occurs rarely over the assessment period.
- Reversibility: short to long-term – depending upon the nature and volume of the spill as well as the level of sensitivity of the receiving environment and the pre-existing vegetation community (*e.g.,* shrubs or tress).
- Magnitude: negligible to high – depending on the sensitivity of the receiving environment and volume of the spill.

- Probability: low – based on established mitigation measures to prevent a spill.
- Confidence: moderate – based on the professional experience of the assessment team.

Combined Effects on Riparian Habitat

The components of the Project which may affect the riparian habitat indicator include the construction and operations of the proposed pipeline, temporary facilities (*i.e.,* through construction of access roads), and pump stations (*i.e.,* power lines at Black Pines and Kingsvale), as well as pipeline reactivation activities. No potential effects were identified for riparian habitat resulting from construction and operations activities at the Westridge Marine Terminal or for proposed storage tanks and associated terminals.

The evaluation of the combined effects of the Project on the riparian habitat indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all applicable Project components. TEK participants have reported a steady decline in water quality and fish populations over the past 30 years in the region (*i.e.*, Edmonton to Hinton Segment), which they consider to be due to the cumulative effects of pollution and industrial development. Overall, the Project has the potential to alter riparian habitat as a result of construction and operations activities in and around waterbodies and watercourses, which is considered to have a negative impact balance. Through implementation of industry standard and provincially and federally recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the riparian habitat indicator are considered to be of low magnitude (Table 7.2.7-3, point 1[e]). A summary of the rationale for all of the significance criteria of combined effects on surface water quality is provided below.

- Spatial Boundary: Aquatics RSA – combined effects to riparian habitat may extend beyond the Fish and Fish Habitat LSA in consideration of some activities (*e.g.,* for hydrostatic testing).
- Duration: short-term – the duration of Project activities contributing to combined effects to the riparian habitat indicator vary, but are mostly confined to the construction phase or would not extend beyond a year during the operations phase (*e.g.,* integrity dig).
- Frequency: isolated to occasional – the events causing effects to riparian habitat will primarily occur during the construction phase (*i.e.,* isolated), however, some activities during operations will also contribute to effects to riparian habitat and occur intermittently and sporadically (*i.e.*, occasional).
- Reversibility: medium to long-term – areas in which riparian vegetation is disturbed during construction or operations are expected to be reversed in the medium to long-term, depending on the pre-existing vegetative community (*e.g.*, shrubs or trees).
- Magnitude: low – combined effects to riparian habitat as a result of Project construction and operations are considered to be of low magnitude given the implementation of industry standard and provincially and federally recommended mitigation measures.
- Probability: high – riparian habitat will be affected by some aspects of the Project (*i.e.,* clearing for watercourse crossing construction or at hydrostatic test locations).
- Confidence: high – based on the professional experience of the assessment team.

<u>Fish and Fish Habitat Indicator – Instream Habitat</u>

The following provides the evaluation of significance of potential residual effects on the instream habitat indicator related to construction activities, release of instream drilling mud, contamination from small spills during construction and increased access during operations.

Alteration of Instream Habitat within the ZOI

The components of the Project which affect the instream habitat indicator include the construction and operations of the proposed pipeline, temporary facilities (*e.g.,* through increased access and temporary vehicle crossings), terminals and associated tank facilities, and pipeline reactivation activities (*i.e.,* through hydrostatic testing). There are no effects to instream habitat identified with construction of the Westridge Marine Terminal.

The pipeline corridor selection criteria included reducing the number of watercourse crossings to the extent practical and crossing watercourses perpendicular to the banks. The proposed crossing techniques and mitigation measures have taken into consideration the sensitivity of the watercourses (inclusive of TEK), including habitat characteristics, fish species present, and instream work windows, in addition to the construction schedule, and technical and economic feasibility of each crossing (see Appendix A, Crossing Summary Table, of the Fisheries [Alberta] and Fisheries [British Columbia] Technical Reports of Volume 5C). The introduction of fine sediment to watercourses from instream activities, right-of-way runoff and erosion can have sub-lethal (*e.g.,* irritation of gill tissue) or lethal (*e.g.,* suffocation of developing embryos) effects on fish, and can also cause downstream sediment deposition that alters substrate composition and modifies the availability and suitability of habitat for spawning, overwintering and/or rearing (Anderson *et al.* 1996, Newcombe and MacDonald 1991).

Bank stabilization through the application of native seed mixes with quick germinating cover crops, in addition to enhanced revegetation efforts including geotextiles or biostabilization, will be the preferred methods of stabilizing watercourse banks disturbed as a result of pipeline construction.

The implementation of the proposed mitigation measures, in accordance with the applicable DFO Operation Statement (OPs) and the AESRD codes of practice (COPs), will reduce the potential for serious harm to fish or any permanent alteration to, or destruction of, fish habitat as a result of trenched pipeline crossings and temporary vehicle crossings. Nevertheless, a Section 35 Authorization from DFO will be applied for, and fish habitat compensation/offset will be implemented as defined in the Authorization, should serious harm to fish or any permanent alteration to, or destruction of, fish habitat be expected as a result of construction activities. In the event that serious harm to fish or any permanent alteration to, or destruction of, fish habitat is expected and a fish habitat compensation/offset plan is required, the fish habitat compensation/offset plan will be used to ensure compliance with DFO's Fisheries Protection Policy (DFO 2013a). Post-construction environmental monitoring for the TMX Anchor Loop Project included instream habitat assessments, particularly at fish-bearing watercourses where the harmful alteration, disruption and destruction (HADD) of fish habitat had been authorized by DFO. Results of the 2010 post-construction environmental monitoring (*i.e.*, 2 years after construction) indicated that the mitigation used during construction to mitigate potential effects to instream habitat was effective and all habitats were functioning as intended (TERA 2011a). Many of the same, standard mitigation measures used during construction of the TMX Anchor Loop Project will also be applied to the proposed Project.

The maximum area of instream habitat that may be disturbed by construction of the proposed pipeline is 8.52 ha. Because it will be unknown until closer to the time of construction as to whether a proposed trenchless crossing method will be successful at a given watercourse, this maximum area is based on the assumption that a trenched (*i.e.*, isolated or open cut) crossing method is used at every proposed crossing location and that the area of instream habitat disturbed will be the entire width of the Project Footprint. The actual disturbance to instream habitat is expected to be less, since some watercourses will be crossed using a trenchless method, which, if successful, will not alter instream habitat. The total area of instream habitat in the Aquatics RSA is approximately 60,271.14 ha and the disturbance caused by construction of the pipeline represents 0.01% of the instream habitat within the Aquatics RSA (Table 7.2.7-5). Instream habitat may also be disturbed during the construction of vehicle crossings associated with temporary facilities or power lines, however, these details are currently unknown and the disturbed area is anticipated to be minor.

TABLE 7.2.7-5

PROJECT DISTURBANCE OF INSTREAM FISH HABITAT WITHIN THE AQUATICS RSA

Province	Area of Riparian Habitat in RSA (ha)	Area of Disturbed Riparian Habitat (ha)	% of Riparian Habitat Disturbed
Alberta[1]	17,346.11	0.93	<0.01
British Columbia [2]	42,925.03	7.59	0.02
TOTALS	60,271.14	8.52	0.01

Notes: 1 The Middle North Saskatchewan River watershed is not included because Project instream disturbance in this watershed is located within the City of Edmonton, and the City of Edmonton has been excluded from the quantitative analysis (Section 8.1.5).

2 The Lower Fraser River and Squamish watersheds are not included because Project instream disturbance in these watersheds is located within the LMDA, and the LMDA has been excluded from the quantitative analysis (Section 8.1.5).

The Similkameen watershed is not included because there is no Project instream disturbance in this watershed.

3 Calculations based on footprint disturbances provided in Table 8.1-1 and are approximate.

The residual effects of the Project on instream habitat are expected to be of low magnitude and reversible in the short to medium-term for most watercourse crossings encountered by the Project. In addition, for watercourses where serious harm to fish or any permanent alteration to, or destruction of, fish habitat occurs and a fish habitat compensation/offset plan is required, the mitigation proposed will reduce the magnitude of effects to low (Table 7.2-7.3, point 2[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – alteration of instream habitat may extend beyond the Fish and Fish Habitat LSA for some activities (*e.g.,* for hydrostatic testing).
- Duration: immediate to short-term – the event causing alteration of instream habitat is watercourse crossing construction which can be completed within two days for small watercourses with no water but would take longer where water is present.
- Frequency: isolated – the event causing alteration of instream habitat is confined to the construction phase.
- Reversibility: short to medium-term – any sediments that result in deposition on the substrate of a watercourse are expected to be flushed from the system following the first annual flushing event after construction and, if any fish habitat compensation/offset measures are implemented, they should be implemented during construction and/or within the first year following construction of the watercourse crossing.
- Magnitude: low – based on the effectiveness of the proposed mitigation, the anticipated level of effects of the alteration of instream habitat and the implementation of a compensation/offset plan if serious harm to fish or any permanent alteration to, or destruction of, fish habitat is anticipated.
- Probability: high – some watercourses with documented fish presence will be crossed using trenched (*i.e.,* isolated or open cut) crossing methods.
- Confidence: high – based on a good understanding by the assessment team of trenched crossing methods and associated affects on instream habitat.

Alteration of Instream Habitat from Drilling Mud Release

During HDD crossings, monitoring of drilling fluid volumes and pressure, as well as monitoring of sediment concentrations in the watercourse and on-land frac-outs are expected to help reduce the potential for a drilling mud release to affect instream habitat.

A release of drilling mud into a watercourse could affect instream habitat by increasing suspended sediments and subsequent sediment deposition; however, with the implementation of the Horizontal Directional Drilling/Trenchless Planning and Procedures Management Plan (Appendix C of the Pipeline

EPP of Volume 6B), the residual effects of a drilling mud release on instream habitat are considered low to high, but of low probability.

Information acquired during an HDD feasibility assessment will be used to establish appropriate drill paths, and monitoring of drilling mud pressures and returns will be conducted to reduce the risk of an inadvertent release of drilling mud. This residual effect is considered reversible in the immediate to medium-term, depending on the volume of the release and flow rates of the watercourse (Table 7.2.7-3, point 2[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Fish and Fish Habitat LSA – drilling mud released into surface water may be carried downstream but should settle out within the ZOI.
- Duration: immediate to short-term – the event causing the alteration of instream habitat is the accidental release of drilling mud, the period of which may be less than or equal to two days (immediate) or could extend longer (short-term).
- Frequency: accidental – the release of drilling mud occurs rarely over the assessment period.
- Reversibility: immediate to medium-term – depending on the volume of release and flow rates of the watercourse.
- Magnitude: low to high – depending on the location of the release and quantity of drilling mud released.
- Probability: low – mitigation measures will be implemented during HDD operations to prevent drilling mud release.
- Confidence: high – based on the professional experience of the assessment team.

Contamination of Instream Habitat from Spills During Construction

In the event of a spill such as a fuel truck rollover in or near a stream, the adverse residual effects could, depending on the volume of the spill and the sensitivity of the receiving environment, be of high magnitude with potentially long lasting ramifications to the health of the watercourse. Such an event has the potential to occur during any activities in or near a watercourse (*e.g.,* watercourse crossing construction, hydrostatic testing). Although spill contingency and clean up measures would reduce the magnitude and reversibility of the residual effects, such an incident could be considered of high magnitude due to adverse residual effects if it were to occur in a highly sensitive environment.

Since spills rarely occur within the construction right-of-way during construction activities, and occur even more rarely instream, the probability of a significant adverse residual effect is low (Table 7.2.73, point 2[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatic RSA – spills resulting in the contamination of instream habitat may extend beyond the Footprint which is also the Fish and Fish Habitat LSA.
- Duration: immediate – the event causing contamination is an accidental spill during construction.
- Frequency: accidental – contamination from spills occurs rarely, if at all, during the assessment period.
- Reversibility: short to medium-term – depending on the nature and volume of the spill as well as the level of sensitivity of a particular watercourse to adverse residual effects resulting from contamination.
- Magnitude: low to high – depending on the sensitivity of the receiving environment and the volume of the spill.
- Probability: low – based on established mitigation measures to prevent a spill.
- Confidence: high – based on the professional experience of the assessment team.

Disturbance to Instream Habitat Due to a Potential Increase in Access During Operations

If the Traffic and Access Control Management Plan (Appendix C of Volume 6B) does not completely prevent access to pipeline right-of-way during operations, increased access has the potential to alter instream habitat and this residual effect is considered to have a negative impact balance. However, it is noted that 89% of the proposed pipeline corridor parallels the existing TMPL right-of-way or other linear facilities and, consequently, the concern is limited to the potential for increased access at new rights-of-way and watercourse crossings.

Increased off-road vehicle access (*i.e.*, forded crossings), as a result of pipeline development, could result in disturbances to instream habitat during the operations phase of the pipeline through increased suspended sediment or damage to the watercourse substrate.

Trees and/or shrubs will be planted at locations where new access is created in an attempt to control access during operations. Post-construction environmental monitoring will evaluate the effectiveness of changes to access control measures. With the application of measures outlined in the Traffic and Access Control Management Plan (Appendix C of Volume 6B), the magnitude of the residual effect of increased access will be reduced to low (Table 7.2.7-3, point 2[d]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – increased access to instream habitat may occur outside the Fish and Fish habitat LSA (*e.g.,* as associated with temporary facilities).
- Duration: long-term – the event causing fish mortality or injury is increased access to watercourses which is initiated during construction and extends beyond the first year of the operations phase.
- Frequency: occasional – the events contributing to potential habitat alteration *(e.g.,* recreational off-road vehicles fording streams and causing sediment events) may occur intermittently and sporadically during the operations phase.
- Reversibility: immediate to long-term – although grasses in disturbed areas can be re-established relatively quickly, the regrowth of some plants that are planted as part of the mitigation measures identified in the Traffic and Access Control Management Plan could take more than 10 years to reach their desired size.
- Magnitude: low – with the proposed pipeline corridor adjacent to existing rights-of-way for 89% of its length and the implementation of mitigation measures, the residual effect is considered to be low.
- Probability: low – paralleling the existing TMPL right-of-way and other linear facilities and conditions within the Fish and Fish Habitat LSA will limit new opportunities for recreational off-road vehicle use.
- Confidence: moderate – based on the professional experience of the assessment team.

Fish and Fish Habitat Indicator – Fish Mortality and Injury

The following provides the evaluation of significance of potential residual effects on fish mortality or injury indicator related to construction and operations and maintenance activities, small spills during construction, suspended sediment during instream construction, suspended sediment from an instream drilling mud release, increased access during operations, blockage of fish movements and effects on fish species of concern.

Increased Fish Mortality or Injury Due to Construction and Maintenance Activities

Under non-frozen conditions, fish rescue during isolated watercourse crossing construction is unlikely to result in the mortality or injury of fish. Despite the implementation of industry accepted standard mitigation measures outlined in Table 7.2.7-2 and the Pipeline EPP (Volume 6B) during fish rescues, the likelihood of fish injury or mortality arising from an isolated crossing during winter conditions is considered high (Table 7.2.7-3, point 3[a]). This is because removing fish out of water for even a short period of time during very cold ambient temperatures (*e.g.,* 20^{o}C) has the potential to cause injuries to fish that may contribute to increased mortality. Ice may form on wet netting when it is held out of the water and this could cause injuries to fish and if fish are accidentally held out of the water for more than a few seconds, the potential for freezing temperatures to affect the fish themselves increases. Increased sedimentation from construction activities may also cause behavioural or sub-lethal/lethal effects to fish and is discussed in the following subsection. The magnitude of this potential residual effect is considered to be low with the successful implementation of the recommended mitigation measures and if necessary, regulatory authorization for the destruction of fish (DFO 2009). A summary of the rationale for all of the significance criteria is provided below

- Spatial Boundary: Aquatics RSA – fish mortality or injury may result from watercourse crossing construction activities and fish rescue and from construction of temporary vehicle crossings, which may occur outside the Fish and Fish Habitat LSA.
- Duration: immediate to short-term – the event causing fish mortality or injury is construction of the watercourse crossing which will take less than 1 year but may take more than two days at a given crossing location.
- Frequency: isolated – the event causing fish mortality or injury (*i.e.,* construction of the pipeline) is confined to a specific period.
- Reversibility: medium-term – loss of one or more individuals could affect population scale for several years, or until those individuals can be replaced.
- Magnitude: low – based on the implementation of mitigation measures proven to be effective and with appropriate regulatory authorizations where fish rescues are conducted during cold temperatures.
- Probability: low to high – depending on the construction spread and whether fish salvage will be required during winter conditions.
- Confidence: high – based on the professional experience of the assessment team.

Increased Fish Mortality or Injury from Spills During Construction

Spills accidentally released at watercourse crossings with fish habitat potential during construction and maintenance activities could cause behavioural or sub-lethal/lethal effects on fish within the ZOI. A spill, such as a fuel truck rollover in or near a stream, during construction could cause increased fish mortality or injury and would be considered to have a negative impact balance; however, proper spill contingency and clean up measures would reduce the magnitude and increase the reversibility of the residual effects. Depending on the volume of the spill and the sensitivity of the receiving environment, the adverse residual effects could range from negligible to high magnitude with potentially increased fish mortality or injury.

Since spills rarely occur within the construction right-of-way during construction activities, and occur even more rarely instream, the probability of a significant adverse residual effect is low (Table 7.2.7-3 point 3[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – fish mortality or injury may result from watercourse crossing construction activities which are generally confined to the Fish and Fish Habitat LSA but could extend to the Aquatics RSA in consideration of a spill at hydrostatic test sources for terminals.
- Duration: immediate – the event causing increased fish mortality or injury is a spill, the period of which is less than or equal to two days.
- Frequency: accidental – fish mortality of injury from spills occurs rarely over the assessment period.
- Reversibility: short to long-term – depending upon the nature and volume of the spill as well as the level of sensitivity of the receiving population.
- Magnitude: negligible to high – depending on the sensitivity of the receiving indicators and volume of the spill.

- Probability: low – mitigation measures will be implemented to prevent fish mortality or injury.
- Confidence: high – based on the professional experience of the assessment team.

Increased Fish Mortality or Injury Due to Suspended Sediment During Instream Construction

Pipeline corridor selection criteria included reducing the number of waterbody crossings to the extent practical. An increase in suspended sediment may also occur through hydrostatic testing (*e.g.,* as associated with reactivation of pipeline segments) and installation of temporary vehicle crossings. An evaluation of increased suspended solid concentrations during instream construction is provided in Section 7.2.3 Water Quality and Quantity. Through the selection of appropriate watercourse crossing techniques, vehicle crossing methods and the implementation of surface erosion controls and riparian area revegetation as outlined in Table 7.2.7-2 and in the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C), the potential for adverse effects on aquatic systems along the proposed pipeline corridor due to suspended solids in the water column is reduced.

Suspended sediment released at isolated crossings during instream activities could cause behavioural or sub-lethal/lethal effects on fish within the ZOI. Suspended sediment concentrations will, where warranted, be monitored during instream activities at isolated crossings to confirm that TSS averages remain below the CCME standard of 25 mg/L above baseline (CCME 2007). This is the level, based on 24 hours exposure, when mortalities of the most sensitive life history stage can begin to occur (Newcombe 1994).

There is a level of risk to aquatic resources as a result of high levels of sediment discharge caused by instream construction activities. The Canadian Water Quality Guidelines for the Protection of Aquatic Life (CCME 2002) are often used to ensure aquatic resources are protected during instream activities. These guidelines indicate that a biologically important average increase in TSS concentration over a short-term period (*i.e.*, 24 h) is 25 mg/L above the background level (CCME 2002). DFO (2000) has identified risk levels to protect aquatic resources. The risk levels are determined based on the relationship between increasing suspended sediment concentrations and the level of risk that increasing sediment concentrations can have on fish and fish habitat. DFO (2000) indicates that concentrations <25 mg/L, 25-100 mg/L, 100-200 mg/L, 200-400 mg/L and >400 mg/L have very low, low, moderate, high and unacceptable risk, respectively. Additional background on these risk levels is discussed in Birtwell (1999).

An open cut crossing during flowing conditions is recommended as either the proposed or contingency crossing method for at least one watercourse. Although the specific need (*e.g.,* proposed or contingency crossing method), duration and scheduling of open cut crossing(s) during flowing conditions are still to be confirmed, it is expected that the duration and magnitude of sediment events resulting from an open cut crossing during flowing conditions will be longer and higher, respectively, and this may contribute to serious harm to fish or any permanent alteration to, or destruction of, fish habitat and fish mortality or injury. DFO authorization will be obtained should the destruction of fish and fish habitat be deemed unavoidable. Where this occurs, mitigation and compensation/offset requirements will be confirmed during the permitting stage through discussions with appropriate regulatory authorities.

Minor releases of sediment may be associated with the use of temporary vehicle crossings. Although elevated suspended sediment concentrations may result from instream construction and vehicle crossing use, pulses of suspended solids are generally expected to settle out of the water column within the ZOI in a timeframe measuring from minutes to a few hours.

With the implementation of mitigation measures outlined in Table 7.2.7-2 and the Pipeline EPP (Volume 6B), the likelihood of fish mortality or injury arising from suspended sediment during instream construction ranges from low for an isolated crossing to potentially high for an open cut of a large flowing watercourse crossing (Table 7.2.7-3, point 3[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – some Project activities causing an increase in suspended sediment will occur outside the Fish and Fish Habitat LSA.
- Duration: immediate to short-term – the event causing fish mortality or injury due to suspended sediment is instream construction, the period of which may be less than two days at some watercourse crossings (immediate) or could extend longer for others (short-term), depending on the

size of the watercourse and the nature of the activities (*e.g.*, open cut, vehicle crossing installation, hydrostatic test withdrawal).

- Frequency: isolated – the event causing fish mortality or injury (*e.g.*, Eagle Creek construction of trenched crossings) is confined to a specific period.
- Reversibility: medium-term – loss of one or more individuals could affect population scale for several years, or until those individuals can be replaced.
- Magnitude: low to medium – based on the implementation of mitigation measures proven to be effective, regulatory authorizations and, where warranted, the implementation of fish habitat compensation/offset.
- Probability: low to high – although mitigation measures will be implemented to prevent fish mortality or injury and are anticipated to be effective at most watercourse crossings, in the event of an open cut of a large flowing watercourse, there is potential to exceed CCME guidelines within the ZOI.
- Confidence: high – based on available research literature and the professional experience of the assessment team.

Increased Fish Mortality or Injury Due to Suspended Sediment from Drilling Mud Release

During HDD crossings, monitoring of drilling fluid volumes and pressure, as well as monitoring of sediment concentrations in the watercourse and on-land frac-outs are expected to help reduce the potential for a drilling mud release to affect instream habitat.

A release of drilling mud into a watercourse could affect instream habitat by increasing suspended sediments and sediment deposition. Increased sediment in the water column can increase the probability of fish mortality (see Table 7.2.7-3, point 3[d]); however, with the implementation of the Horizontal Directional Drilling/Trenchless Planning and Procedures Management Plan (Appendix C of the Pipeline EPP of Volume 6B), the residual effects of a drilling mud release on fish mortality or injury are considered low to high but of low probability.

Information acquired during an HDD feasibility assessment will be used to establish appropriate drill paths, and monitoring of drilling mud pressures and returns will be conducted to reduce the risk of an inadvertent release of drilling mud. This residual effect is considered reversible in the immediate to medium-term, depending on the volume of the release and flow rates of the watercourse (Table 7.2.7-3, point 3[d]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Fish and Fish Habitat LSA – drilling mud released into surface water may be carried downstream.
- Duration: immediate – the event causing fish mortality or injury is the accidental release of drilling mud, which is immediate.
- Frequency: accidental – the release of drilling mud occurs rarely over the assessment period.
- Reversibility: immediate to medium-term – depending on the volume of release and flow rates of the watercourse.
- Magnitude: low to high – depending on the location of the release and quantity of drilling mud released.
- Probability: low – mitigation measures will be implemented during HDD operations to prevent drilling mud release.
- Confidence: high – based on the professional experience of the assessment team.

Increased Fish Mortality or Injury Due to a Potential Increase in Access During Operation

If the Traffic and Access Control Management Plan (Appendix C of the Pipeline EPP of Volume 6B) does not prevent access to the pipeline right-of-way during operations phase, increased access has the potential to cause increased fish mortality or injury and this residual effect is considered to have a negative impact balance. Participants at the Kamloops ESA Workshop raised concerns about riparian habitat and the importance of the Project limiting access. Concerns were raised by participants at the Surrey ESA Workshop about the potential spread of invasive species and increased recreational use as a result of increased access. However, it is noted that 89% of the proposed pipeline corridor parallels the existing TMPL right-of-way and other linear facilities and, consequently, the concern is limited to the potential for increased access at new rights-of-way and watercourse crossings. Trees and/or shrubs will be planted where new access is created in an attempt to control access during operations (Appendix C of the Pipeline EPP of Volume 6B).

Increased off-road vehicle access (*i.e.*, forded crossings), as a result of pipeline development, could result in disturbances to instream habitat during the operations phase of the pipeline could potentially lead to fish mortality (*e.g.,* legal and illegal harvest of fish by anglers). Increased potential for fish mortality or injury may also occur if the pipeline increased off-road vehicle fordings through streams, resulting in increased suspended sediment, which could directly affect eggs, embryos or juveniles within the watercourse.

Increased access may contribute to angler overharvest, which has been reported as one of the primary sources of fisheries declines in western Canada (Post *et al.* 2002). Top level predators which may occur in the Fish and Fish Habitat LSA such as walleye, northern pike and Arctic grayling, are particularly vulnerable (Berry 1995, 1998, 1999). Restrictive harvest legislation is implemented in BC to protect sensitive species and minimize the potential for overharvest by anglers (BC MFLNRO 2013a).

In addition to effects on fish and fish habitat during the operations phase, pipeline construction and operations personnel represent an incremental source of anglers within the Aquatics RSA and potential source of angler-caused mortalities. To reduce potential harvest, construction staff will be prohibited from angling within the Fish and Fish Habitat LSA while on, or travelling to and from, the construction site. Nonetheless, some construction personnel may fish during their time off.

Trees and shrubs will be planted as part of the revegetation program at watercourse crossings which will prevent increased access. Post-construction environmental monitoring will evaluate the effectiveness of human access control measures. With the application of measures outlined in the Traffic and Access Control Management Plan, the residual effect of increased access will be reduced to low magnitude (Table 7.2.7-3, point 3[e]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – increased access is limited to the instream habitat within the Fish and Fish Habitat LSA at the location of a watercourse crossing but may be extended to the Aquatics RSA in consideration of temporary facilities.
- Duration: long-term – the event causing fish mortality or injury is increased access to watercourses which is initiated during construction and extends beyond the first year of the operations phase. Access may be limited at some watercourses when riparian vegetation is re-established. The time for this may vary and depending on the pre-existing vegetative community (*e.g.,* shrubs or tress).
- Frequency: occasional – the events contributing to fish mortality or injury (*e.g.,* recreational off-road vehicles fording streams causing sediment events and increased angling) may occur intermittently and sporadically during the operations phase of the pipeline.
- Reversibility: short to long-term – the regrowth of some plants that are planted as part of the mitigation measures identified in the Traffic and Access Management Plan could take more than 10 years to reach their desired size.
- Magnitude: low – with the proposed pipeline corridor adjacent to existing rights-of-way for 89% of its length and the implementation of mitigation measures, the residual effect is considered low.

- Probability: low – paralleling existing rights-of-way and conditions within the Fish and Fish Habitat LSA will limit new opportunities for recreational off-road vehicle use.

- Confidence: moderate – based on the professional experience of the assessment team.

Temporary Blockage of Fish Movements

As a result of construction activities, localized blockage of fish movements may occur for the duration of instream construction. The impact balance of this potential residual effect is considered negative since it could affect the ability of fish species to migrate upstream of downstream of the crossings.

Permanent crossings for vehicles can create barriers to fish passage and contribute to habitat fragmentation for fish communities (Harper and Quigley 2000, Johns and Ernst 2007, Marshall 1996, Park *et al*. 2008, Scrimgeour *et al*. 2003). Although bridges and open bottom arches are able to provide satisfactory fish passage, several investigators have reported fish passage problems are frequently associated with culvert crossings (*e.g.,* corrugated metal pipes) (*e.g.,* 53% in Gibson *et al.* 2005, 57% in Johns and Ernst 2007, 50% in Park *et al*. 2008). These fish passage problems are typically associated with poor design (*e.g.,* undersizing) and/or installation, culvert age, reach slope, debris blockages and increased flow velocity (Harper and Quigley 2000, Johns and Ernst 2007, Marshall 1996, Park *et al.* 2008, Scrimgeour *et al.* 2003).

The mitigation measures outlined in Table 7.2-7.2 and the Pipeline EPP (Volume 6B) will reduce the potential for blockage of fish movements by instream construction and temporary vehicle access used for pipeline construction, power line construction and temporary access roads. The residual effect of the construction of the blockage of fish movements is considered to be reversible in the immediate to short-term and well within environmental standards and, consequently, of low magnitude (Table 7.2-7.3, point 3[f]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – blockage of fish movements may extend immediately upstream and downstream of the construction right-of-way during instream construction and temporary vehicle access along the pipeline corridor; however, blockage of fish movements may also occur at temporary vehicle crossings along temporary access roads and power lines which extend past the Fish and Fish Habitat LSA.

- Duration: immediate to short-term – the event causing blockage of fish movements is Project construction (*i.e.*, instream construction of the pipeline, use of temporary vehicle crossings installed along the pipeline construction right-of-way, temporary access roads and power line construction right-of-way), the period of which is less than 1 year at any given watercourse crossing.

- Frequency: isolated – the event causing blockage of fish movements (*i.e.,* construction of the watercourse crossing and use of temporary vehicle crossings) is confined to a specific period at a given watercourse.

- Reversibility: immediate to short-term – any blockage due to instream watercourse construction would be removed upon completion of construction of a given watercourse crossing, which may take a couple days (*i.e.,* immediate) at some crossings but may take longer at others (*i.e.,* short-term); however, any blockage due to temporary vehicle crossings would be removed upon Project construction completion (*i.e.*, short-term).

- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the potential effects on fish movements.

- Probability: high – the proposed pipeline corridor crosses watercourses for which an isolated crossing is recommended if the water is present at the time of construction and temporary vehicle crossings may be installed along temporary access roads and for power line construction.

- Confidence: high – based on the professional experience of the assessment team.

Effects to Fish Species of Concern

Several fish species of concern (*i.e.*, federally and/or provincially listed) are known to occur within the Aquatics RSA and within specific watercourses crossed by the proposed pipeline corridor. No *SARA*-listed species are known within the Aquatics RSA in Alberta; however, Salish sucker, coastrange sculpin, nooksack dace, green sturgeon and white sturgeon are all *SARA*-listed and may occur within the Aquatics RSA in BC. COSEWIC and provincially listed species within the Aquatics RSA include lake trout, lake sturgeon, sauger, spoonhead sculpin, bull trout, Arctic grayling, Athabasca rainbow trout, and northern redbelly dace in Alberta, mountain sucker, eulachon, chiselmouth, bull trout, sockeye salmon (*Cultus* population) and both coastal and westslope cutthroat trout in BC. Details about the life history, habitat and distribution of these species within the Aquatics RSA can be found in Sections 4.3 and 4.4 of the Fisheries [Alberta] and Sections 4.3 to 4.5 of the Fisheries [British Columbia] Technical Reports of Volume 5C.

Vehicle and pipeline crossing methods have been selected to reduce Project-specific effects in consideration of presence and use by fish species of concern. The proposed pipeline crossing methods for watercourses with identified fish habitat are trenchless, and isolated (*i.e.*, if water is present) or open cut crossings (*i.e.*, if dry or frozen to bottom) as listed in the Watercourse Summary Table (Appendix A of the Fisheries [Alberta] and Fisheries [British Columbia] Technical Reports of Volume 5C).

The residual effect of the construction of the pipeline on fish species of concern is considered to be reversible in the short-term and of low magnitude (Table 7.2-7.3, point 3[g]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – fish species of concern may be affected by an increase in suspended sediment concentrations downstream of watercourse crossings or habitat alteration from trenched (*i.e.,* isolated or open cut) crossing methods.
- Duration: immediate to short-term – the event causing fish species of concern to be affected is instream construction of the pipeline.
- Frequency: isolated – the event causing fish species of concern to be affected (*e.g.,* watercourse crossing construction) is confined to a specific period.
- Reversibility: short-term – the residual effects of pipeline construction on fish species of concern is limited to the construction phase and a short time thereafter until habitat conditions are restored to their original state.
- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the potential effects on fish species of concern.
- Probability: low – construction timing, the proposed crossing methods and implementation of the mitigation outlined in Table 7.2.7-2 should reduce the probability of effects to fish species of concern.
- Confidence: moderate – based on the professional experience of the assessment team.

Combined Effects on Fish Mortality and Injury

The components of the Project which affect the fish mortality or injury indicator include the construction and operations of the proposed pipeline, temporary facilities (*i.e.,* through an increase in access due to access roads), terminals and associated tank facilities and pipeline reactivation activities (*i.e.*, from hydrostatic testing). However, only the residual effects associated with pipeline construction are considered likely to occur and, consequently, are included in the assessment of combined effects.

The evaluation of the combined effects of the Project on the fish mortality or injury indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all applicable Project components. Overall, the construction and operations activities of the Project in waterbodies watercourses have the potential to increase fish mortality or injury through fish rescues during cold temperatures, suspended sediment during open cut of a large flowing watercourse and the temporary blockage of fish movements during isolated watercourse crossings and at temporary vehicle installation for pipeline and power line construction and along temporary access roads. This combined effect is considered to have a negative impact balance. Through implementation of industry standard and provincially and federally recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the fish mortality and injury indicator are considered to be of low to medium magnitude (Table 7.2.7-3, point 3[h]). A summary of the rationale for all of the significance criteria of combined effects on fish mortality and injury is provided below.

- Spatial Boundary: Aquatics RSA – combined effects may extend beyond the Fish and Fish Habitat LSA in consideration of temporary vehicle crossing installations for temporary access roads and power lines.
- Duration: immediate to short-term – the events resulting in combined effects to the fish mortality or injury indicator are confined to the construction phase of the Project (*i.e.*, pipeline and power line construction).
- Frequency: isolated – the event resulting in combined effects to the fish mortality and injury indicator is the construction of the Project.
- Reversibility: medium-term – combined effects may result in the loss of one or more individuals from Project construction and affect population scale for several years, or until those individuals can be replaced.
- Magnitude: low to medium – with the implementation of the mitigation measures, the magnitude of most effects on the fish mortality and injury indicator is expected to be low, though some effects (*e.g.*, increased injury or mortality due to suspended sediment at large flowing watercourses) may be of medium magnitude in view of CCME guidelines.
- Probability: high – increased sedimentation as a result of trenched crossings and vehicle crossings are of high probability and may cause injury to fish.
- Confidence: moderate – based on the professional experience of the assessment team.

Fish and Fish Habitat Indicator – Arctic Grayling (Alberta Indicator Species)

There was general consensus by the participants at the Edmonton ESA Workshop that the inclusion of Arctic grayling as a proposed fish and fish habitat indicator was appropriate since potential effects to Arctic grayling would be representative of effects overall to fish and fish habitat. Arctic grayling are distributed across three watersheds along the Edmonton to Hinton Segment, namely the Pembina, Lower McLeod and Upper McLeod river watersheds (Section 5.0, Table 5.7-1). Based on the existing data and the results of the aquatic assessment, Arctic grayling may be found in seven watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Section 5.0, Table 5.7-6). Arctic grayling are distributed across the Hinton to Hargreaves pipeline reactivation segment which lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. Watercourses supporting Arctic grayling will be affected by pipeline construction activities along the Edmonton to Hinton Segment. In addition, potential water sources for hydrostatic testing activities associated with the Hinton to Hargreaves pipeline reactivation may support this species.

Additional information about Arctic grayling distribution and species presence is provided in the Fisheries (Alberta) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C). Arctic grayling are provincially listed as Sensitive (ASRD 2010) and as a Species of Special Concern under the *Wildlife Act* (AESRD 2012a).

Although some potential effects to Arctic grayling are likely (*e.g.,* alteration of riparian and instream habitat) others are less likely to occur (*e.g.,* injury or mortality of Arctic grayling as a result of increased sedimentation). However, in general, Arctic grayling will be affected by changes to riparian and instream habitat and injury or mortality as a result of construction and operations of the Project. A discussion of the significance of potential effects relating to the indicators of riparian habitat, instream habitat and fish mortality and injury have been previously discussed and are relevant when considering the combined effects on Arctic grayling. The magnitude of the potential combined effects on Arctic grayling is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards (Table 7.2.7-3, point 4[a]). In addition, it is not expected that the Project will conflict with *Alberta's Arctic Grayling Management and Recovery Plan* (Berry 1998). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – the combined effects on Arctic grayling (*i.e.,* loss or alteration of riparian habitat, loss or alteration of instream habitat and mortality or injury) may extend beyond the Fish and Fish Habitat LSA (*e.g.,* through hydrostatic testing).
- Duration: immediate to short-term – the combined effects on Arctic grayling are only expected to occur during pipeline and temporary vehicle crossing construction and hydrostatic testing activities, which will be less than 1 year (*i.e.,* short-term) but less than two days (*i.e.,* immediate) at a given watercourse.
- Frequency: isolated – the combined effects on Arctic grayling are limited to a specific phase (*i.e.,* construction of the Project, including reactivation activities).
- Reversibility: medium to long-term – combined effects on Arctic grayling consider are expected to be reversed in the medium to long-term, depending on the pre-existing vegetative community (*e.g.,* shrubs or trees) and the establishment of effective access control during operations.
- Magnitude: low – with the successful implementation of mitigation measures and regulatory authorizations (as applicable), the combined effects to Arctic grayling are expected to be of low magnitude and are not expected to conflict with *Alberta's Arctic Grayling Management and Recovery Plan*.
- Probability: high – due to the multiple pathways of effects to Arctic grayling (*e.g.,* disturbance to riparian and instream habitat, mortality and injury of fish).
- Confidence: moderate – based on the professional experience of the assessment team.

Fish and Fish Habitat Indicator – Athabasca Rainbow Trout (Alberta Indicator Species)

No issues or concerns of Athabasca rainbow trout as an Alberta indicator species were raised at the Edmonton ESA Workshop or Community Workshops (Section 2.0 in the Fisheries [Alberta] Technical Report). There was general consensus by the participants at the ESA Workshop that the inclusion of Athabasca rainbow trout as a proposed fish and fish habitat indicator was appropriate since potential effects to Athabasca rainbow trout would be representative of effects overall to fish and fish habitat.

Athabasca rainbow trout are distributed across three watersheds along the Edmonton to Hinton Segment, namely Lower McLeod, Upper McLeod and Athabasca river watersheds (Section 5.0, Table 5.7-1). Based on the existing data, historical data and the results of the aquatic assessment, Athabasca rainbow trout may be found in 14 watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Section 5.0, Table 5.7-6). The Athabasca rainbow trout present along the Edmonton to Hinton Segment may or may not include pure strains and may or may not be within the Aquatic RSA. Athabasca rainbow trout are distributed across the Hinton to Hargreaves pipeline reactivation segment which lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. Watercourses supporting Athabasca rainbow trout may be affected by pipeline construction activities along the Edmonton to Hinton Segment. In addition, potential water sources for hydrostatic testing activities associated with the Hinton to Hargreaves pipeline reactivation may support this species.

Although Athabasca rainbow trout are not considered to be a distinct subspecies, COSEWIC guidelines recognize Athabasca rainbow trout populations as a "designatable unit" below the species level (ASRD and ACA 2009). Athabasca rainbow trout is provincially listed as at Risk (ASRD 2010) and In Process under the *Wildlife Act* (AESRD 2012a). Anthropogenic (*i.e.*, logging, road construction) and non-anthropogenic (*i.e.*, flooding) processes impact Athabasca rainbow trout habitat (Rasmussen and Taylor 2009). Loss of headwater instream habitat due to anthropogenic activities is the greatest contributor to combined effects for this indicator species. A provincial management plan has not been developed for this species.

Additional information about Athabasca rainbow trout distribution and species presence is provided in the Fisheries (Alberta) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on Athabasca rainbow trout and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 5[a]). The magnitude of the potential combined effects to Athabasca rainbow trout is expected to be low, with the successful implementation of recommended mitigation strategies. The significance rationale of combined effects on Athabasca rainbow trout is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Bull Trout (Alberta Indicator Species)

There was general consensus by the participants at the Edmonton ESA Workshop that the inclusion of bull trout as a proposed fish and fish habitat indicator was appropriate since potential effects to bull trout would be representative of overall effects to fish and fish habitat.

Bull trout are distributed across four watersheds along the Edmonton to Hinton Segment, namely Pembina, Lower McLeod, Upper McLeod and Athabasca river watersheds (Section 5.0, Table 5.7-1). Based on existing data and the results of the aquatic assessment, bull trout may be found in six watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Section 5.0, Table 5.7-6). Bull trout are distributed across the Hinton to Hargreaves pipeline reactivation segment which lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. Watercourses supporting bull trout may be affected by pipeline construction activities along the Edmonton to Hinton Segment. In addition, potential water sources for hydrostatic testing activities associated with the Hinton to Hargreaves pipeline reactivation may support this species.

Bull trout are listed as considered to be a Species of Special Concern in Alberta (AESRD 2012a) and are listed under COSEWIC as Threatened and a Species of Special Concern depending on the population (COSEWIC 2013). Bull trout are highly receptive to degraded water and habitat conditions from land disturbance (*i.e.*, roads, oil and gas developments) (ASRD 2012, Brewin *et al.* 2001) which makes contamination, loss or alteration of instream and riparian habitat the greatest contributors to combined effects for this species.

Additional information about bull trout distribution and species presence is provided in the Fisheries (Alberta) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on bull trout and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 6[a]). The magnitude of the potential combined effects to bull trout is expected to be low, with the successful implementation of recommended mitigation strategies. In addition, it is not expected that the Project will conflict with the *Bull Trout Conservation Management Plan* (ASRD 2012). Goals of the management plan include sustaining, restoring and developing bull trout habitat (ASRD 2012). The significance rationale of combined effects on bull trout is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Burbot (Alberta Indicator Species)

The inclusion of burbot as an indicator species was suggested at the Edmonton ESA Workshop (Section 2.0 in the Fisheries [Alberta] Technical Report). The assessment team agreed that the burbot was an appropriate indicator since potential effects to burbot would be representative of overall effects to fish and fish habitat.

Burbot are distributed across all eight watersheds along the Edmonton to Hinton Segment (Section 5.0, Table 5.7-1). Based on the existing data and the results of the aquatic assessment, burbot may be found in 10 watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Section 5.0, Table 5.7-6). Burbot are distributed across the Hinton to Hargreaves pipeline reactivation segment which lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. Watercourses supporting burbot will be affected by pipeline construction activities along the Edmonton to Hinton Segment. In addition, potential water sources for hydrostatic testing activities associated with the Edmonton Terminal and Hinton to Hargreaves pipeline reactivation may support this species. Burbot is not listed federally or provincially as a species of conservation concern and there is no provincial management strategy.

Burbot have become more susceptible to natural and anthropogenic habitat disturbance than in the past (Stapanian *et al.* 2010), thus, contamination, loss or alteration of riparian and instream habitat are the greatest contributors to combined effects for this species. Additional information about burbot distribution and species presence is provided in the Fisheries (Alberta) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on burbot and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 7[a]). The magnitude of the potential combined effects on burbot is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. The significance rationale of combined effects on burbot is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Northern Pike (Alberta Indicator Species)

No issues or concerns of northern pike as an Alberta indicator species were raised at the Edmonton ESA or Community Workshops (Section 2.0 in the Fisheries [Alberta] Technical Report). There was general consensus by the participants at the workshops that the inclusion of northern pike as a proposed fish and fish habitat indicator was appropriate since potential effects to northern pike would be representative of overall effects to fish and fish habitat.

Northern pike are distributed across all eight watersheds along the Edmonton to Hinton Segment (Section 5 Table 5.7-1). Based on the existing data and the results of the aquatic assessment, northern pike may be found in 15 watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Section 5.0, Table 5.7-6). Northern pike are distributed across the Hinton to Hargreaves pipeline reactivation segment which lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. Watercourses supporting northern pike will be affected by pipeline construction activities along the Edmonton to Hinton Segment. In addition, potential water sources for hydrostatic testing activities associated with the Edmonton Terminal and Hinton to Hargreaves pipeline reactivation may support this species.

Northern pike rely on weedy areas for their sedentary life and the removal of shoreline weed beds can contribute to population decline (Berry 1999) which makes contamination, loss or alteration of riparian habitat the greatest contributor to combined effects for this species. Northern pike is not listed federally or provincially as a species of conservation concern, however, a management plan is in place (Berry 1999). Additional information about northern pike distribution and species presence is provided in the Fisheries (Alberta) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on northern pike and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 8[a]). The magnitude of the potential combined effects on northern pike is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. In addition, it is not expected to conflict with *Alberta's Northern Pike Management and Recovery Plan* (Berry 1999). Goals of the management and recovery plan include restoring and maintaining northern pike habitat and restoring and maintaining northern pike distribution and diversity. The significance rationale of combined effects on northern pike is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Walleye (Alberta Indicator Species)

No issues or concerns of walleye as an Alberta indicator species were raised at the Edmonton ESA or Community Workshops (Section 2.0 in the Fisheries [Alberta] Technical Report). There was general consensus by the participants at the workshop that the inclusion of walleye as a proposed fish and fish habitat indicator was appropriate since potential effects to walleye would be representative of overall effects to fish and fish habitat.

Walleye are distributed across six watersheds along the Edmonton to Hinton Segment (Section 5.0, Table 5.7-1). Based on the existing data and the results of the aquatic assessment, walleye may be found in four watercourses crossed by the proposed pipeline corridor in the Edmonton to Hinton Segment (Section 5.0, Table 5.7-6). Walleye are distributed across the Hinton to Hargreaves pipeline reactivation segment which lies within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. Watercourses supporting walleye may be affected by pipeline construction activities along the Edmonton to Hinton Segment. In addition, potential water sources for hydrostatic testing activities associated with the Edmonton Terminal and Hinton to Hargreaves pipeline reactivation may support this species.

Walleye is not listed as a species of conservation concern federally or provincially, however, a management and recovery plan is in place (Berry 1995). Walleye are sensitive to anthropogenic habitat changes (*i.e.*, land clearing along streams) (Berry 1995). Walleye rely on shoreline weeds to provide shelter for juveniles and spawning grounds (Berry 1995) which makes contamination, loss or alteration of riparian habitat the greatest contributor to combined effects for this species. Additional information about walleye distribution and species presence is provided in the Fisheries (Alberta) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on walleye and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 9[a]). The magnitude of the potential combined effects to walleye is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. In addition, it is not expected to conflict with *Alberta's Walleye Management and Recovery Plan* (Berry 1995). Goals of the management and recovery plan include, regulating walleye harvest in line with the production capability of walleye populations and recovering walleye populations to their maximum production. The significance rationale of combined effects on walleye is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Bull Trout/Dolly Varden (BC Indicator Species)

There was general consensus by the participants at the ESA Workshops that the inclusion of bull trout/Dolly Varden as a proposed fish and fish habitat indicator was appropriate since potential effects to bull trout/Dolly Varden would be representative of effects overall to fish and fish habitat.

Bull trout/Dolly Varden are distributed across 10 Project watersheds along the proposed pipeline corridor in BC (Section 5.0, Table 5.7-2). Based on the existing data and the results of the fisheries field program, bull trout/Dolly Varden may be found in 45, 17 and 10 fish-bearing watercourses crossed by the proposed pipeline corridor in the Hargreaves to Darfield, Black Pines to Hope and Hope to Burnaby segments, respectively (Section 5.0, Tables 5.7-9, 5.7-13, 5.7-17). Bull trout/Dolly Varden are distributed across the Darfield to Black Pines pipeline reactivation segment which lies within the Lower North Thompson River Watershed of the Fraser Basin in BC where hydrostatic test water may be drawn from. Bull trout/Dolly Varden may be found in watercourses crossed by the proposed power lines associated with the Black Pines and Kingsvale pump stations in the Lower North Thompson River and Lower Nicola and Similkameen river watersheds, and in potential hydrostatic test water sources for the Sumas and Burnaby Terminals in the Chilliwack and Lower Fraser river watersheds.

Bull trout are Blue-listed as a Species of Special Concern (BC Conservation Data Centre [CDC] 2013) and the South Coast population is considered a Species of Special Concern under COSEWIC (2013). No management plans for bull trout/Dolly Varden are in place in BC. Bull trout are susceptible to degraded water and habitat conditions from land disturbance (*i.e.*, roads, oil and gas developments, forest harvesting, mining developments) (ASRD 2012, Brewin et *al.* 2001, Hammond 2004) and obstructions to movement (*i.e.*, culverts) (Hammond 2004) which makes contamination, loss or alteration of instream habitat the greatest contributor to combined effects for the bull trout/Dolly Varden indicator. Additional information about bull trout/Dolly Varden distribution and species presence is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing Atlas (Appendix B), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on bull trout/Dolly Varden and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 10[a]). The magnitude of the potential combined effects to bull trout/Dolly Varden is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. The significance rationale of combined effects on bull trout/Dolly Varden is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Chinook Salmon (BC Indicator Species)

There was general consensus by the participants at the Kamloops and Surrey ESA Workshops that the inclusion of Chinook salmon as a proposed fish and fish habitat indicator was appropriate since potential effects to Chinook salmon would be representative of overall effects to fish and fish habitat.

Chinook salmon are distributed across 10 Project watersheds along the proposed pipeline corridor in BC segments (Section 5.0, Table 5.7-2). Based on the existing data and the results of the fisheries field program, Chinook salmon may be found in 20, 14 and 20 fish-bearing watercourses crossed by the proposed pipeline corridor in the Hargreaves to Darfield, Black Pines to Hope and Hope to Burnaby segments, respectively (Section 5.0, Tables 5.7-9, 5.7-13, 5.7-17). Chinook salmon are distributed across the Darfield to Black Pines pipeline reactivation segment which lies within the Lower North Thompson River Watershed of the Fraser Basin in BC where hydrostatic test water may be withdrawn. Chinook salmon may be found in watercourses crossed by the proposed power lines associated with the Black Pines and Kingsvale pump stations in the Lower North Thompson River and Lower Nicola and Similkameen river watersheds, and in potential hydrostatic test water sources for the Sumas and Burnaby terminals in the Chilliwack and Lower Fraser river watersheds.

Chinook salmon are not listed under COSEWIC or provincially as a species of conservation concern and are susceptible to direct and indirect loss of habitat (COSEWIC 2006b) which makes contamination, loss or alteration of instream and riparian habitat equal contributors to combined effects for this species. There is no provincial management strategy for Chinook salmon. Additional information about Chinook salmon mitigation measures, distribution and species presence is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on Chinook salmon and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 11[a]). The magnitude of the potential combined effects on Chinook salmon is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. The significance rationale of combined effects on Chinook salmon is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Coho Salmon (BC Indicator Species)

There was general consensus by the participants at the Kamloops and Surrey ESA Workshops that the inclusion of coho salmon as a proposed fish and fish habitat indicator was appropriate since potential effects to coho salmon would be representative of overall effects to fish and fish habitat.

Coho salmon are distributed across 11 Project watersheds along the proposed pipeline corridor in BC (Section 5.0, Table 5.7-2). Based on the existing data and the results of the fisheries field program, coho salmon may be found in 53, 16 and 44 fish-bearing watercourses crossed by the proposed pipeline corridor in the Hargreaves to Darfield, Black Pines to Hope and Hope to Burnaby segments, respectively (Section 5.0, Tables 5.7-9, 5.7-13, 5.7-17). Coho salmon are distributed across the Darfield to Black Pines pipeline reactivation segment which lies within the Lower North Thompson River Watershed of the Fraser Basin in BC where hydrostatic test water may be drawn from. Coho salmon may be found in watercourses crossed by the proposed power lines associated with the Black Pines and Kingsvale pump stations in the Lower North Thompson River and Lower Nicola and Similkameen river watersheds, and in potential hydrostatic test water sources for the Sumas and Burnaby terminals in the Chilliwack and Lower Fraser river watersheds.

Coho salmon are not listed federally or provincially as a species of conservation concern. According to TEK participants, coho are more durable than other salmon varieties and are best at adapting to changing conditions. However, the species is susceptible to natural and anthropogenic habitat degradation (COSEWIC 2002a) which makes contamination, loss or alteration of instream and riparian habitat equal contributors to combined effects for this species. There is no management strategy for Chinook salmon in BC. Additional information about coho salmon distribution and species presence is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C). There are no management or recovery plans for coho salmon.

The construction and operations of the Project may result in combined effects on coho salmon and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 12[a]). The magnitude of the potential combined effects to coho salmon is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. The significance rationale of combined effects on coho salmon is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Cutthroat Trout (BC Indicator Species)

There was general consensus by the participants at the Kamloops and Surrey ESA Workshops that the inclusion of cutthroat trout as a proposed fish and fish habitat indicator was appropriate since potential effects to cutthroat trout would be representative of overall effects to fish and fish habitat.

Cutthroat trout are distributed across five Project watersheds along the proposed pipeline corridor in BC and is only found in watersheds in the Black Pines to Hope, Hope to Burnaby and Burnaby to Westridge segments (Section 5.0, Table 5.7-2). Based on the existing data and the results of the fisheries field program, cutthroat trout may be found in 6 and 46 fish-bearing watercourses crossed by the proposed pipeline corridor in the Black Pines to Hope and Hope to Burnaby segments, respectively (Section 5.0, Tables 5.7-13 and 5.7-17). Cutthroat trout may be found in watercourses used as hydrostatic test water sources for the Sumas and Burnaby terminals in the Chilliwack and Lower Fraser river watersheds.

Cutthroat trout are susceptible to anthropogenic habitat manipulation and degradation (*i.e.*, mining, forestry, hydroelectric development) (COSEWIC 2006c) which makes contamination, loss or alteration of instream and riparian habitat equal contributors to combined effects for this species. Westslope cutthroat trout are considered a Species of Special Concern (COSEWIC 2013a) and are Blue-listed (BC CDC 2013). Coastal cutthroat trout is not listed federally or provincially. There are no management plans in place for either cutthroat trout species in BC. Additional information about cutthroat trout distribution and species presence is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on cutthroat trout and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 13[a]). The magnitude of the potential combined effects to cutthroat trout is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. The significance rationale of combined effects on cutthroat trout is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

Fish and Fish Habitat Indicator – Rainbow Trout/Steelhead (BC Indicator Species)

There was general consensus by the participants at the Kamloops and Surrey ESA workshops that the inclusion of rainbow trout/steelhead as a proposed fish and fish habitat indicator was appropriate since potential effects to rainbow trout/steelhead would be representative of overall effects to fish and fish habitat.

Rainbow trout/steelhead are distributed across all 13 Project watersheds along the proposed pipeline corridor in BC (Section 5.0, Table 5.7-2). Based on the existing data and the results of the fisheries field program, rainbow trout/steelhead may be found in 45, 34 and 33 fish-bearing watercourses in the Hargreaves to Darfield, Black Pines to Hope and Hope to Burnaby segments, respectively (Section 5.0 Tables 5.7-9, 5.7-13, 5.7-17). Rainbow trout/steelhead are distributed across the Darfield to Black Pines pipeline reactivation segment which lies within the Lower North Thompson River Watershed of the Fraser Basin in BC where hydrostatic test water may be drawn from. Rainbow trout/steelhead may be found in watercourses crossed by the Black Pines and Kingsvale pump stations in the Lower North Thompson River and Lower Nicola and Similkameen river watersheds and in potential hydrostatic test water sources for the Sumas and Burnaby terminals in the Chilliwack and Lower Fraser river Watersheds.

Rainbow trout are not listed federally or provincially and there are no management plans in place for this species in BC. Rainbow trout are migratory in nature and will swim to new areas should habitat conditions change (Natural Resources Conservation Service 2000). However, contamination, loss or alteration of instream habitat is the greatest contributor to combined effects for this species because the probability of mortality or injury is low. Additional information about rainbow trout/steelhead mitigation measures, distribution and species presence is provided in the Fisheries (British Columbia) Technical Report of Volume 5C, particularly the Watercourse Crossing Summary Table (Appendix A) and the Fish-Bearing atlas (Appendix C), the Pipeline EPP (Volume 6B) and Facilities EPP (Volume 6C).

The construction and operations of the Project may result in combined effects on rainbow trout/steelhead and the significance evaluation of this residual effect is provided in Table 7.2.7-3 (point 14[a]). The magnitude of the potential combined effects to rainbow trout/steelhead is expected to be low, with the successful implementation of recommended mitigation strategies, and within environmental standards. The significance rationale of combined effects on rainbow trout/steelhead is considered to be similar to the rationale for combined effects provided above under the Arctic grayling indicator.

7.2.7.7 Summary

As identified in Table 7.2.7-3, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on fish and fish habitat indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of the Project on fish and fish habitat will be not significant.

7.2.8 Wetland Loss and Alteration

This subsection describes the potential effects of pipeline construction and operations on wetland loss or alteration. The Wetland Evaluation Technical Report of Volume 5C provides further information pertaining to existing wetland function along the proposed pipeline corridor.

7.2.8.1 Assessment Indicators and Measurement Endpoints

The selection of indicators for wetland loss or alteration included: consideration of the filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions and potential issues; feedback from Aboriginal communities, regulatory authorities and stakeholders; available research literature; feedback from participants in the ESA Workshops; public issues raised through the media; and the professional judgment of the assessment team. Initially, the proposed indicators of wetland loss or alteration included wetland function (functional condition) and wetlands of special concern (functional condition). These indicators were discussed during the Edmonton, Kamloops and Surrey ESA Workshops as well as with Aboriginal communities, stakeholders, the public and regulatory authorities. Participants of the workshops did not express any concerns about the proposed indicators of wetland loss or alteration and whether they were appropriate for evaluating the effects of the Project on wetlands. Although some participants did express the wish to see wetlands restored to a functional condition that was better than the current functional condition and emphasised the importance of ephemeral wetlands, no additional wetland indicators were suggested by participants. The ESA Workshops and meetings held with federal, provincial and municipal regulatory authorities did not reveal any site-specific wetland information. Input on the proposed wetland indicators was also sought from AESRD, BC MOE, BC MFLNRO and Environment Canada (Section 3.0); all four agencies were in agreement that the proposed wetland indicators were appropriate and suggested no additional indicators for consideration.

Through discussions with the assessment team for the Vegetation Technical Report (Volume 5C), it was determined that wetlands of special concern would be evaluated within one of the vegetation indicators (*i.e.*, vegetation communities of concern). To reduce assessment duplication of the same indicator, it was decided that wetlands of special concern will be presented in the Wetland Evaluation Technical Report (Volume 5C) but will be addressed within the scope of the vegetation effects assessment in Section 7.2.9 as an indicator (*i.e.*, vegetation communities of concern). Wetland-specific results are presented in the Wetland Evaluation Technical Report of Volume 5C. Therefore, only one indicator (*i.e.*, wetland function) will be assessed in this subsection. These changes were discussed during consultation with Environment Canada and were deemed appropriate with no additional suggestions being made.

The measurement endpoint for the wetland loss or alteration indicator, wetland function, includes quantitative measurements of potential Project effects. Wetland function was evaluated at each wetland encountered during the ground-based field work. The functions of wetlands crossed by the proposed pipeline corridor are reported on the premise that wetlands temporarily disturbed during construction would be revisited in the years following pipeline construction to document the progress of function returning to the wetland ecosystem and to ensure wetlands are on the trajectory of reaching pre-construction (*i.e.*, existing) conditions. Wetland functions documented during the evaluation of existing conditions (*i.e.*, pre-construction) will be compared to wetland functions observed along the reclaimed (*i.e.*, post-construction) construction right-of-way. The results of this comparison will be used to measure the effectiveness and efficiency of mitigation and reclamation measures, and provide support to the determination of loss or "no net loss" of wetland function. Details on each of the wetland functional categories are as follows.

- High Functional Conditions: wetlands that demonstrate many wetland functions expected for their type and class, with little to no anthropogenic disturbance, are high functioning wetlands. These wetlands are performing all expected wetland functions for their type and class (*e.g.*, vegetation and wildlife habitat function, hydrological function as well as water quality and substrate functions). Following construction, these wetlands are likely to recover to their wetland type and class, and no alterations to the existing wetland function qualities provided are anticipated.

- High-Moderate Functional Conditions: wetlands that demonstrate many wetland functions expected for their type and class, with light anthropogenic disturbance, are high-moderate functioning wetlands. These wetlands are mildly disturbed, which reduces the efficacy of the wetland to perform all wetland functions expected for the wetland type and class (*e.g.*, vegetation and wildlife habitat function, hydrological function as well as water quality and substrate functions). Following construction, these wetlands are likely to recover to their wetland type and class, and no alterations to the existing wetland function qualities provided are anticipated.

- Low-Moderate Functional Conditions: wetlands that demonstrate some the wetland functions expected for their type and class, with moderate anthropogenic disturbance are low-moderate functioning wetlands. They are moderately disturbed throughout or have considerable disturbance to the wetland margins and riparian area. The disturbance reduces the efficacy of the wetland to perform wetland functions expected for the wetland type and class (*e.g.*, vegetation and wildlife habitat function, hydrological function as well as water quality and substrate function). Following construction, these wetlands may recover to their wetland type and class. However, the potential for a land use change (*e.g.*, cultivation) following construction may alter the wetland's ability to recover its wetland function qualities, which may impact the recovery trajectory.

- Low Functional Conditions: wetlands that demonstrate limited wetland functions expected for their type and class due to severe anthropogenic disturbance. These wetlands are severely disturbed, which impacts the efficacy of the wetland to perform wetland functions expected for the wetland type and class (*e.g.*, vegetation and wildlife habitat function, hydrological function as well as substrate function). Following construction, these wetlands have unlikely potential to recover to their wetland type and class, which will alter the type of wetland functions that were documented during existing surveys. Alternatively, these wetlands may not recover as functional wetlands (*i.e.*, necessary hydrology, soil and vegetation characteristics).

Table 7.2.8-1 provides a summary of the indicator and measurement endpoint used in the assessment of potential effects on wetlands.

TABLE 7.2.8-1

ASSESSMENT INDICATOR AND MEASUREMENT ENDPOINTS FOR WETLAND LOSS OR ALTERATION

Wetland Indicator	Measurement Endpoint	Rationale for Indicator Selection
Wetland function	• Area (ha) of wetlands (*i.e.*, habitat, hydrology, biogeochemistry) disturbed/contaminated that are of High Functional Condition, High-Moderate Functional Condition, Low-Moderate Functional Condition and Low Functional Condition	The selection of the indicator and measurement endpoint considered NEB *Filing Manual* requirements for the wetland element in Table A-2, experience gained during previous projects with similar conditions and potential issues, feedback from Aboriginal communities, regulatory authorities, and stakeholders, available research literature, and professional judgment of the assessment team. These selections were also supported by participants of the ESA Workshops and by regulatory authorities (*i.e.*, AESRD, BC MOE, BC MFLNRO and Environment Canada). The indicator (*i.e.*, wetland function) complies with the "no net loss" of wetland function requirement of the Federal Policy on Wetland Conservation (Environment Canada 1991).

7.2.8.2 Spatial Boundaries

The spatial boundaries used in the effects assessment of wetlands considered one or more of the following areas:

- a Footprint Study Area (as defined in Section 7.1.3);
- a Wetland LSA; and
- a Wetland RSA.

A Wetland LSA was established to reflect the area in which Project construction and operations activities would most likely affect wetlands. The ZOI likely to be affected by direct disturbance during construction and operations aligns with the Vegetation LSA, where vegetation (*i.e.*, species composition, health and vigour) is one of the primary indicators of wetland function. The spatial boundary of the Wetland LSA for the Project is a 300 m wide band generally from the centre of the proposed pipeline corridor (*i.e.*, 150 m on both sides of the proposed pipeline corridor centre) with site-specific tailoring to extend around larger wetland complexes that are encountered by the proposed pipeline corridor. The 300 m wide band with site-specific modifications, is considered to be a sufficient size along the entire proposed pipeline corridor since the wetlands encountered in Alberta are commonly isolated basins or smaller wetland complexes located within agricultural lands with some forested areas, and those in BC are located within steep mountain valleys or exist as isolated basins or smaller wetland complexes within agricultural lands. The level of existing disturbance or the confining nature of the surrounding landscape is not conducive to a larger LSA boundary.

The spatial boundaries of the Wetland RSA are defined as the area where the direct and indirect influence of other land uses and activities could overlap with Project-specific effects and cause cumulative effects on wetland function. The Wetland RSA aligns in general with the Aquatics RSA where regional hydrology is the overall driver for wetland occurrence and includes all watersheds affected by the Project. The Wetland RSA is shown on Figure 5.8-1.

7.2.8.3 Ecological Context

The 2012 and 2013 helicopter reconnaissances and wetland field surveys confirmed that 638 wetlands (approximately 94.4 km and 570.4 ha) are crossed by the proposed pipeline corridor, comprising approximately 9.6% of the length of the Project. As the exact alignment of the construction right-of-way has not yet been determined, a conservative measurement of wetland lengths was taken from the widest expanse of each wetland within the proposed pipeline corridor. Wetlands crossed include 141 basin marshes, 67 riparian marshes, 4 lacustrine marshes, 7 slope marshes, 2 hummock marshes, 104 flat swamps, 78 riparian swamps, 2 discharge swamps, 6 slope swamps, 45 basin water, 19 riparian water, 13 basin fens, 26 horizontal fens, 13 riparian fens, 2 channel fens, 1 feather fens, 1 slope fen and 1 basin bog. It should be noted that the number of wetlands presented here has been updated following a late season wetland survey conducted in October 2013 along the Edmonton to Hinton Segment after the Environmental Alignment Sheets were finalized for filing. Therefore, some discrepancies maybe noted between the ESA, Wetland Evaluation Technical Report (Volume 5C) and the Environmental Alignment Sheets of Volume 6E. This discrepancy along with the number and classification of wetlands crossed by the proposed pipeline corridor will be updated following supplemental wetland surveys planned for 2014 targeting locations where access was not available in 2012 or 2013.

The proposed pipeline corridor is located within 4 Ecozones and 11 Ecoregions of Canada (Agriculture and Agri-Food Canada 2013, Ecological Stratification Working Group 1995), 7 Wetland Regions of Canada (Government of Canada 1986), 5 Natural Subregions of Alberta (Natural Regions Committee 2006) and 9 Biogeoclimatic Zones of BC (BC MFLNRO 2012a).

Wetlands along the proposed pipeline corridor were initially identified during helicopter overflights and through satellite imagery interpretation using key indicators such as terrain, surficial material (*i.e.*, mineral soils or organic peats), vegetation cover and the presence or absence of surficial hydrology. Wetland classification and delineations were confirmed during the 2012 and 2013 ground-based wetland field surveys. All wetlands that are encountered by the proposed pipeline corridor are identified on the Environmental Alignment Sheets (Volume 6E). Wetlands that were not visited during the 2012 and 2013 field surveys where land access was not available will be visited during the summer 2014 supplemental wetland field surveys (see Section 9.0).

Many of the wetlands crossed by the proposed pipeline corridor are also either crossed by or adjacent to the existing right-of-way, which was installed and has been in operation for 60 years. Generally, once pipelines (or even power lines) are constructed, the land along the right-of-way remains relatively undisturbed. That the proposed pipeline corridor encounters a large number and varied types of wetlands located directly on and adjacent to the existing right-of-way speaks to wetland resiliency and the fact that wetland ecosystems do recover and are able to thrive following the temporary construction disturbance. As well, over the past 60 years, wetland best management practices and mitigation measures have evolved to not only ensure an increased level of awareness to the importance of the preservation of these ecosystems, however, also to ensure an increased level of effort to assist with wetland recovery.

7.2.8.4 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the construction and operations of the proposed pipeline on the wetland indicator are listed in Table 7.2.8-2. These potential interactions are based on the results of the literature review, available research literature, desktop analysis, field work, modelling and TEK, engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

Participating Aboriginal communities (Section 3.0) identified the importance of wetland habitats that are capable of supporting a diverse range of wildlife and vegetation. The health of wetlands along the proposed pipeline corridor as well as the potential for the Project to adversely affect related wildlife, vegetation and water quality elements of the environment through the loss or alteration of wetland habitat were identified concerns of participating Aboriginal communities during the 2012 and 2013 biophysical field studies for the Project (Wetland Evaluation Technical Report of Volume 5C).

A summary of mitigation measures provided in Table 7.2.8-2 was principally developed in accordance with Trans Mountain standards as well as industry, federal and provincial regulatory guidelines including Stepping Back from the Water (AESRD 2012b), Provincial Wetland Restoration/Compensation Guide (AENV 2007) and Wetland Ways (Wetland Stewardship Partnership 2009), as well as learnings from wetland post-construction environmental monitoring for previous pipeline projects (*e.g.,* Enbridge Pipelines Inc. [Enbridge] [TERA 2011b,c,e, 2012b,c,d], Kinder Morgan Canada Inc. [Kinder Morgan] [Critchley and Foote 2009, TERA 2011f,g,h,i, 2012e, 2013d] and NOVA Gas Transmission Ltd. [NOVA

Gas] [TERA 2011j, 2012f]) and peer-reviewed publications on wetland function (Price *et al.* 2005, Ryder *et al.* 2005, Shem *et al.* 1993, Van Dyke *et al.* 1994).

TABLE 7.2.8-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON WETLAND LOSS OR ALTERATION

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Wetland Loss or Alteration Indicator – Wetland Function				
1.1 Loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.*, habitat, hydrology, biogeochemistry)	All	LSA	<u>Habitat</u> • Ensure that all applicable approvals, licenses and permits are in place prior to commencing applicable construction activities [Section 6.0 of EPP]. • Adhere to applicable clearing guidelines for the protection of streams and wetlands provided in the *Forest Practices Code*, Riparian Management Area Guidebook in BC, where riparian management zones (widths) are identified based on stream or wetland class [Section 8.1]. • Follow applicable DFO Operational Statements outlining conditions and measures to avoid serious harm to fish or any permanent alteration to, or destruction of, fish habitat when working in or near a waterbody that has been identified as providing fish habitat [Section 8.7.1 of EPP]. • Fell all timber within the staked construction boundaries during survey line clearing. No fallen or leaning trees will be permitted outside of the staked construction boundaries or into watercourses/wetlands/lakes [Section 6.0]. • Protect vegetation mat from construction disturbance. Any TWS located within the boundary of a wetland must be approved by Trans Mountain's Inspector(s) [Section 7.0]. • Reduce the removal of vegetation in wetlands to the extent practical. Conduct ground level cutting, mowing or mulching or walking-down of wetland vegetation instead of grubbing. The method of removal of wetland vegetation is subject to approval by the Inspector(s) and Resource Specialist [Section 7.0]. • Narrow down the area of disturbance to the extent practical and clearly mark the area to be cleared [Section 7.0]. • Salvage flagged or fenced live trees or shrubs from the banks of wetlands if requested by the Inspector(s) or noted on the Environmental Alignment Sheets. Store salvaged trees and shrubs along the side of the construction right-of-way in a manner such that they do not dry out before replanting during reclamation [Section 7.0]. • Prohibit clearing of extra TWS within the riparian buffer, only the trench and TWS areas will be cleared. Ensure staging areas for watercourse/wetland crossing construction, grade/borrow areas for wetland ramps and spoil storage areas are located a minimum of 10 m from the banks of watercourses/wetland/lake boundaries. This distance may be reduced by the Lead Environmental Inspector and the Inspector(s) where appropriate controls are in place and where no riparian area is present (*e.g.,* cultivated or disturbed lands that abut the watercourse banks or boundaries of the wetland) [Section 8.1]. • Restrict root grubbing in wet areas, where practical, to avoid creation of bog holes [Section 8.1].	• Alteration of wetland habitat function during and following construction and maintenance activities until vegetation is re-established. • Alteration of wetland hydrological function during and following construction and maintenance activities until vegetation is re-established. • Alteration of wetland biogeochemical function during and following construction and maintenance activities until sedimentation is controlled and vegetation is re-established.

TABLE 7.2.8-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.*, habitat, hydrology, biogeochemistry) (cont'd)	All	LSA	• Restrict root grubbing to the area located outside of the vegetated riparian buffer adjacent to watercourses, wetlands and lakes. There will be no grubbing within vegetated buffers adjacent to watercourses, wetland and lakes except along the trench line and, where warranted, at vehicle crossing areas. See additional grubbing measures in Section 8.1 of the Pipeline EPP. • Allow wetlands to recover naturally (*i.e.*, do not seed wetland areas) [Section 8.6.3]. • Spread mulch to a depth of no more than 5 cm along the construction right-of-way in areas classified as treed peatlands [Section 8.6.3]. • Replant salvaged trees/shrubs along the disturbed riparian margins of the wetland as directed by Trans Mountain's Inspector(s) and as identified in the resource-specific mitigation tables for vegetation and wetlands provided in Appendices J and K, respectively [Section 8.7.4]. • See additional wetland measures in the Pipeline EPP. Hydrology • Install berms and/or cross ditches on approach slopes to wetlands, where warranted [Section 7.0]. • Maintain drainage across the construction right-of-way during all phases of construction [Section 7.0]. • Grade away from watercourses and wetlands to reduce the risk of introduction of soil and organic debris. Do not place windrowed or fill material in watercourses or wetlands during grading. Keep wetland soils separate from upland soils [Section 8.2]. • Install sack trench breakers back from the edge of watercourses where the banks consist of organic material to prevent sloughing of backfill into the channel (see Trench Breaker – Watercourse/Wetland Drawing in Appendix R) [Section 8.4]. • Install trench breakers, where warranted, at the edge of perched wetlands to prevent the pipeline trench from acting as a drain (see Trench Breaker – Watercourse/Wetland Drawing in Appendix R) [Section 8.4]. • Do not dewater any wetland during isolated crossing construction [Section 8.7.4]. • Ensure that wetlands are reclaimed to their pre-construction profile. Remove all corduroy and ramps through sloughs or wetlands, in all circumstances [Section 8.4]. • Leave a trench crown during clean-up of peatlands and non-peat wetlands to allow for settlement of backfilled material within the trench [Section 8.6.3]. • Re-establish surface drainage patterns in wetlands/peatlands to as close to the pre-construction contours as practical during reclamation. Leave frequent breaks in the trench crown in any areas identified as peatland to reduce the risk of ponding water and to re-establish drainage connectivity across the wetland [Section 8.6.3]. • Excavate the trench with wide pad, low-ground-pressure equipment or operate standard equipment from mats [Section 8.7.4]. • Store excavated material in a manner that does not interfere with natural drainage patterns. If necessary, haul spoil to a nearby location for storage (*e.g.,* for wet spoil that does not stack well) [Section 8.7.4].	• See above.

TABLE 7.2.8-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.*, habitat, hydrology, biogeochemistry) (cont'd)	All	LSA	• Use geotextile products and porous polypropylene materials in peatland areas and other poor drainage areas to: – increase the load bearing capacity; – prevent mixing of subgrade and fill; and – allow for the passage of water [Section 9.0]. • See additional wetland measures in the Pipeline EPP. Biogeochemistry • Install a temporary sediment barrier (*e.g.,* sediment fences), where warranted, to eliminate the flow of sediment from spoil piles and disturbed areas into nearby waterbodies including wetlands (see Sediment Fence Drawing in Appendix R) [Section 8.7.1]. • Implement the Wet/Thawed Soils Contingency Plan (see Appendix B) during wet/thawed soil conditions when wet or thawed soils are encountered during construction [Section 8.2]. • Avoid rutting and admixing of wetland soils during non-frozen soil conditions. Install appropriate ramps using mats (*e.g.,* swamp mats) or geotextile and spoil ramps [Section 8.7.4]. • Do not dispose of upland woody debris in mineral wetland [Section 8.1]. • Salvage surface material in unsaturated wetlands, giving extra attention to maintaining dormant root stocks for replacement, where feasible. Salvage a maximum of 40 cm of surface soil if the peat is deeper than 40 cm or to the depth of colour change where there is less than 40 cm of surface material. Ensure a minimum of 15 cm of surface and subsoil is stripped if peat is less than 15 cm [Section 8.2]. • Salvage the upper layer of root zone material (maximum of 0.5 m) over the trench area and retain for use in capping the trench following backfilling [Section 8.7.4]. • Use salvaged surface material or trench spoil as a containment/barrier (see Watercourse Crossing – Open Cut Method for Flowing Watercourses Drawing in Appendix R) if deep water is encountered and the trench area warrants isolation. Consider using spoil material from the trench line as a containment barrier where salvaged surface material is primarily composed of organic material and is likely not able to support a berm/barrier. Location to be determined by Inspector(s). Alternate dam devices such as an Aquadam or meter bags may also be used to isolate the trench area. Pump excess water from work area and trench to opposite side of berm or work ramp [Section 8.7.4]. • Pump water into stable and well-vegetated areas. Monitor discharge areas and change the hose discharge location if adequate natural filtration is no longer feasible and sedimentation could occur [Section 8.7.4]. • Backfill the trench with excavated trench spoil. Remove any excess trench spoil to an upland location approved by the appropriate regulatory authorities [Section 8.7.4]. • Backfill peat and mineral soils in the appropriate order such that peat material rather than the underlying mineral soils remain at the surface so that future drainage through the shallow peat material is not impeded [Section 8.7.4]. • Replace any remaining salvaged upper soil (root zone) material over the trench area. Reclaim the wetland to as close as feasible to its pre-construction profile and ensure no permanent trench crown is left following trench crown subsidence [Section 8.7.4].	• See above.

TABLE 7.2.8-2 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.*, habitat, hydrology, biogeochemistry) (cont'd)	All	LSA	• Install temporary erosion and sediment control structures (*e.g.,* sediment fences, coir logs) immediately following the completion of backfilling lands adjacent to water crossings and wetlands where the potential for sedimentation of the watercourse or wetland exists (see Sediment Fence Drawing and Coir/Straw Log Installation Drawing in Appendix R) [Section 8.4]. • Maintain sediment fences in place at (non-peat) wetland boundaries, where warranted, until a vegetation cover has stabilized the adjacent construction areas [Section 7.0]. • See additional measures in the Pipeline EPP. Monitoring • Conduct Wetland Function Post-Construction Environmental Monitoring (PCEM) to review the recovery of wetland function within the construction right-of-way. Operations • Implement mitigation measures provided in table during operations activities within a wetland.	• See above.
1.2 Contamination of wetland function (*i.e.*, habitat, hydrology, biogeochemistry) due to a spill during construction	All	LSA	• Bulk hazardous materials in temporary construction yards or other designated areas except for quantities required for the daily construction activities. Wastes will be stored in temporary construction yards or other designated areas and removed during final clean-up. Fuel, oil or hazardous materials required to be stored on-site will be stored within secondary containment that is to be located greater than 300 m from a watercourse, wetland or lake [Section 7.0]. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are dumped on the ground or into waterbodies. In the event of a spill, implement the Spill Contingency Plan (see Appendix B) [Section 7.0]. • Do not store fuel, oil or hazardous material within 300 m of a watercourse or waterbody [Section 7.0]. • Do not wash equipment or machinery in watercourses, wetlands or lakes. Control wastewater from construction activities, such as equipment washing or cement mixing, to avoid discharge directly into any body of water [Section 7.0].	• Reduction of wetland habitat, hydrological and biogeochemical function in the event of a spill during construction (depending on the volume and type of substance spilled).

Notes: 1 LSA = Wetland LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

Wetlands are complex ecological systems and, consequently, the evaluation of wetlands for the purposes of environmental impact assessments tends to focus on wetland function. The *Federal Policy on Wetland Conservation* (FPWC) commits all federal departments to the goal of "no net loss" of wetland function on federal lands and waters (Environment Canada 1991, Lynch-Stewart 1992, Lynch-Stewart *et al.* 1996).

The objective of the FPWC is to promote conservation of Canada's wetlands to sustain their ecological and socio-economic functions. Several goals have been established by the FPWC to support this objective, including:

- "No net loss" of wetland function on federal lands or projects;
- Enhancement and rehabilitation of wetlands in areas where the continuing loss or degradation of wetlands or their functions have reached critical levels; and
- Recognition of wetland functions in resource planning, management and economic decision-making with regard to all federal programs, policies and activities.

Trans Mountain understands the intent of the objective of the FPWC.

Where feasible, the proposed pipeline corridor has been routed to reduce potential effects on wetlands by implementing a routing decision framework that takes into consideration the following.

- Avoiding wetlands, where feasible.
- Minimizing length traversing environmentally sensitive areas such as protected areas, or areas containing vegetation and wildlife habitat for species with special conservation status.
- Where practical, following existing linear infrastructure (*e.g.,* pipelines, power lines, roads).
- Using the shortest route practical.
- Where avoidance is not technically or economically feasible, implementing construction and reclamation mitigation measures.
- Monitoring wetland function and recovery post-construction.

7.2.8.5 Potential Residual Effects

The potential residual environmental effects on the wetland indicator associated with the construction and operations of the pipeline (Table 7.2.8-2) are:

- loss or alteration of wetland function (*i.e.*, habitat, hydrological, biogeochemical) during and following construction and maintenance activities until vegetation is re-established, grade and natural flow patterns are restored and until sedimentation is controlled; and
- reduction of wetland habitat, hydrological and biogeochemical function in the event of a spill during construction (depending on the volume and type of substance spilled).

7.2.8.6 Significance Evaluation of Potential Residual Effects

A quantitative analysis was undertaken to evaluate the significance of the potential residual environmental effects for the wetland function indicator as these changes over the existing data within the Footprint Study Area were quantifiable. However, where there are no standards, guidelines, objectives or other established and accepted ecological thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method that is based on available research literature, field experience and professional judgment is considered to be the appropriate method for determining the significance of the anticipated residual environmental effects. Consequently, the qualitative assessment of wetland loss or alteration is considered to be the most appropriate method with the evaluation of significance of the potential residual effects relying on the professional judgment of the assessment team.

The quantitative analysis revealed that there are approximately 2,124.5 ha of wetlands located within the Wetland LSA in Alberta and 1,206.2 ha of wetlands are located within the Wetland LSA in BC. Of this, approximately 570.4 ha of wetlands are encountered by the proposed pipeline corridor. It is estimated that the proposed pipeline corridor may disturb approximately 236.2 ha of wetlands with High Functional Condition, 175.3 ha of wetlands with High-Moderate Functional Condition, 28.7 ha of wetlands with Low-Moderate Functional Condition and 0.1 ha of wetlands with Low Functional Condition. Table 7.2.8-3 provides a summary of the area of wetlands disturbed by the proposed pipeline corridor.

TABLE 7.2.8-3

PROJECT DISTURBANCE OF WETLAND FUNCTION WITHIN THE PROPOSED PIPELINE CORRIDOR AND WETLAND LOCAL STUDY AREA

Province	Total Wetland Area (Within Corridor and LSA) (ha)	Area of Wetlands within Corridor (ha)	Proposed Pipeline Corridor (ha)			
			High Functional	High-Moderate Functional	Low-Moderate Functional	Low Functional[1]
Alberta	2,124.5	382.5 ha	176.9 ha	126.2 ha	15.1 ha	0.0 ha
BC	1,206.2	206.9 ha	59.3 ha	49.1 ha	13.6 ha	0.1 ha

Note: 1 Wetlands of Low Functional Condition were not documented during the 2012 and 2013 field program in Alberta. However, wetlands of this functional condition are expected to occur within the proposed pipeline corridor. These values will be updated following the 2014 supplemental surveys.

Table 7.2.8-4 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the proposed pipeline on the wetland indicator. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.8-4

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON WETLAND LOSS OR ALTERATION

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Wetland Loss or Alteration Indicator – Wetland Function									
1(a) Alteration of wetland habitat, hydrological and biogeochemical functions during and following construction and maintenance activities until vegetation is re-established, grade and natural flow patterns are restored and sedimentation is controlled.	Negative	LSA	Short-term	Periodic	Medium to long-term	Low	High	High	Not significant
1(b) Reduction of wetland habitat, hydrological and biogeochemical functions in the event of a spill during construction.	Negative	LSA	Immediate	Accidental	Short to long-term	Low to high	Low	High	Not significant

Notes: 1 LSA = Wetland LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Wetland Loss or Alteration Indicator – Wetland Function

The evaluation of wetland functional condition was used to assess the level of significance of the potential residual effects associated with the proposed pipeline corridor. The functional conditions (*i.e.*, High Function, High-Moderate Function, Low-Moderate Function and Low Function) were determined based on the level of existing disturbance to the wetlands, the type of wetland (*i.e.*, ephemeral, seasonal, semi-permanent) and their capacity to provide certain functions on a landscape level. The evaluation of significance was based on the anticipated level of residual effect the pipeline construction and operations will have on these wetlands based on their pre-construction functional condition. Three components of wetland function (*i.e.*, wetland habitat, hydrological and biogeochemical) were used to help in this analysis.

Many concerns regarding wetlands were brought forth during several of the stakeholder engagement events held for the Project (*e.g.*, Edson, Valemount, Chilliwack and Burnaby Community Workshops) including difficulties in revegetating wetlands (especially bogs), potential recreational use of wetlands already disturbed during other pipeline projects, potential spills into protected areas (*e.g.*, Cheam Lake Wetlands Regional Park) and cumulative effects.

Alteration of Wetland Habitat Function

Pipeline construction and maintenance activities within wetlands will likely result in some disruption of the function of wetlands, and this is considered to have a negative impact balance. Examples of potential adverse environmental effects on wetland habitat function are: potential changes in species composition; stress on plant species; interruption of wildlife movements; and fragmentation of natural habitats.

With proper construction methods and mitigation measures (*i.e.*, profile contours returned and the appropriate protection and use of the seedbank), these adverse effects can be successfully reduced. For example, Zimmerman and Wilkey (1992) monitored wetlands for effects on vegetation for 20 years post-disruption from pipeline construction. Findings of these long-term monitoring programs show that: adjacent natural wetland areas were not altered in type when the proper construction and mitigation measures were carried out (*i.e.*, wetland contours and elevations match those off the construction right-of-way); no non-native plant species invaded natural areas; and the right-of-way increased diversity.

Additional studies on the effects of pipeline construction on wetland vegetation (Shem *et al.* 1993, Van Dyke *et al.* 1994) report the following observations.

- *Wetland community effects*: at most sites, many plants from adjacent natural areas re-establish themselves on the right-of-way. Rights-of-way that have been constructed in a manner that wetland function is not lost (*e.g.,* profile contours returned and the appropriate restoration or maintenance of the seedbank through ensuring equipment arrives on-site clean and kept free of vegetative debris during construction) appear to have little effect on vegetation in the natural areas.

- *Wetland species diversity*: A greater number of wetland plants have been observed on the right-of-way than in the adjacent natural area. Rights-of-way increase the number and types of habitats in wetlands due to the growth of a variety of succession species. Although the impact balance on wetlands resulting from the disturbance created by the pipeline construction is negative (see Table 7.2.8-4), increased biodiversity is viewed positively since the plants that are regenerating on the right-of-way are native species that occur within the natural wetland habitat, and the result is that habitat function is not negatively impacted.

- *Construction and management practices*: Overall, vegetative cover on rights-of-way in wetlands in a variety of control plots (*i.e.*, various wetland types in areas throughout the US) is generally well-established within 1 to 3 years after pipeline construction when mitigation measures included returning wetland contours and elevations to pre-construction conditions. Minor differences in the final right-of-way surface elevation can strongly influence the type of vegetation that re-establishes on the right-of-way. Other examples of construction and management practices that ensure wetland vegetation will re-establish include conducting ground-level cutting, mowing or mulching of wetland vegetation instead of grubbing, directing grading away from wetlands and allowing natural recovery (*i.e.*, not seeding wetlands).

The effects of construction of a pipeline right-of-way on wetland vegetation and bird communities were investigated up to 2 years following construction by Santillo (1993). Results showed that at 2 years post-construction, wetlands were dominated by native hydrophytic graminoids. Also, in wetlands with no standing water, plant community composition and structure were found to be similar at the end of 2 years post-construction to what was observed pre-construction. Finally, results also showed that no new bird species were introduced as a result of the different habitat provided by the right-of-way after pipeline construction was conducted using appropriate mitigation measures (*e.g.,* re-establishing pre-construction contours within wetland boundary to ensure cross right-of-way drainage) that ensured seedbanks were restored on the construction right-of-way.

Increased plant diversity is discussed here as a finding of research presented in peer-reviewed available research literature (Santillo 1993, Shem *et al.* 1993, Van Dyke *et al.* 1994, Zimmerman and Wilkey 1992). The conclusion of the research was that although there was increased native plant diversity as a result of pipeline construction, the overall habitat function of the wetlands was not negatively impacted.

Increased biodiversity is viewed positively since the plants that are regenerating on the right-of-way are native wetland species, therefore, wetland habitat is not substantially altered. By opening up the canopy, plant species that generally cannot grow beneath a tree or shrub overstory will return to begin the plant succession stages and additional species will begin to inhabit the area. This increase in biodiversity may occur along the proposed pipeline corridor since disturbed peatlands have tree/shrub cover removed during construction. Initially, wetlands that were previously dominated by woody vegetation recover as sedge-dominant marshes due to an increased moisture regime as a result of decreased rates of evapotranspiration.

Salvaging of soils during construction removes microtopography features (*i.e.*, hummocks and hollows) that provide important microclimates. Loss of the habitat variation provided by microtopography features can slow regeneration of wetland vegetation and habitat (Lee and Boutin 2006). Restoration of microtopography features and microclimate variation following construction (*e.g.,* natural recovery in wetlands) accelerates plant community development and re-establishment (Belyea 1996, Kellner and Halldin 2002, Malmar and Wallén 1999, Miller 2011).

Past construction projects in similar ecoregions have successfully reduced effects on wetlands. Post-construction environmental monitoring of wetland function (TERA 2011b,c,e, 2012b,c,d) at wetlands along recent large pipeline projects on agricultural lands have shown that mitigation measures implemented during construction (*e.g.,* profile reconstruction, allowing natural regeneration) can be successful; wetlands have proven to be resilient. In addition, the absence of environmental issues pertaining to wetland health and function restoration has been observed and documented in As-built Environmental Reports for the first, second and third-year Post-Construction Environmental Monitoring (PCEM) reports for numerous past pipeline projects (Interprovincial Pipe Line [IPL] 1995, Enbridge 2000, 2002, TERA Environmental Consultants [Alta] Ltd. 1995, 1996, 2000, 2001a,b, TERA 2002, 2003, 2004, 2009c, 2011b,c,e, 2012b,c,d). The TMX Anchor Loop Project (Critchley and Foote 2009, TERA 2011f,g,h,i 2012e, 2013d) is located within similar terrain as the proposed pipeline corridor; currently TERA is entering into the final year of post-construction environmental monitoring and has documented the successful return of wetland habitat function within 2 to 3 years for the temporarily disturbed marsh, swamp, fen, bog and shallow open water wetlands. By utilising the proven and effective mitigation measures from past projects, it is anticipated that approximately 236.2 ha of High Functional, 175.3 ha of High-Moderate, 28.7 ha of Low-Moderate and 0.1 ha of Low Functional wetland function (*i.e.*, habitat, hydrological and biogeochemical) within the proposed pipeline corridor will be effectively reclaimed within the medium to long-term.

Mitigation measures will be employed to reduce residual effects on wetlands, depending on site-specific conditions and requirements (Table 7.2.8-2 and the Pipeline EPP of Volume 6B). With the implementation of the proposed mitigation measures, the potential alteration of wetland habitat function is considered to be reversible in the medium to long-term for wetlands depending on the pre-construction vegetative cover, and of low magnitude.

Alteration of Wetland Hydrological Function

Pipeline installation or maintenance may cause potential changes to the hydrologic flow (*i.e.*, surface or groundwater flow) of a wetland by diverting water away from the wetland and/or impeding natural flow through the wetland. Excessive water diversion will result in an unnatural decrease of water flow within the wetland while flow impedance (*i.e.*, inadequate drainage) results in a more saturated wetland habitat.

Each of these alterations is an interruption to the natural hydrologic regime and is considered to have a negative impact balance. The vertical and horizontal water movements in wetlands are readily disrupted by any berm-like structure. For example, linear disturbances, such as pipelines and roads, can impound water on the upstream side of a wetland resulting in drying downstream and flooding upstream. Drying on the downslope face in treed wetlands (*i.e.*, treed bogs and fens) can increase tree productivity, water demand and evapotranspiration, which facilitates further drying (Baisley 2012, Miller *et al. in prep.*). In mineral wetlands, this type of disturbance (*i.e.*, drying downstream) may also result in increases in productivity of drought tolerant wetland plant species (*e.g.,* grasses, some sedges and rushes) and water demand, which, similar to treed wetlands, can lead to further drying. The compounded drying can result in permanent alteration of peatland and mineral wetland hydrologic regime, overall wetland function and potentially ecosystem type (*e.g.,* treed wetland to forest or marsh to wet meadow or moist grassland) (Baisley 2012, Miller *et al. in prep.,* Sherwood 2012). On the upstream side, increased saturation from impounded water can result in the loss of trees and other woody vegetation, while allowing for the establishment of emergent vegetation in peatlands (Miller 2011) whereas in seasonal mineral wetlands, increased inundation may result in the decrease of emergent vegetation, the increase in aquatic vegetation and open water characteristics. Prolonged impoundment may potentially convert a treed wetland to an open water or marsh wetland and a more seasonal mineral wetland into a more permanent open water wetland.

The hydraulic conductivity of the wetland's substrate can also be affected by salvaging, compacting or mixing of the soil structure. For example, salvaging of the acrotelm (*i.e.*, the unsaturated portion of the peat profile near the surface) during pipeline construction affects water storage capacity, evaporative losses as well as soil processes (*e.g.,* carbon storage) (Price *et al.* 2003). Pore structure is impacted through subsidence and compression when peat is drained, which affects water storage capacity and hydraulic conductivity (Price *et al.* 2003). Overlaying woody mulch on replaced peat following pipeline construction can increase the relative humidity on the peat surface and decrease evaporative loss thereby reducing the hydrologic impact (Groeneveld and Rochefort 2005, Price *et al.* 2003). However, lessons learned from post-construction environmental monitoring programs have shown that the thickness of mulch can have affect vegetation regrowth if placed too thickly. In mineral wetlands, improper handling (*i.e.*, admixing, salvaged material drying) of salvaged mineral soil and wetland substrate can result in loss of salvaged material through wind erosion (*i.e.*, drying of material while stockpiled). Improper replacement of bottom soils can affect the permeability of the material (*i.e.*, permeable substrate becoming impermeable) as the result of admixing and compaction. These issues can affect a wetland's ability to retain and slowly release flood waters to the groundwater, increase evaporative losses of stored water and limit a wetland's storage capacity (*i.e.*, volume of water a wetland can retain). Storing salvaged material separately (*i.e.*, mineral soil separate from wetland substrate) and maintaining the moisture content can mitigate the effect of wind erosion while replacing salvaged material in the correct order (*i.e.*, mineral soil followed by wetland substrate) following construction can help to maintain bottom soil permeability, therefore, maintaining a wetland's hydraulic conductivity capability.

Among the most important considerations for limiting disturbances to hydrological function are assuring that the restoration of pre-construction elevations and contours are achieved (Gartman 1991), and that there will be no unnatural impedance to flow. Short-term disturbances to wetlands are expected during pipeline construction. Some alteration of hydrological function in wetlands can be expected during trenching, however, the late summer/fall/winter construction schedule in certain areas will reduce potential hydrologic changes since water flow is likely to be diminishing from peak levels. Surface materials at shallow depth (*i.e.*, the mineral soil) should be salvaged and stored separately from other material and sequentially replaced. This will reduce potential changes in the hydrological function of wetlands. If the construction right-of-way in the wetland is restored to its pre-construction profile and proper hydrologic throughflow is ensured by replacement of salvaged wetland substrates/upper soils, long-term effects on wetland hydrological function are not expected. Post-construction environmental monitoring of wetland hydrological function (TERA 2011f,g,h,i 2012e, 2013d) at wetlands along the TMX Anchor Loop Project have shown that mitigation measures implemented during construction (*e.g.,* profile reconstruction) can be successful in returning surface water to pre-construction levels. Seedbank moisture regime recovery (*i.e.*, vegetation growth due to moisture), however, has proven to occur more slowly since surface material moisture levels are regulated either from vegetation removal (resulting in a wetter moisture regime than previous) or the drier conditions commonly present at wetland margins.

Standard pipeline construction and operational activities are designed to avoid circumstances that result in diversion and/or natural flow impedance of water in wetlands. With the implementation of the proposed mitigation measures, the residual effect of pipeline construction and maintenance activities on wetland hydrology is considered to be reversible in the medium to long-term and of low magnitude.

Alteration of Wetland Biogeochemical Function

Changes in wetland hydrologic regime can directly and indirectly affect wetland biogeochemical function. Directly, hydrologic regime can affect soil processes, nutrient availability and water chemistry. For example, soil decomposition rates are controlled by microbial respiration, which is affected by temperature and oxygen availability. Microbes preferentially use oxygen, however, under anaerobic, saturated conditions, the rate and type of respiration is altered (McLatchey and Reddy 1998). Additionally, the heat capacity of saturated soils is higher than that of dry soils. Therefore, decomposition rates are maintained by hydrologic regime through saturated conditions.

Impounding water flow due to linear disturbance can also directly impact wetland biogeochemistry. Fen peatlands receive nutrient inputs primarily from surface and groundwater sources. By impeding water flow, nutrient delivery to downstream parts of the wetland is limited. However, recontouring and/or installing trench crown breaks may alleviate some of this nutrient stress.

Activity in or near wetlands during pipeline construction may result in an increased sediment supply and turbidity of surface waters (particularly in mineral wetlands), thereby, affecting biogeochemical function of the wetland. However, given the implementation of sedimentation control mitigation measures (*i.e.*, sediment fencing), the likelihood of alteration in this manner is reduced.

Indirectly, hydrologic regime can impact biogeochemical function by altering wetland habitat function. For example, decreases in water table position can increase tree productivity rates, which could decrease the quality of litter deposited to soil to increase nutrient turnover-times. This can change understory community composition due to nutrient and light limitations, soil processes (*e.g.,* decomposition rates), as well as further stimulating changes in wetland hydrologic regime through increased transpiration and interception by root systems (Baisley 2012, Kotowska 2012, Laiho *et al.* 2003).

Due to historical peat accumulation, peatlands represent a large reservoir of soil carbon and are estimated to store approximately 30% of the world's soil carbon pool and about 85% of North America's soil carbon (Bridgeham *et al.* 2006, Zoltai and Martikainen 1996). Differences in peatland microtopography (*i.e.*, hummocks versus hollows) help maintain wetland biogeochemical function, particularly carbon cycling (Belyea 1996, Benscoter *et al.* 2011, Malmar and Wallén 1999, Rydin *et al.* 2006). Removing the microtopographical variation within these wetlands through construction and compaction removes the important role they have within ecosystem function (Lee and Boutin 2006, Turcheneck 1990). However, this effect can be reduced by narrowing the construction right-of-way through wetlands and allowing for natural recovery.

Mitigation measures employed during construction and maintenance activities will reduce the residual effect. Consequently, the residual effect of pipeline construction and maintenance activities on wetland biogeochemistry is considered to be reversible in the medium to long-term and is of low magnitude.

A summary of the rationale for all of the significance criteria for all three components of wetland function (*i.e.*, habitat, hydrological and biogeochemical) is provided below (Table 7.2.8-4, point 1[a]).

- Spatial Boundary: Wetland LSA - alteration of habitat (*e.g.,* changes in vegetation species composition, stress on plant species, interruption of wildlife movements and fragmentation of natural habitats), hydrological (*e.g.,* changes in water level, impeded drainage) and biogeochemical function (*e.g.,* water quality, nutrient uptake) resulting from pipeline construction or maintenance activities may extend beyond the construction right-of-way.
- Duration: short-term – the events causing alteration of habitat, hydrological and biogeochemical function are construction of the pipeline and maintenance activities, the latter of which will be completed within any 1 year during the operations phase.
- Frequency: periodic - the events causing alteration of habitat, hydrological and biogeochemical function (*i.e.*, construction of the pipeline and maintenance activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: medium to long-term – depending on the growth time of wetland species (medium-term) found along the proposed pipeline corridor, the time required to reclaim pre-construction elevation and contours (medium-term) and the time for biogeochemical processes to be reclaimed (medium to long-term), the reversibility of the residual effect may take longer than 1 year with the possibility of being greater than 10 years.
- Magnitude: low – based on the proposed mitigation measures (*i.e.*, substrate being restored to pre-construction profile and allowing natural regeneration in wetlands) and the post-construction environmental monitoring literature demonstrates that wetlands are resilient provided habitat function is not permanently altered. If permanent loss or alteration of wetland habitat function is identified upon completion of the Wetland Function PCEM Program, Trans Mountain will consult with Environment

Canada regarding potential remedial or compensatory measures to offset functional loss. However, permanent loss or alteration of wetland function is not anticipated at wetlands crossed by the proposed pipeline construction right-of-way since pipeline construction through wetlands is considered a temporary disturbance and experience indicates that residual effects on wetland function can be mitigated. Reductions in wetland area as a result of the installation of power line structures, however, may be considered a loss but not necessarily a loss of function due to the size of the structures. This potential loss of wetland area will be discussed with Environment Canada.

- Probability: high – the proposed pipeline corridor crosses a number of wetlands and disturbances within these wetlands will likely occur during pipeline construction and site-specific maintenance activities.
- Confidence: high – based on available research literature, results of mitigation measures and post-construction environmental monitoring programs of past pipeline projects and the professional experience of the assessment team.

Effects on Wetlands from Spills During Construction

In the unlikely event of a fuel spill from equipment or a fuel truck near a wetland during construction, infiltration of fuel into surficial deposits and surface water is possible, and the effects would be considered to have a negative impact balance. The implementation of prevention measures (Table 7.2.8-2 and Pipeline EPP of Volume 6B) is expected to mitigate small spills in wetlands. Spill mitigation is expected to result in some loss or disturbance of soil and vegetation. With the implementation of mitigation efforts, the effects of small spills on wetland function (*i.e.*, habitat, hydrological and biogeochemical) are considered to be reduced to low to high magnitude and reversible in the short to long-term (Table 7.2.8-4, point 1[b]).

- Spatial Boundary: Wetland LSA – alteration of wetland function (*i.e.*, habitat, hydrologic and biogeochemical) resulting from a spill during pipeline construction or maintenance activities may extend beyond the construction right-of-way.
- Duration: immediate – the event causing reduction of wetland function is a spill during construction, the period of which is less than or equal to two days.
- Frequency: accidental – contamination of wetlands from spills occurs rarely over the assessment period.
- Reversibility: short to long-term – depending on the volume and area affected by the spill.
- Magnitude: low to high – for potential reduction of wetland habitat, hydrological and biogeochemical functions.
- Probability: low – spills are unlikely to occur within wetlands.
- Confidence: high – based on available research literature, results of mitigation measures and post-construction environmental monitoring programs of past pipeline projects and the professional experience of the assessment team.

7.2.8.7 Summary

As identified in Table 7.2.8-4, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the wetland indicator of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline construction and operations on wetland loss or alteration will be not significant.

7.2.9 Vegetation

The NEB *Filing Manual* provides regulatory guidance for the assessment of vegetation resources where disturbance is expected to occur in previously undeveloped areas. Vegetation resources, including Species at Risk and Species of Special Status as defined by the NEB *Filing Manual*, may be affected by construction and operations activities associated with the Project. The scope and methods required to adequately assess vegetation resources were determined with the guidance of the NEB *Filing Manual*, in conjunction with published rare plant survey recommendations and guidelines (Alberta Native Plant Council [ANPC] 2012, Penny and Klinkenberg 2012).

The Vegetation Technical Report of Volume 5C provides further information pertaining to existing vegetation conditions along the proposed pipeline corridor.

7.2.9.1 Assessment Indicators and Measurement Endpoints

The selection of indicators for vegetation included: consideration of the filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues; feedback from Aboriginal communities, regulatory authorities and stakeholders; feedback from participants in the ESA Workshops; public issues raised through the media; and the professional judgment of the assessment team. A list of the proposed indicators for vegetation was discussed during the Edmonton, Kamloops and Surrey ESA Workshops. There was general consensus by the participants of the workshops that the proposed indicators were appropriate for evaluating the effects of the Project on vegetation.

The vegetation indicators chosen for the Project include:

- vegetation communities of concern;
- plant and lichen species of concern; and
- presence of infestations of Noxious, Provincial weed species and presence of other invasive non-native species identified as a concern.

See Table 7.2.9-1 for the list of vegetation indicators, their measurement endpoints and the rationale for inclusion.

The vegetation communities of concern indicator addresses rare ecological communities as identified by the Alberta Conservation Information Management System (ACIMS), the BC Identified Wildlife Management Strategy and the BC CDC, as well as the communities identified as the most affected by the Project (as determined through Terrestrial Ecosystem Mapping [TEM]). In addition this indicator addresses vegetation communities identified as of concern during consultation, specifically grassland communities within the Bunchgrass (BG) Biogeoclimatic (BGC) Zone. This indicator addresses the NEB *Filing Manual* requirement to consider avoidance of sensitive or rare communities.

Grassland communities in the Kamloops region and old growth forests were suggested as vegetation communities of concern. Upon consideration by the assessment team, all grassland communities in the Kamloops region were adopted as measurement endpoints for the vegetation communities of concern indicator. Old growth forests were determined to be better assessed at other scales and are further discussed in Section 7.2.9.4.

Native vegetation was not initially included as a vegetation community of concern because it is a very coarse measurement that combines many different types of vegetation communities. Additionally, taking each distinct vegetation community through the assessment process is not possible and there was concern in the ESA and Community Workshops that all native vegetation may be important for genetic diversity, habitat for rare plant species and habitat for traditionally used plants. Areas of native vegetation are also raised as a concern in numerous regional management plans (Alberta Energy and Utilities Board 2002, AENV 2003a, Fiera Biological Consulting 2009, Henderson 2011, Maslovat 2009). Therefore, native vegetation was included under the vegetation communities of concern indicator. In addition, the most affected vegetation communities are assessed separately.

Vegetation communities most affected by the proposed pipeline corridor is a measure of specific native vegetation communities which will have a greater areal disturbance as a result of the effects of construction and operations compared to other native vegetation communities in the Vegetation RSA. Vegetation communities most affected was chosen as a measurement endpoint rather than communities of limited distribution (*i.e.,* those communities which occur least frequently in the Vegetation RSA) due to the length of the proposed pipeline corridor and the diversity of habitats encountered by the Vegetation RSA.

The plant and lichen species of concern indicator addresses rare plant and lichen species as identified by the *Species at Risk Act*, COSEWIC, the Alberta *Wildlife Act*, ACIMS, the BC Identified Wildlife Management Strategy and the BC CDC. This addresses the NEB *Filing Manual* requirement to determine effects related to plant species at risk or of special status.

The third vegetation indicator addresses infestations of Noxious weeds, Provincial weed species and other invasive non-native species identified as a concern. Participants in the ESA Workshops also raised concern about invasive species that are not provincially listed as weeds (*e.g.,* crested wheatgrass). The assessment team decided to modify the weed indicator to include other non-native species discussed in consultation. This indicator will inform efforts to address the NEB *Filing Manual* requirements to consider weed control measures and seed mixes.

Input on the proposed vegetation indicators was also sought from Environment Canada and Canadian Wildlife Services (CWS) (Section 3.0); both agencies were in agreement that the proposed vegetation indicators were appropriate and suggested no additional indicators for consideration.

TABLE 7.2.9-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR VEGETATION

Vegetation Indicators	Measurement Endpoints	Rationale for Indicator Selection
Vegetation communities of concern	• ha of native vegetation altered on the Footprint, in the Vegetation LSA and RSA • % potential alteration of the most affected vegetation communities (variant and/or ecosite) on the Footprint, in Vegetation LSA and RSA • ha of grassland communities within the Bunchgrass BGC altered on the Footprint, in the Vegetation LSA and RSA • Abundance and distribution of rare ecological communities altered on the Footprint, in the Vegetation LSA and RSA	The selection of indicators and measurement endpoints considered NEB *Filing Manual* requirements for the vegetation element, addressed concerns raised by participants of the ESA Workshops and was informed by regulatory authorities (*i.e.*, Environment Canada and CWS). All grassland communities in the Kamloops region were adopted as measurement endpoints for the vegetation communities of concern assessment indicator after concerns were raised during the ESA Workshops in the region. Native vegetation is important for genetic diversity, habitat for rare plant species and habitat for traditionally used plants, therefore, native vegetation was added as a community of concern.
Plant and lichen species of concern	• Abundance and distribution of observed rare plant and lichen populations on the Footprint	The selection of indicators and measurement endpoints considered NEB *Filing Manual* requirements for the vegetation element, addressed concerns raised by participants of the ESA Workshops and was informed by regulatory authorities (*i.e.*, Environment Canada and Canada Wildlife Service [CWS]).
Presence of infestations of Noxious, Provincial weed species and presence of other invasive non-native species identified as a concern	• Qualitative assessment of weed issues including weed species identified as being of concern in the vicinity of the Project, as well as the density and distribution of observed weeds and invasive non-native species	The selection of indicators and measurement endpoints considered NEB *Filing Manual* requirements for the vegetation element, addressed concerns raised by participants of the ESA Workshops and was informed by regulatory authorities (*i.e.*, Environment Canada and CWS). Participants in the ESA engagement workshops raised concerns about invasive species that are not provincially listed as weeds. The assessment team decided to modify the weed indicator to include other non-native invasive species discussed in consultation.

7.2.9.2 Spatial Boundaries

The spatial boundaries used in the effects assessment of vegetation considered one or more of the following areas:

- a Footprint Study Area (as defined in Section 7.1.3);
- a Vegetation LSA; and
- a Vegetation RSA.

The Vegetation LSA represents the ZOI in which vegetation resources are most likely to be affected by the construction and operations of the Project. Key considerations used to establish the spatial boundaries of the Vegetation LSA for the Project include the distance that edge effects are expected to extend from a disturbed area (*i.e.*, that impact plant species and vegetation communities). The spatial extent of changes in vegetation composition may be affected by a number of factors. In one study, increased light was shown to allow the invasion of shade-intolerant vegetation up to 30 m from the edge of the disturbance (Ranney *et al*. 1981). Some tree species exhibit increased growth and regeneration within 30-60 m of clear-cut edges; however, tree mortality can also increase (Bannerman 1998). Within an old growth Douglas-fir forest, air temperature and humidity were generally found to be influenced to a depth of 120-180 m in areas adjacent to a clear-cut edge, while soil temperature and moisture were influenced from 60-120 m from the edge (Chen *et al*. 1993). While some roadway effects are not applicable to pipeline construction, equipment traffic along the construction right-of-way, the use of temporary access and the removal of vegetation may result in some comparable effects. Forman *et al*. (2003) found that the greatest changes to microclimate and dust levels occurred within the first 30-50 m from road edges, while the greatest changes in hydrological function, salinity and nitrogen levels could extend 100-200 m from the disturbed area. Based on the above concepts, the Vegetation LSA generally consists of a 300 m wide band from the centre of the pipeline corridor (*e.g.*, 150 m on both sides of the centre of the proposed pipeline corridor) was established to assess Project-related effects to vegetation resources.

The Vegetation RSA represents the area where the direct and indirect influence of other land uses and activities could interact with Project-specific effects and may cause cumulative effects on vegetation. Key considerations used to establish the spatial boundaries of the Vegetation RSA for the Project included the separation distance typically used to distinguish one rare plant population from another; the dispersal of non-native, invasive species to or from the Project footprint; provision of baseline data and mapping sufficient to support accurate assessment of wildlife habitat resources within the respective LSA of that biophysical component; and the physical footprint of the Project within a regional landscape context.

An Element Occurrence (EO) is the area of land or water in which a rare species or rare ecological community of conservation interest is or was present (BC MOE 2013b, NatureServe 2002). EOs generally refer to a local population or metapopulation (NatureServe 2002). Although there are many factors which may be taken into account in determining individual EOs, the default minimum separation distance for plant species EOs is 1 km (NatureServe 2002, 2004).

Although dispersal distances depend on a number of factors, many weed species produce large numbers of seeds that are wind dispersed (Forman *et al*. 2003). For example, many of the species listed in the BC *Weed Control Regulation* belong to the sunflower family (*Asteraceae*), which is adapted for wind dispersal. Forman *et al*. (2003) found that the spread of non-native, invasive species could extend up to 1 km from the disturbed area.

Wildlife habitat resources are important vegetation-related components of ecosystems encountered by the Project. A 2 km wide Vegetation RSA corresponds with the Wildlife LSA for the Project, which will facilitate accurate mapping, modeling and assessment of wildlife habitat at a scale where it is most likely to be affected by Project construction and operations.

In addition, the physical footprint of the proposed construction right-of-way represents a non-trivial proportion of the land base within a 2 km wide Vegetation RSA buffer, allowing for meaningful assessment of potential effects to native vegetation species and communities within a greater ecological context.

Based on the above concepts, the Vegetation RSA generally consists of a 2 km wide band from the centre of the proposed pipeline corridor (*e.g.*, 1 km on both sides of the centre of the proposed pipeline corridor) was established to assess Project-related effects to vegetation resources. The spatial boundaries of the Vegetation RSA are shown on Figures 5.9-1 to 5.9-4.

7.2.9.3 Ecological Context

Different ecosystem classification systems are applied to portions of the proposed pipeline corridor within BC and Alberta. In BC, the Biogeoclimatic Ecosystem Classification (BEC) System identifies biogeoclimatic (BGC) zones and subzones. Alberta ecosystems are identified as Natural Regions and Subregions.

The proposed pipeline corridor encounters five Natural Subregions in Alberta: the Central Parkland; Dry Mixedwood; Central Mixedwood; Lower Foothills; and Montane Subregions (Natural Regions Committee 2006). The proposed pipeline corridor encounters 10 BGC zones in BC: the ICH Zone; the SBS Zone; the IDF Zone; the PP Zone; the BG Zone; the MS Zone; the CWH Zone; the ESSF; and the MH Zone. Further information regarding vegetation characteristics for the BGC Zone and Natural Subregions traversed by the proposed pipeline corridor are described in more detail in the Vegetation Technical Report of Volume 5C.

The pipeline corridor encounters a diversity of land uses including native vegetation (*e.g.,* treed, native prairie), agriculture (*e.g.,* cultivation, tame pasture, hay) and commercial/industrial development. The Edmonton to Hinton Segment traverses lands dominated by human impact (*i.e.*, cities, towns, agriculture, roads, pasture), with urban land use dominating in the east. Forested areas and other native land uses (*i.e.*, rivers, wetlands, regenerating burn areas) make up approximately 30% of this segment. The Hargreaves to Darfield Segment traverses a wide variety of terrain, including flat or gently undulating valley bottoms, hills, steep slopes and narrow valleys. Forested lands dominate this segment, with wetlands, streams and fens interspersed along the landscape, while urban land use and agriculture are encountered around the communities and towns along the corridor. The Black Pines to Hope Segment encounters a variety of land uses, including forested areas, grasslands, watercourses and wetlands. Human impacted land use in this segment includes agriculture and urban development around the communities, including the City of Kamloops. The Hope to Burnaby Segment is dominated by human land use, including agriculture and urban development primarily to the west in the Lower Mainland. To the east, native land uses include forested and riparian areas. The Burnaby to Westridge Segment is located within the Lower Mainland and is dominated by urban and industrial land use, with residual forest stands from RK 1.0 to RK 1.93 and RK 2.84 to RK 3.6. For more details on land use along the proposed pipeline corridor, see the Vegetation Technical Report of Volume 5C and the Environmental Alignment Sheets of Volume 6E.

Construction and operations of the proposed pipeline will create new forest clearing, increase the existing corridor width where existing linear disturbances are paralleled, remove potential site-specific vegetation communities, and require on-going clearing as part of vegetation management during operations. This will result in the long-term conversion of forest vegetation communities to earlier seral stages (forb and shrub stages) until the pipeline is abandoned and disturbed areas are reclaimed. Grassland/shrubland and wetland vegetation communities will be temporarily disturbed during construction but will be revegetated with native vegetation or allowed to revegetate naturally following pipeline construction.

Pipeline and operations activities have the potential to directly and indirectly affect vegetation resources through alteration of vegetation, terrain and drainage, causing changes in habitat availability and effectiveness. Direct effects on vegetation will occur during the construction phase of the Project, while the indirect effects on vegetation will occur post-construction and into the operations phase of the Project.

Construction of the proposed pipeline is expected to extend over approximately 2 years in total (including clearing and site preparation, construction and testing). An area over the centreline of the pipeline will be maintained with low vegetation over the life of the operating pipeline to meet regulatory and safety requirements, resulting in a long-term conversion of forested habitat to earlier seral stages along most of the pipeline length. Weed control and maintenance activities will be conducted throughout the operations of the Project.

The proposed Project parallels existing rights-of-way for approximately 89% of its length. Following construction, revegetation measures are planned to reclaim the lands affected by construction activities (see the Pipeline EPP of Volume 6B).

Native vegetation relates to other ecosystem components by providing: protection of gene pools for future use; protection of native plant and wildlife species and their habitats; protection of traditionally used plants and their habitats; preservation of climax ecosystems and native biodiversity; and conservation of representative samples of different habitat characteristics of the regions in which the proposed pipeline corridor is located.

Aboriginal people have used vegetation resources for a wide variety of cultural, social and economic uses: for consumption; to produce trade items; and for commercial sale to traders and non-indigenous people in contemporary and historical times (Lifeways of Canada Ltd 2012, Northern Gateway Pipelines Limited Partnership [NGPLP] 2010, Tomkins 2008). Today, Aboriginal communities continue to harvest medicinal and food plants on Crown land within their traditional territories (MacPherson Leslie & Tyerman LLP 2011, NGPLP 2010). During field surveys, it was reported by TEK participants that the plants of traditional economic value for food and cultural well-being include a variety of medicinal and berry species, as well as roots and bark of specific trees observed along the proposed pipeline corridor (see the Vegetation Technical Report of Volume 5C for more details of vegetation-related TEK).

Resilience is the capacity of a system to absorb disturbance, undergo change and still retain essentially the same function, structure, identity and feedbacks. It is generally understood that the resilience of some communities is greater than others (*e.g.,* lower elevation valley bottom communities are more resilient than higher elevation subalpine or alpine vegetation communities). Additionally, it is generally thought that upland mixedwood and moist coniferous forests are more resilient than wetland and drainage vegetation communities due to these communities' dependence upon the current hydrology.

The sensitivity of vegetation community types is complex and may vary depending on the age of the community, as well as local ecological components including species composition, topography, soil texture and hydrology. Disturbance to ecological components may influence the ability for a community to reclaim to pre-construction conditions. Selection of effective construction techniques and development of site-specific mitigation measures aim to reduce the magnitude of disturbance to these ecological conditions and effects in the affected vegetation community. Efforts will be made to successfully reclaim the areas traversed by the proposed pipeline corridor to an equivalent land use based on pre-construction conditions.

Vegetation species at risk include vascular and nonvascular (moss and liverwort) plant species and lichen species that are listed on Schedule 1 of the federal *Species at Risk Act* (Environment Canada 2013c). Plant species at risk that could occur in the study area were identified by referring to the list of COSEWIC and/or *Species at Risk Act*-designated plants (Environment Canada 2013c), using draft critical habitat maps (Environment Canada 2013d) and reviewing habitat/substrate preferences of species at risk and reviewing imagery using data from ACIMS (ACIMS 2012) and the BC CDC Species and Ecosystems Explorer tool (BC CDC 2013). Vegetation surveys were conducted for the Project in 2013.

Mapping of draft proposed critical habitat for whitebark pine and toothcup meadow-foam was provided by Environment Canada (Environment Canada 2013d). Environment Canada provided Project-specific hard-copy maps of critical habitat for species at risk in BC (Environment Canada 2013d). The information on critical habitat is provided in this report with permission from Environment Canada and this information is subject to change since critical habitat mapping is not final until posted in a final recovery strategy on the Species at Risk Public Registry. Environment Canada makes no representation and gives no warranty of any kind with respect to the accuracy, usefulness, novelty, validity, scope, completeness or currency of the Canada Digital Data and expressly disclaims any implied warranty of merchantability or fitness for a particular purpose of the Canada Digital Data.

Candidate Critical Habitat for Species at Risk have been developed by Environment Canada, though recovery strategies for toothcup meadow-foam and whitebark pine are not final (Environment Canada 2013c). The critical habitat for whitebark pine is in the "early candidate (pre-review)" stage, meaning that the Recovery Strategy has not yet completed an internal review. The toothcup meadow-foam critical habitat is in the "candidate (jurisdictional review)" stage, meaning that the Recovery Strategy has completed an internal review and has been partially vetted by the Government of BC and (if relevant) other *Species at Risk Act* participating agencies (*e.g.,* Fisheries and Oceans Canada or Parks Canada).

There are eight COSEWIC and/or *Species at Risk Act*-listed plant and lichen species that have the potential to occur within the Vegetation RSA and these are listed in Table 7.2.9-2.

TABLE 7.2.9-2

FEDERAL PLANT AND LICHEN SPECIES OF CONCERN WITH HISTORICAL OCCURRENCES RECORDED WITHIN THE VEGETATION REGIONAL STUDY AREA

Federal						
COSEWIC Designation[1]	*Species at Risk Act* Designation[2]	Common Name	Scientific Name	Type	Segment	Notes
Endangered	Endangered	silver hair moss	*Fabronia pusilla*	moss	Hope to Burnaby	In Canada, silver hair moss has only been found at two sites in BC: near Lower Arrow Lake in the Kootenay Valley and on the west end of Sumas Mountain east of Abbotsford. Silver hair moss grows on semi-exposed rock or the surface of tree bark (COSEWIC 2002b, 2012a). A previously recorded occurrence of silver hair moss was recorded approximately 1 km from the proposed pipeline corridor.
Endangered	Endangered	tall bugbane	*Actaea elata*	vascular plant	Hope to Burnaby	In Canada, there are seven extant populations of tall bugbane, as well as one historic and two unverified populations, all found sporadically in the Chilliwack River valley west of the Coast-Cascade Mountain range in BC (Penny and Douglas 2001). It grows in shady, moist, mixed, mature western redcedar, hemlock and Douglas-fir forest, but also in predominately deciduous stands. Previously recorded occurrences of tall bugbane range from approximately 1 km to 11 km from the proposed pipeline corridor and correspond to the locations in the Chilliwack River valley from Bridal Veil Provincial Park, BC to just west of Cultus Lake, BC.
Endangered	Endangered	toothcup meadow-foam	*Rotala ramosior*	vascular plant	Black Pines to Hope	In BC, toothcup meadow-foam is found along Kamloops Lake and Osoyoos Lake (COSEWIC 2012b). Previously recorded occurrences of toothcup meadow-foam range from less than 1 km to 4 km from the proposed corridor, corresponding to the Kamloops location. Candidate critical habitat for toothcup meadow-foam overlaps with the proposed corridor (Environment Canada 2013d).
Endangered	Endangered	whitebark pine	*Pinus albicaulis*	vascular plant	Hargreaves to Darfield Black Pines to Hope	In Canada, whitebark pine extends from the Canada-US border to about 200 km north of Fort Saint James in the Coast Mountains and to about 150 km north of Jasper in the Rocky Mountains (COSEWIC 2010a). It occurs typically in high elevation, upper subalpine habitats ranging from timberline down to closed subalpine forest. Previously recorded occurrences of whitebark pine range from approximately 5 km to greater than 100 km from the proposed corridor with the closest occurrences north of Valemount, BC and the other occurrences in Manning Provincial Park, BC. Early candidate critical habitat for whitebark pine occurs within 1 km of the proposed corridor in two locations (Environment Canada 2013d).
Threatened	Threatened	Haller's apple moss	*Bartramia halleriana*	moss	Hargreaves to Darfield	The Canadian range of Haller's apple moss includes western Jasper National Park, Alberta and adjacent BC along the Rocky Mountain trench. A total of 15 extant populations are known. The species is a habitat specialist, restricted to non-calcareous cliffs or talus in low elevation forests with high humidity and it has low dispersal ability (COSEWIC 2011a). Previously recorded occurrences of Haller's apple moss range from less than 1 km to 70 km from the proposed pipeline corridor with the closest occurrence at Avola, BC.
Threatened	Threatened	Mexican mosquito fern	*Azolla mexicana*	vascular plant	Hargreaves to Darfield	In Canada, Mexican mosquito fern is restricted to BC. The eight extant populations occur in three areas of south central BC: the Little Fort/North Thompson River area; the Shuswap Lake area; and Vernon (COSEWIC 2008). It is a shade-tolerant species found along the shores or in primarily still-waters of lakes, ponds, streams and other wetlands as well as in ditches. Previously recorded occurrences of Mexican mosquito fern range from approximately 100 m to 94 km from the proposed pipeline corridor, with the closest occurrence at Little Fort.

TABLE 7.2.9-2 Cont'd

Federal						
COSEWIC Designation[1]	*Species at Risk Act* Designation[2]	Common Name	Scientific Name	Type	Segment	Notes
Special Concern	Special Concern	Vancouver Island beggarticks	*Bidens amplissima*	vascular plant	Hope to Burnaby	In Canada, Vancouver Island beggarticks has been found in the Lower Fraser Valley (from east of Abbotsford to Richmond, BC) and on southern Vancouver Island, with one additional record on the mainland coast of BC just north of Vancouver Island (COSEWIC 2012c). It is a wetland species generally limited to habitat around ponds, lakes and stream margins where water levels fluctuate. Vancouver Island beggarticks show a distinct preference for silty alluvial soils. The species may also occur in tidal zones where it is inundated twice a day, and dries out between tides. Previously recorded occurrences of Vancouver Island beggarticks range from less than 1 km to greater than 100 km from the proposed corridor.
Special Concern	--	peacock vinyl lichen	*Leptogium polycarpum*	lichen	Hope to Burnaby	In Canada, peacock vinyl lichen is restricted to coastal BC. Populations have been found on southern Vancouver Island, mainland inlets and the main valleys of the Coast Range (COSEWIC 2011b). Previously recorded occurrences of peacock vinyl lichen range from less than 100 m to over 100 km from the proposed pipeline corridor with the closest occurrences near Bridal Falls and Hope.

Notes:

1. Committee on the Status of Endangered Wildlife in Canada (COSEWIC 2013). Species listed as Extirpated or Not at Risk were generally not included in the table without other noteworthy factors being present.

   Endangered: a species facing imminent extirpation or extinction.

   Threatened: a species likely to become Endangered if limiting factors are not reversed.

   Special Concern: a species that is particularly sensitive to human activities or natural events, but is not an Endangered or Threatened species.

2. *Species at Risk Act* (*SARA*). The *Act* establishes Schedule 1 as the list of species to be protected on all federal lands in Canada.

   Endangered: a species that is facing imminent extirpation or extinction.

   Threatened: a species that is likely to become an Endangered species if nothing is done to reverse the factors leading to its extirpation or extinction.

   Special Concern: a species that may become a Threatened or an Endangered species due to a combination of biological characteristics and identified threats.

7.2.9.4 Potential Effects and Mitigation Measures

Effects Considerations

Old growth forests are considered a vegetation community of concern. While old growth forests are not specifically listed by ACIMS or the BC CDC as specific rare ecological communities, they are identified in the regional management plans and environmental management plans of a number of regions and municipalities along the proposed pipeline corridor (Wildwood County, Yellowhead County, Chilliwack and Robson Valley). They were also mentioned during ESA Workshops and Community Workshops (*i.e.,* Burnaby and Clearwater) as a concern for stakeholders.

In general, definitions of old growth forest within the available research literature focus on the presence of structural characteristics such as large old living trees, large standing dead trees or snags (dead trees broken off at the top), complex canopy structure and coarse woody material (*i.e.*, logs) in both the terrestrial and aquatic environment (Franklin and Spies 1991, Geowest 1996, as reviewed in Braumandl and Holt 2000, Hilbert and Wiensczyk 2007). Old growth forests are widely recognized as being biologically diverse ecosystems (Franklin and Spies 1991). Structural characteristics result in microclimatic conditions utilized by specialized organisms (*e.g.,* lichens, amphibians) (Bunnell *et al.* 1999, Spies 1998) and provide habitat for fish, wildlife and plants (Bunnell *et al.* 1999, Geowest 1996, Spies 1998). The microhabitats available in old growth forests are high potential habitats for rare plant and lichen species, so old growth forest is discussed as it relates to habitat for rare plants/lichens and rare ecological communities in this assessment.

Approximately 33% of the total wildlife species found in BC occur in old growth forests (Bunnell *et al.* 1999). Obligate cavity nesters such as the pileated woodpecker are particularly abundant in old growth forest because of habitat preferences for large dead trees or snags (Bunnell *et al.* 1999, Franklin and Spies 1991). Old growth forests also constitute prime ungulate winter range because of high understory foliage availability, abundant litterfall (including lichens) and reduced snow depth due to canopy cover (Bunnell *et al.* 1999). Several species, including woodland caribou, are closely associated with old growth forests (Bunnell *et al.* 1999, Franklin and Spies 1991). For these reasons, and because the wildlife study areas consider larger areas than vegetation, old growth forest is also discussed in Section 7.2.10 Wildlife and Wildlife Habitat.

Old growth forests are also captured under the subsections discussing timber and Old Growth Management Areas (OGMAs) in the human occupancy and resource use sections (Sections 5.4 and 7.2.4) in Volume 5B. Late successional large trees are an important timber and forestry resource, and so are further discussed in the Managed Forest Areas and Forest Health Technical Report of Volume 5D.

Old growth forest also has spiritual and cultural value for many Aboriginal communities. Aboriginal communities along the Edmonton to Hinton, Black Pine to Hope and Hope to Burnaby segments raised concerns regarding clearing of old growth forest and mature tree stands. TEK will be discussed throughout this assessment and in more depth in the Vegetation Technical Report of Volume 5C and the Traditional Land and Resource Use Technical Report of Volume 5D.

Forest pests can pose a serious threat to mature coniferous forests. Management Strategies are provided by ASRD for mountain pine beetle and spruce budworm; however, only measures related to the management of mountain pine beetle pertain to activities associated with pipeline construction (*i.e.*, clearing, timber harvest and slash disposal). Bark beetles such as mountain pine beetle, Douglas-fir beetle and spruce beetle pose a serious threat to mature coniferous forests in BC. Emergency Bark Beetle Management Areas enable aggressive action in areas of bark beetle outbreak by way of designated emergency harvest strategies (BC Ministry of Forests and Range 2010). Although there are best practices which aim to prevent the introduction and spread of forest pests, many of the potential effects and mitigation is related to forestry practices and economic outcomes for forestry resources. Therefore, forest health was determined to be best discussed in the Managed Forest Areas and Forest Health Technical Report of Volume 5D, and an assessment of forest health is provided under the land and resource use indicator in Section 7.2.4 of Volume 5B. Therefore, forest pests are not further discussed in the vegetation assessment.

Vegetation communities of limited distribution are occasionally used to describe vegetation communities of concern. Communities of limited distribution are native ecosite or variant classes that cover less than 1% of the total Vegetation LSA or RSA. These communities contribute to landscape level diversity and have the potential to support plant species that do not occur elsewhere within the Vegetation LSA and RSA. This description is typically used for projects where the footprint is a facility or site in one particular region. This Project covers diverse landscapes and traverses a large number of Natural Subregions and BGCs. It was determined that interpreting the vegetation communities of concern indicator as communities of limited distribution would lose its meaning on a project of this scale where there are numerous areas of distinct and unique habitat. Instead, vegetation communities of limited distribution is represented by vegetation communities most affected, that investigates which communities (identified as variants in BC and ecosites in Alberta) in the Vegetation RSA occur along the Project Footprint more frequently than other vegetation communities in the RSA. These vegetation communities will be disproportionally affected by construction and maintenance activities and provide a focused discussion of effects to particular native vegetation communities.

Identified Potential Effects

Potential effects associated with the construction and operations of the proposed pipeline on vegetation indicators are listed in Table 7.2.9-3. These interactions are based on the results of the literature review, desktop analysis, field work, mapping, TEK, engagement with Aboriginal communities, landowners, regulatory authorities and other stakeholders (Section 3.0) and the professional experience of the assessment team.

The mitigation measures provided in Table 7.2.9-3 provide a summary of key mitigation measures selected to reduce effects to vegetation resources. These measures were principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines including, however, are not limited to, the following:

- Environmental Handbook for Pipeline Construction (AENV 1988);
- Guide for Pipelines Pursuant to the *Environmental Protection and Enhancement Act* and Regulations (AENV 1994a);
- Environmental Protection Guidelines for Pipelines: Conservation and Reclamation Information Letter, C&R/IL/94-5 (AENV 1994b);
- Best Management Practices for Pipeline Construction in Native Prairie Environments (AENV 2003b);
- Weeds on Industrial Development Sites: Regulations and Guidelines, R&R/03-4 (AENV 2003c);
- Recommended Land Use Guidelines for Protection of Selected Wildlife Species and Habitat within Grassland and Parkland Natural Regions of Alberta (ASRD 2011);
- Information Bulletin 2010-17 Preventing Spread of Invasive Plants and Noxious Weeds (BC OGC 2010b);
- Environmental Protection and Management Guidelines (BC OGC 2013);
- *Oil and Gas Activities Act* Environmental Protection and Management Regulation (BC Reg. 200/2010);
- Environmental Assessment Best Practice Guide for Wildlife at Risk in Canada (CWS 2004);
- Best Management Guidelines for the Enhanced Approval Process (Government of Alberta 2011);
- Integrated Standards and Guidelines: Enhanced Approval Process (Government of Alberta 2013a); and
- Guidelines for Translocation of Plant Species at Risk in British Columbia (Maslovat 2009).

Any quantitative assessment of potential effects is based generally on the centre of the proposed pipeline corridor.

TABLE 7.2.9-3

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON VEGETATION

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Vegetation Indicator – Vegetation Communities of Concern				
1.1 Loss or alteration of native vegetation	All	Footprint	• Confine all pre-clearing/mowing and general clearing activities within the staked/flagged construction right-of-way boundaries. Adhere to clearing/mowing restrictions associated with watercourses, wetlands, sensitive environmental features and buffer areas (at watercourse and wetland crossings) in addition to those areas outlined in the resource-specific mitigation tables [Appendices E through Q]. • Maintain low vegetation or vegetated ground mat within the riparian buffer zone of watercourses and the vegetated buffer zone of wetlands, to the extent practical, by clearing only trees, walking-down low vegetation so low-lying vegetation remains intact. Limit grubbing of cleared/mowed trees/shrubs only to the trench line and work side area needed for the vehicle crossing to protect riparian areas [Section 8.1]. • Use hand clearing methods where directed by Trans Mountain's Lead Environmental Inspector and Inspector(s) to avoid or reduce disturbance to the ground surface on sensitive terrain [Section 8.1]. • Restrict root grubbing to the trench line, if feasible, and restrict root grubbing in wet areas, where practical, to avoid creation of bog holes, minimize surface disturbance and encourage re-sprouting/natural regeneration of deciduous trees and shrubs. See additional clearing and grubbing measures in Section 8.1. • Determine the extent of disturbance to native grasslands (*e.g.*, compaction, rutting) and prepare the surface prior to seeding as per discussions with Trans Mountain's Lead Environmental Inspector and Inspector(s) [Section 8.6]. • Use natural recovery as the preferred method of reclamation on wetlands [Section 8.6]. • Place erosion control blankets or coir matting [Erosion Control Matting Drawing in Appendix R], woody slash or log diversions [Rollback Drawing in Appendix R] along the right-of-way on erodible soils or wind exposed sites to provide micro-habitat and support plant establishment [Brush Wind Barrier Drawing and Staked Logs for Erosion Control Drawing in Appendix R] [Section 7.0 of Appendix C]. • Within the vicinity of the construction right-of-way, collect dormant woody plant material (deciduous stakes/brush) and select suitably sized transplants (small conifer/deciduous trees/shrubs) from a suitable donor site following approval from the applicable land manager [Section 7.0 of Appendix C]. • Use a grass cover crop and/or native grass seed mix that has been developed for use at riparian areas to support the establishment of installed and naturally regenerating native woody plant material and plants and to provide erosion protection in the short-term [Section 7.0 of Appendix C].	• Alteration of the composition of approximately 2,058 ha of native vegetation.

TABLE 7.2.9-3 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Loss or alteration of native vegetation (cont'd)	All	Footprint	• Implement plant protection measures (*e.g.,* soil mounds and berms, wind fencing and rollback) that work to minimize environmental stresses (*i.e.*, wind exposure, low soil moisture stress [desiccation]), to the extent feasible [Section 7.0 of Appendix C]. • Seed disturbed lands with land uses that support native and non-native plant communities with native and non-native grass mixtures and rates, respectively, as identified in the Reclamation Management Plan as per results of the vegetation field surveys [Appendix C] [Section 8.6]. • For native seed, the highest seed grade available will be obtained. Do not accept seed lots that contain any Prohibited Noxious or Noxious weeds as identified in the Certificate of Analysis. Retain the Certificates of Analysis obtained for both agronomic and native seed for future documentation. The Certificates of Analysis will be presented to the landowner/Crown land authority upon request [Section 8.6]. • Minimize foot traffic on newly seeded areas until grass establishment has taken place. Vehicle traffic will be avoided on seeded areas until the sod is re-established [Section 8.6] [Section 10.0 of Appendix C]. • Plant native shrub/tree species, where warranted, depending on the site-specific objectives [Section 14.0 of Appendix C]. • Remove problem vegetation (*i.e.*, weeds or invasive species) when adjacent to or crossing a wetland or watercourse and replace it with compatible, low-growing plant species that will out-compete problem vegetation [Section 14.0 of Appendix C]. • Refer to the Problem Vegetation Management Plan [Sections 14 of Appendix C] for management of non-native or invasive species. • See potential effect 3.1 of this table for mitigation regarding non-native or invasive species during construction and operations. • Monitor the effectiveness of revegetation efforts during the PCEM of the construction rights-of-way. Conduct additional remedial work, where warranted.	• See above.
1.2 Loss or alteration of the most affected vegetation communities	Edmonton to Hinton[3] RK 0.5 to RK 2 RK 59 to RK 66 RK 80 to RK 83 RK 118.5 to RK 133.5 RK 126 to RK 127 RK 133 to RK 134 RK 152 to RK 165 RK 175 to RK 176.5 RK 207 to RK 207.5 Hargreaves to Darfield[3] RK 491 to RK 554 Black Pines to Hope[3] RK 981 to RK 1000	Footprint	• See potential effect 1.1 of this table for mitigation regarding alteration of native vegetation. • Conduct a pre-construction weed survey and record problem vegetation (designated weeds) infestations on and immediately adjacent to the construction right-of-way [Section 6.0] [Section 14.0 of Appendix C]. • Reduce grubbing of roots in shrubby communities within TWS areas, where feasible [Section 6.0 of Appendix C]. • Minimize grubbing of plant roots and stumps at non-graded areas, to the extent feasible, to promote re-sprouting of cleared/brushed deciduous vegetation and germination of the undisturbed soil seed bank to optimize the potential for the natural regeneration of vegetation and reduce the potential for terrain instability or soil erosion by wind or water at these sites [Section 7.0 of Appendix C]. • Mow or walk down rather than wholly remove shrubs, where feasible [Section 6.0 of Appendix C]. • Clear woody vegetation only to the extent warranted to reduce the loss of forest values and minimize the potential for terrain instability and erosion [Section 7.0 of Appendix C].	• Alteration of up to approximately 6.4% of a variant or ecosite.

TABLE 7.2.9-3 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.2 Loss or alteration of the most affected vegetation communities (cont'd)	See above	Footprint	• Use protective matting and/or snow during the winter to mat over the vegetation community where it occurs and other areas where surface disturbance is not required, to protect communities from scraping and compacting [Section 6.0 of Appendix C]. • Monitor the amount of mulch (wood chips) produced during mulching of un-grubbed tree stumps where minimum disturbance construction techniques are used on the construction right-of-way (grubbing and topsoil salvage over the trench only) so as to maintain soil nutrients at levels (*i.e.*, maintain a suitable Carbon:Nitrogen ratio) that can support vegetation re-establishment following construction activities [Section 7.0 of Appendix C]. • Consider employing appropriate salvage, propagation and transplant techniques for component species [Section 6.0 of Appendix C]. • Manage all problem vegetation along the construction right-of-way during all pipeline construction phases (*i.e.*, pre-construction, construction, PCEM) and the operational phase [Section 14.0 of Appendix C]. • Monitor the effectiveness of revegetation efforts during the post-construction environmental monitoring of the construction rights-of-way. Conduct additional remedial work, where warranted.	• See above.
1.3 Loss or alteration of grasslands in the BG BGC Zone	Black Pines to Hope RK 829.4 to RK 848.8 RK 849.7 to RK 850.8 RK 896.8 to RK 897.0 RK 897.5 to RK 898.5 RK 899.0 to RK 899.1 RK 918.5 to RK 921.4 RK 922.7 to RK 933.0	LSA	• See potential effect 1.1 of this table for mitigation regarding alteration of native vegetation. • Supplemental vegetation and rare plant surveys will be conducted prior to construction. See Section 9.0 for details. • Conduct a pre-construction weed survey and record problem vegetation (designated weeds) infestations on and immediately adjacent to the construction right-of-way [Section 6.0] [Section 14.0 of Appendix C]. • Avoid environmentally sensitive areas, such as areas likely to have rare ecological communities. Where avoidance is impractical, develop site-specific mitigation measures in accordance with the Rare Ecological Community and Rare Plant Population Management Plan [Section 6.0 of Appendix C]. • Avoid creating new disturbances and use of treed areas or native grasslands when selecting ancillary sites, to the extent feasible [Section 12.0]. • Consider employing appropriate salvage, propagation and transplant techniques for component species [Section 6.0 of Appendix C]. • Retain sod and the vegetation mat on all lands if a competent sod layer exists. In these areas, grade only where safety considerations dictate in order to reduce disturbance to sod and the vegetation mat. Grading of well-sodded lands will not be permitted on level terrain [Section 8.2]. • Minimize trench width on native grasslands during trenching, to the extent feasible, in order to limit spoil storage requirements and sod disturbance [Section 8.3]. • Reduce the topsoil/root zone material salvage width at localized sensitive areas as shown on the Environmental Alignment Sheets or as directed by the Lead Environmental Inspector and Inspector(s) [Section 8.2].	• Some disturbance or alteration of grassland communities in the BG BGC Zone.

TABLE 7.2.9-3 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.3 Loss or alteration of grasslands in the BG BGC Zone (cont'd)	See above	LSA	• Salvage a blade width of topsoil/root zone material centered over the trench at locations indicated on the Environmental Alignment Sheets. Disc well-sodded lands prior to topsoil/root zone material salvage in order to facilitate topsoil salvage operations [Section 8.2]. • Backfill the trench as soon as practical [Section 8.4]. • Conduct straw crimping on disturbed agricultural or native grassland soils where wind erosion may be problematic. Prior to spreading and crimping of straw, confirm that approval from the landowner or appropriate regulatory authority is in place, where warranted. Straw used will be obtained from: the landowner where the straw will be spread; a Certified seed grower; or fields or bales that have been inspected to be free of weeds [Section 8.6]. • Employ a subsoiler plow (*e.g.,* Paratiller) along segments of the construction right-of-way adjacent to the ditchline where topsoil salvage did not occur and subsoil compaction is severe. Do not use a subsoiler plow on native grasslands [Section 8.6]. • Avoid scalping of the vegetation mat/sod layer during topsoil/root zone material replacement on cleared/ungrubbed riparian vegetation, native grasslands, hay and tame pasture. Use specialized equipment (*e.g.,* clean-up bucket) that limits the risk of scalping during the final pass of topsoil/root zone material replacement and is approved by Trans Mountain's Inspector(s) [Section 8.6]. • Determine the extent of disturbance to native grasslands (*e.g.,* compaction, rutting) and prepare the surface prior to seeding as per discussions with Trans Mountain's Lead Environmental Inspector and Inspector(s) [Section 8.6]. • Manage all problem vegetation along the construction right-of-way during all pipeline construction phases (*i.e.*, pre-construction, construction, post-construction environmental monitoring) and the operational phase [Section 14.0 of Appendix C]. • Limit vehicle travel through problem vegetation infested areas [Section 14.0 of Appendix C]. • Refer to potential effect 3.1 of this table for mitigation regarding non-native or invasive species and herbicide use during construction and operations. • Monitor the effectiveness of revegetation efforts during the post-construction environmental monitoring of the construction rights-of-way. Conduct additional remedial work, where warranted.	• See above.
1.4 Loss or alteration of rare ecological communities	Edmonton to Hinton beaked sedge marsh (S2) RK 257.07 beaked willow/red-osier dogwood (S3?) RK 100.92 to RK 100.98 white birch/stiff club-moss woodland (S2?) RK 141.61 to RK 141.65 RK 141.79 to RK 141.82 RK 141.87 to RK 141.92 Hargreaves to Darfield common cattail marsh (S3, Blue)	LSA	• See potential effect 1.1 of this table for mitigation regarding alteration of native vegetation. • See recommended mitigation measures for wetland ecological communities of concern outlined in Table 7.2.8-2 Wetland Loss or Alteration. • Supplemental vegetation and rare plant surveys will be conducted prior to construction. See Section 9.0 for details. • Avoid environmentally sensitive areas, such as areas likely to have rare plant species or rare ecological communities. Where avoidance is impractical, implement site-specific mitigation measures in accordance with the Rare Ecological Community and Rare Plant Population Management Plan [Section 6.0 of Appendix C].	• Some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site.

TABLE 7.2.9-3 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.4 Loss or alteration of rare ecological communities (cont'd)	RK 728.75 to RK 728.77 lodgepole pine/velvet-leaved blueberry/clad lichens (S2S3, Blue) RK 509.4 RK 509.8 to RK 509.85 RK 510.49 to RK 510.59 RK 523.36 to RK 523.53 RK 534.83 to RK 535.14 RK 546.68 to RK 546.86 western redcedar - paper birch/oak fern (S2S3, Blue) RK 749.71 to RK 749.81 Black Pines to Hope amabilis fir - western redcedar/devil's club (S3, Blue) RK 1007.91 RK 1013.19 big sagebrush/bluebunch wheatgrass (S2, Red) RK 927.29 to RK 927.54 hybrid spruce species - Douglas-fir/subalpine fir (unique community) RK 978.12 narrow-leaf willow shrubland (S2, Red) RK 847.11 to RK 847.17 RK 847.26 to RK 847.27 Hope to Burnaby black cottonwood –red alder/salmonberry (S3, Blue) RK 1142.54 to RK 1142.76 RK 1145.62 to RK 1145.64 common cattail marsh (S3, Blue) RK 1116.58 to RK 1116.61 western redcedar – Sitka spruce/skunk cabbage (S3?, Blue) RK 1142.9 to RK 1143.03	LSA	• Conduct native seed collection for use in revegetation efforts at the site [Section 6.0 of Appendix C]. • Consider employing appropriate salvage, propagation and transplant techniques for component species [Section 6.0 of Appendix C]. • If previously unidentified occurrences of vegetation communities of concern are found during supplemental rare plant surveys, mitigation will be determined using the Rare Ecological Community and Rare Plant Population Management Plan [Section 6.0 of Appendix C]. • Site-specific mitigation will include avoidance, narrowing the construction right-of-way, fencing or protecting [Section 6.0 of Appendix C, Appendix J]. • Flag or fence-off resource-specific environmental features (*e.g.,* rare plant species, rare ecological communities) prior to commencing construction in the vicinity of the resource site. See additional mitigation in Section 6.0 of the Pipeline EPP. • Implement the resource-specific mitigation measures associated with vascular and non-vascular plant species of concern as well as rare and unique plant communities on or adjacent to the staked construction boundaries as outlined in the environmental resource-specific mitigation tables for rare plant/rare ecological communities provided in Appendix J and as shown in the Environmental Alignment Sheets [Section 6.0]. • Suspend activity if previously unidentified rare ecological communities are found on or adjacent to the construction right-of-way. Implement the Rare Ecological Communities or Rare Plant or Species Discovery Contingency Plan [Section 7.0 of Appendix B]. • Fence off the area where the rare plant community is traversed [Narrow Down Fencing Drawing in Appendix R] [Section 6.0 of Appendix C]. • Water down construction sites and access roads, when warranted, to reduce or avoid the potential for dust emissions. Increase the frequency of watering roads and sites during periods of high risk (*e.g.,* high winds). Implement additional dust abatement measures (*e.g.,* covering topsoil windrows, installing sediment fences, applying a tackifier) will be implemented, when warranted, during clearing and construction activities. See additional measures to control dust in Section 8.2 of the Pipeline EPP. • Place erosion control blankets or coir matting [Erosion Control Matting Drawing in Appendix R], woody slash or log diversions [Rollback Drawing in Appendix R] along the right-of-way on erodible soils or wind exposed sites to provide micro-habitat and support plant establishment [Brush Wind Barrier Drawing and Staked Logs for Erosion Control Drawing in Appendix R] [Section 7.0 of Appendix C]. • Conduct straw crimping on disturbed agricultural or native grassland soils where wind erosion may be problematic [Section 8.6]. • Seed disturbed erodible soils on non-cultivated land with a mixture of approved agronomic or native seed and cover crop seed such as fall rye if seeding in late summer or annual oats if seeding in the winter, spring or early summer [Section 8.6].	• If rare ecological communities are located adjacent to the construction right-of-way, they may be indirectly affected by changes in hydrology or light levels.

TABLE 7.2.9-3 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.4 Loss or alteration of rare ecological communities (cont'd)	See above	LSA	• Implement plant protection measures (*e.g.,* soil mounds and berms, wind fencing and rollback) that work to minimize environmental stresses (*i.e.*, wind exposure, low soil moisture stress [desiccation]), to the extent feasible [Section 7.0 of Appendix C]. • Recontour the landscape to pre-construction conditions [Section 7.0 of Appendix C]. • Restrict the application of herbicide within 30 m of known rare plant populations or rare ecological communities. Spot spraying, wicking, mowing or hand-picking are acceptable weed control measures in proximity to rare plants, rare lichens and vegetation communities of concern [Section 7.0]. • Monitor the effectiveness of revegetation efforts during the post-construction environmental monitoring of the construction rights-of-way. Conduct additional remedial work, where warranted.	• See above.
2. Vegetation Indicator – Plant and Lichen Species of Concern				
2.1 Loss or alteration of rare plant and/or lichen occurrences	All (See Table J-1 of Appendix J of the EPP of Volume 6B for detailed locations)	LSA	• Supplemental vegetation and rare plant surveys will be conducted prior to construction. See Section 9.0 for details. • See potential effect 1.4 of this table for mitigation applicable to the loss or alteration of rare ecological communities. • Flag or fence-off resource-specific environmental features (*e.g.,* rare plant species, rare ecological communities) prior to commencing construction in the vicinity of the resource site See additional measures in Section 6.0 of the Pipeline EPP. • Apply only water or non-toxic and non-persistent chemical products as approved to access roads for dust control at park locations or sensitive areas including agricultural crop production areas, especially berries [Section 9.0]. • Water down construction sites and access roads, when warranted, to reduce or avoid the potential for dust emissions. Increase the frequency of watering roads and sites during periods of high risk (*e.g.,* high winds). Implement additional dust abatement measures (*e.g.,* covering topsoil windrows, installing sediment fences, applying a tackifier) will be implemented, when warranted, during clearing and construction activities. See additional measures to control dust in Section 8.2 of the Pipeline EPP. • Recontour the landscape to pre-construction conditions [Section 7.0 of Appendix C]. • Monitor the effectiveness of revegetation efforts during the post-construction environmental monitoring of the construction rights-of-way. Conduct additional remedial work, where warranted.	• Some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • Some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare plant or lichen sub-populations are located adjacent to the construction right-of-way they may be affected by changes in dust, hydrology or light levels. • If vegetation species at risk sub-populations are located adjacent to the construction right-of-way they may be affected by changes in dust, hydrology or light levels.

TABLE 7.2.9-3 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern				
3.1 Weed introduction and spread	All	RSA	• Conduct a pre-construction weed survey and record problem vegetation (designated weeds) infestations on and immediately adjacent to the construction right-of-way [Section 6.0] [Section 14.0 of Appendix C]. • Implement weed management (*i.e.*, using proper application of chemical, mechanical or manual measures, or a combination of all) at locations identified within the pre-construction weed survey to a level that is consistent with weed management observed adjacent to the eventual construction right-of-way to reduce the potential for weed infestations following construction [Section 6.0]. Also refer to the Weed and Vegetation Management Plan [Section 14.0 of Appendix C]. • Ensure equipment arrives at all construction sites clean and free of soil or vegetative debris. Do not allow any equipment arriving in a dirty condition on site until it has been cleaned [Section 7.0]. • Power wash and misting stations will be established, where required, to clean equipment used during clearing and topsoil handling activities [Appendix F]. Basic shovel and sweep cleaning will be conducted on clearing and topsoil handling equipment before moving equipment off of cultivated fields. In addition, shovel and compressed air cleaning stations for topsoil handling equipment will be established at selected locations to prevent the spread of weeds [Appendix J] [Section 5.2]. • Restrict all vehicular traffic to the approved and staked construction right-of-way, workspace and access roads [Section 6.0]. • Monitor the topsoil and other soil piles for weed growth frequently during the growing season. Direct the contractor when warranted to take proactive measures to control weed growth [Section 7.0]. • Consider placing mats (*i.e.*, construction mats or swamp mats) over infested areas to reduce construction equipment transporting weed or plant material. Where mats are used, ensure they are free of soil, vegetation and debris prior to removing from the site [Section 7.0]. • Consider salvaging topsoil from the full construction right-of-way during non-frozen conditions if localized weed infestations are encountered, as outlined in the Weed and Vegetation Management Plan [Section 7.0] [Section 14.0 of Appendix C]. • Clean equipment (*i.e.*, shovel and sweep, pressurized water or compressed air) involved in topsoil/root zone material handling at weed-infested sites prior to leaving the location unless full right-of-way topsoil/root zone material salvage has been conducted. Clean equipment involved in topsoil handling at weed-infested sites prior to leaving the location [Section 7.0]. • Conduct straw crimping on disturbed agricultural or native grassland soils where wind erosion may be problematic. Prior to spreading and crimping of straw, confirm that approval from the land owner or appropriate regulatory authority is in place, where warranted. Straw used will be obtained from: the landowner where the straw will be spread; a Certified seed grower; or fields or bales that have been inspected to be free of weeds [Section 8.6].	• Weed introduction and spread.

TABLE 7.2.9-3 Cont'd

Potential Effect	Pipeline Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.1 Weed introduction and spread (cont'd)	All	RSA	• Use only Certified Canada No. 1 or the best available agronomic seed. For native seed, the highest seed grade available will be obtained. Do not accept seed lots that contain any Prohibited Noxious or Noxious weeds as identified in the Certificate of Analysis. Retain the Certificates of Analysis obtained for both agronomic and native seed for future documentation. The Certificates of Analysis will be presented to the landowner/Crown land authority upon request [Section 8.6]. • Limit vehicle travel through problem vegetation infested areas [Section 14.0 of Appendix C]. • The Weed and Vegetation Management Plan consists of vegetation management measures to be implemented in the short-term, during the pre-construction, construction and PCEM phases of Project construction and the long-term, during the regular operations and maintenance phase of the Project. Vegetation management measures to be implemented during both short-term and long-term periods [Section 14.0 of Appendix C]. • The use of herbicides for problem vegetation management along the construction right-of-way during construction and operations within the province of Alberta will be conducted in accordance with the *Environmental Code of Practice for Pesticides* as part of the Alberta *Environmental Protection and Enhancement Act*, and in BC will be conducted in accordance with the *Integrated Pest Management Regulation* of BC as part of the BC *Integrated Pest Management Act* [Section 14.0 of Appendix C]. • Monitor the effectiveness of revegetation efforts during the post-construction environmental monitoring of the construction rights-of-way. Conduct additional remedial work, where warranted. • During regular maintenance and operations activities, incidental ground inspections for problem vegetation along the construction right-of-way may be conducted to determine the extent (percent cover, composition, distribution, location of infestations) of problem vegetation (*i.e.*, presence of mature brush and trees, and weeds). Areas of new infestations, recommended treatment sites and adjacent landowner concerns will also be identified and documented during monitoring. To assist monitoring efforts, the baseline data collected during the pre-construction weed survey and the results of the PCEM Program will assist in establishing thresholds and determining if objectives of the Weed and Vegetation Management Plan are being met [Section 14.0 of Appendix C].	• See above.

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).
3 All locations are approximations based on TEM.

7.2.9.5 Potential Residual Effects

The potential residual environmental effects on vegetation indicators associated with the construction and operations of the pipeline (Table 7.2.9-3) are:

- alteration of the composition of approximately 2,058 ha of native vegetation;
- alteration of up to approximately 6.4% of a variant or ecosite;

- some disturbance or alteration of grassland communities in the BG BGC Zone;
- some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare ecological communities are located adjacent to the construction right-of-way, they may be indirectly affected by changes in hydrology or light levels;
- some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site;
- some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare plant or lichen sub-populations are located adjacent to the construction right-of-way, they may be affected by changes in dust, hydrology or light levels;
- if vegetation species at risk sub-populations are located adjacent to the construction right-of-way they may be affected by changes in dust, hydrology or light levels; and
- weed introduction and spread.

7.2.9.6 Significance Evaluation of Potential Residual Effects

A quantitative analysis was undertaken to evaluate the significance of the potential residual environmental effects for the disturbance of native vegetation in the Footprint and the disturbance to vegetation communities of limited extent and grassland communities in the BG BGC Zone as these changes over the baseline data were quantifiable. However, for other potential effects where there are no standards, guidelines, objectives or other established and accepted ecological thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method is used. The qualitative method is based on available research literature, field experience and professional judgment and is considered to be the appropriate method for determining the significance of the anticipated residual environmental effects. Consequently, the qualitative assessment of vegetation is considered to be the most appropriate method with the evaluation of significance of the potential residual effects relying on the professional judgment of the assessment team.

Table 7.2.9-4 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the proposed pipeline on vegetation. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.2.9-4

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE CONSTRUCTION AND OPERATIONS ON VEGETATION

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Vegetation Indicator – Vegetation Communities of Concern									
1(a)	Alteration of the composition of approximately 2,219 ha of native vegetation.	Negative	Footprint	Short-term	Periodic	Medium to long-term	Low to medium	High	High	Not significant
1(b)	Alteration of up to approximately 6.4% of a variant or ecosite.	Negative	Footprint	Short-term	Periodic	Medium to long-term	Low	High	Moderate	Not significant
1(c)	Some disturbance or alteration of grassland communities in the BG BGC Zone.	Negative	LSA	Short-term	Periodic	Medium to long-term	Medium	High	Moderate	Not significant

TABLE 7.2.9-4 Cont'd

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
1(d)	Some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Periodic	Medium to long-term	Medium	High	High	Not significant
1(e)	If rare ecological communities are located adjacent to the construction right-of-way they may be indirectly affected by changes in hydrology or light levels.	Negative	LSA	Short-term	Periodic	Medium to long-term	Low	High	Moderate	Not significant
1(f)	Combined effects on the vegetation communities of concern indicator (1[a] to 1[e]).	Negative	LSA	Short-term	Periodic	Medium to long-term	Low to medium	High	Moderate	Not significant
2.	Vegetation Indicator – Plant and Lichen Species of Concern									
2(a)	Some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Periodic	Medium to long-term	Medium	High	High	Not significant
2(b)	Some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Periodic	Short to medium-term	Medium	High	High	Not significant
2(c)	If rare plant or lichen sub-populations are located adjacent to the construction right-of-way, they may be affected by changes in dust, hydrology or light levels.	Negative	LSA	Short-term	Periodic	Short to long-term	Low	High	High	Not significant

3.	Vegetation Indicator – Presence of infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern									
3(a)	Weed introduction and spread.	Negative	RSA	Short-term	Periodic	Short to medium-term	Low to medium	High	High	Not significant

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Vegetation Indicator – Alteration of Vegetation Communities of Concern

The following provides the evaluation of significance of potential residual effects on the vegetation communities of concern indicator.

Alteration of Native Vegetation

Although some previous clearing has occurred in the Vegetation RSA for the Project, most of the vegetation communities within the Vegetation RSA in BC remain intact. The Project parallels existing disturbance for 89% of its length. The east and west ends of the Project are areas with a high level of anthropogenic disturbance (*i.e.,* Edmonton and LMDA). The land use in the Vegetation RSA along the Edmonton to Hinton Segment is mostly anthropogenic (*e.g.,* cultivation, pasture, roads), with between 25-39% native vegetation. The amount of native vegetation in the Vegetation RSA in BC is much higher than Alberta, with between 63-76% native vegetation. There are agricultural areas around Kamloops, but the degree of anthropogenic disturbance in the Vegetation RSA is generally low along the BC segments of the Project.

The proposed pipeline corridor was routed along existing rights-of-way and other linear disturbance to the extent practical. Using a disturbance layer on GIS imagery to calculate undisturbed native vegetation, approximately 2,058 ha of native vegetation may be disturbed or altered on the Footprint during construction and operations of the proposed pipeline. The alteration of native vegetation is considered to have a negative impact balance.

Disturbed areas through native vegetation segments on generally level terrain will be allowed to naturally regenerate, and areas in parks and protected areas will be seeded with the appropriate native seed mix. Cover crops will be used for initial soil stabilization and weed control. Although areas disturbed during construction and periodic maintenance activities will revegetate with the appropriate native species, species composition in the disturbed Footprint will be altered. Clearing of the right-of-way and temporary workspace and the maintenance of the right-of-way will result in the perpetuation of early seral vegetation. The extent of altered vegetation communities will be limited by the implementation of mitigation measures outlined in Table 7.2.9-3 and in the Pipeline EPP (Volume 6B) and reclamation measures will speed the recovery.

Specific learnings from the TMX Anchor Loop Project PCM (TERA 2013a) relevant to the alteration of native vegetation include the following.

- Localized broadcast-seeding of native forb species resulted in limited establishment success.
- Timely salvage, storage and replacement of topsoil/root zone material allowed for the preservation of propagules (*e.g.*, seed, root pieces, spores) located in the surface soil to remain viable.
- Native sod salvage and replacement proved successful with no observed difference in sod and adjacent seeded sites after 5 years of monitoring.
- Where grubbing was avoided in riparian areas adjacent to crossings of streams and wetlands, native deciduous plants re-sprouted the spring after clearing and native plants established from seed located within the undisturbed surface soil.
- Willow staking was an effective means of re-vegetating the banks of watercourses when coordinated with construction clean-up and reclamation.
- Protection of installed woody plant species from ungulate browsing was achieved through the use of constructive panel fencing.
- The establishment success of installed woody plant species and naturally-regenerating native forb species was observed in riparian areas with limited grass establishment due to dry and/or low nutrient soils (*i.e.*, gravelly or with high woody debris content) or where a native riparian seed mix was not applied. To improve survival success of installed woody species and to encourage species diversity through the natural regeneration of native plants from the soil seed bank, seed riparian areas with a short-lived perennial native grass species to stabilize surface soils and reduce competition to installed and naturally-regenerating plants.

Alteration of native vegetation due to competition for light, soil nutrients and moisture may occur while the Footprint is revegetating. However, the establishment of early successional communities during reclamation and operations will resemble revegetation following natural disturbance since the species composition will favor early successional/colonial species, which are adapted for greater competition pressure for light, nutrients and moisture (excepting the competition resulting from weedy non-native species).

During construction, operations and reclamation of the Project, there will be a decrease in woody species richness and abundance due to site clearing within the Footprint, but due to edge effects there may be increases in woody species richness and abundance in areas adjacent to the Footprint. The extra temporary workspace will be allowed to revegetate after construction. Forb and graminoid species richness and abundance will increase over the operations phase of the Project as natural, low growing vegetation regenerates, but the Footprint will be maintained free of higher growing vegetation. During abandonment, the Footprint will be returned to an equivalent land capability compared to the pre-construction conditions.

TEK participants raised concerns about clearing of native vegetation along all segments of the pipeline. Along the Edmonton to Hinton Segment, participants described that forested land regulates climate and provides wildlife habitat and expressed concern over several forested areas, including stands of poplar, aspen, mature spruce and old growth forest (locations identified in Table 5.1.1-3 in the Vegetation Technical Report of Volume 5C). Participants along the Hargreaves to Darfield Segment expressed concern about the clearing of one tree stand (location identified in Table 5.1.2-3 in the Vegetation Technical Report of Volume 5C) and confirmed the importance of proper vegetation, tree and stump clearing to prevent resource waste. Participants along the Black Pines to Hope Segment expressed concern regarding loss of berry plants through clearing activities, namely huckleberries and soapberries, as well as concern about clearing of mature tree stands including Douglas-fir stands (locations identified in Table 5.1.3-3 in the Vegetation Technical Report of Volume 5C).

By preserving native vegetation using the mitigation highlighted in Table 7.2.9-3 and the Pipeline EPP of Volume 6B, the Project will achieve the objectives of the land use plans for the areas traversed by the proposed pipeline corridor. Objectives of the management plans include maintaining natural vegetation throughout the development process, preserving natural vegetation including trees in all undeveloped and riparian areas and discouraging further clearing or development in areas where native vegetation is important for soil conservation, water resources protection or wildlife habitat (City of Kamloops 2004, Strathcona County 2007, TNRD 2000, TNRD 2011b,c, Town of Edson 2006, Yellowhead County 2005, Yellowhead County 2006, Yellowhead County 2007). See Appendix 7.1 for more details of the land use plan objectives related to vegetation.

No locally or regionally adopted threshold or standard exists against which the incremental change in vegetation composition can be assessed. This residual effect is limited to the Footprint, reversible in the medium to long-term and of low to medium magnitude (Table 7.2.9-4, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – effects of pipeline construction and operations on the alteration of native vegetation is confined to the construction right-of-way.

- Duration: short-term – the events contributing to the alteration of native vegetation are clearing during construction of the pipeline or maintenance activities (*e.g.,* integrity digs, vegetation management), the latter of which are limited to any 1 year during the operations phase.

- Frequency: periodic – the events resulting alteration of native vegetation (*i.e.*, pipeline construction and maintenance activities) occur intermittently but repeatedly during the operations phase of the Project.

- Reversibility: medium to long-term – depending upon the associated land use and the growth time required for species in each affected area (*e.g.,* forb versus tree), changes to native vegetation community composition are considered reversible in the medium to long-term. The effects of the proposed pipeline on forb species (*e.g.,* grasses, bunchberry) is expected to be reversible in the medium-term, whereas the effects on tree species (*e.g.,* western redcedar, black spruce) are expected to be reversible in the long-term (more than 10 years) because the full right-of-way will be maintained free of higher growing vegetation until abandonment. Therefore, the overall alteration of the composition of vegetation along the Footprint will persist in the medium to long-term.

- Magnitude: low to medium – the proposed pipeline corridor is located adjacent to existing disturbances for 89% of the length and the construction of the pipeline will result in the clearing of approximately 2,058 ha of vegetation on the Footprint, which is considered to be within environmental standards given that best practices, objectives and provincial guidelines are being followed. Permanent loss of native vegetation is not anticipated to result from either the construction or operations of the proposed pipeline (low), however, returning the Footprint to an equivalent land capability during the abandonment phase could take years, as discussed under reversibility (medium). The indirect effects of Project construction and maintenance due to edge effects such as changes in light and moisture will be of low magnitude since they will not result in the loss of vegetation but only a localized change in vegetation community composition.

- Probability: high – the Footprint crosses native vegetation.
- Confidence: high – based on past pipeline projects and the professional experience of the assessment team.

Alteration of Up to 6.4% of a Variant or Ecosite

The proposed pipeline corridor was routed along existing rights-of-way and other linear disturbances to the extent practical. Certain vegetation communities, classified as variants and ecosites in BC and Alberta respectively, may be more affected than others due to the landscape and routing constraints. Vegetation communities located along the proposed pipeline corridor will have the potential to be altered such that their overall abundance may be reduced (although other native vegetation communities will be present).

Direct alteration of up to 6.4% of a variant or ecosite as a direct result of the Project has been quantitatively assessed within the Vegetation RSA using TEM.

Listed below in Table 7.2.9-5 are the ecosites whose total area (ha) on the Footprint, when compared to the ecosite total area (ha) in the Vegetation RSA, is more than 2.75% of the ecosite in the RSA.

Communities most affected were selected as those ecosites with more than 2.75% of the total ecosite located on the Footprint, based on the distribution of values between 0.5% and 6.4%. The total area of the ecosites listed in Table 7.2.9-5 within the Vegetation RSA may not be large; most of the ecosites (excluding the DMWk – rich fen) occupy less than 100 ha of the Vegetation RSA, while the Vegetation RSA occupies approximately 50,000 ha. However, these ecosites are disproportionately located along the Footprint (more than 2.75% of their total area within the Vegetation RSA is located along the Footprint), meaning that these ecosites will be more affected by the Project than other ecosites within the Vegetation RSA.

The most affected communities in Alberta are ecosites that are low lying to upland that occur on level to depressional areas (Beckingham and Archibald 1996, Beckingham *et al.* 1996). The ecosites vary from nutrient poor to medium with acidic soil conditions, dominated by lodgepole pine, black spruce, common Labrador tea, bog cranberry and common blueberry (Labrador tea-mesic), to alkaline nutrient rich fens characterized by tamarack, dwarf birch or willow and sedges (Beckingham and Archibald 1996). The ecosite most affected by the Project (6.4%) is a marsh ecosite found along shorelines of water bodies and riparian zones. This ecosite is thought of as successionally stable with changes in plant community composition being determined largely by disturbance regime (Beckingham *et al.* 1996).

TABLE 7.2.9-5

NATIVE VEGETATION COMMUNITIES MOST AFFECTED BY THE PROJECT IN ALBERTA[1]

Natural Subregion	Ecosite[2]	Area of Ecosite within Project Footprint (ha)	Area of Ecosite within Vegetation RSA (ha)	Proportion of Ecosite within Vegetation RSA Potentially Affected (%)
Lower Foothills	LFn - marsh	1.30	20.40	6.4
Central Mixedwood	CMWc - Labrador tea-mesic	3.16	56.76	5.6
Central Mixedwood	CMWh - Labrador tea/horsetail	3.71	87.18	4.3
Central Mixedwood	CMWk - rich fen	3.99	97.80	4.1
Lower Foothills	LFd - Labrador tea-mesic	3.00	75.85	4.0
Central Parkland	CPm - rich fen	2.91	84.78	3.4
Dry Mixedwood	DMWk - rich fen	8.26	255.82	3.2
Central Parkland	CPn - marsh	1.11	39.41	2.8

Note: 1 TEM data is unavailable for the segment between Edson and Hinton. See Appendix C of the Vegetation Technical Report of Volume 5C for TEM limitations and Section 9.0 of this volume for details on supplemental surveys.

2 Refer to the TEM Report (Appendix C) of the Vegetation Technical Report of Volume 5C for more information on ecosites.

It is estimated that approximately 70% of the Project Footprint within Alberta crosses non-native lands or land use characterized by anthropogenic activities (*e.g.,* roads, agriculture).

Listed below in Table 7.2.9-6 are the most affect BGC subzone variants in BC whose total area (ha) on the Footprint, when compared to the BGC subzone variant total area (ha) in the Vegetation RSA, is more than 2.75% of the total community. Communities most affected were selected as those with more than 2.75% of the total community located on the Footprint, based on the distribution of values between 0.05% and 3.75%.

These variants occur on moderately to steeply sloping terrain in valleys and lower level plateaus as well as in mid to high level elevations (Lloyd *et al.* 1990). The Cascade and McLennan variants are characterized by seral stands of lodgepole pine, hybrid white spruce, Douglas-fir (McLennan) and subalpine fir (Cascade) with thimbleberry, birch-leaved spirea, black huckleberry and falsebox common in the understory (Lloyd *et al.* 1990). The Moist Warm Engelmann Spruce - Subalpine Fir (ESSFmw) variant is dominated by Engelmann spruce and amabilis fir with white-flowered rhododendron, Sitka valerian and black huckleberry common in the understory (Lloyd *et al.* 2005). The McLennan Dry Hot Sub Boreal Spruce community only occurs along the Hargreaves to Darfield Segment, while the Cascade Moist Warm Montane Spruce variant and the Moist Warm Engelmann Spruce - Subalpine Fir variant occur only along the Black Pine to Hope Segment.

The variant most affected by the Project (3.75%) is the ESSFmw variant found within the high elevations of the ESSF zone in southern and central interior BC. Only 2.76% of the McLennan variant within the Vegetation RSA lies within the Footprint. However, it is also one of the five most common variants within the Vegetation RSA. The McLennan variant consists of shallow, coarse-textured soils and is vulnerable to nutrient deficiency if the forest floor is cleared (BC Ministry of Forests and Range 2007, 2010).

TABLE 7.2.9-6

NATIVE VEGETATION COMMUNITIES MOST AFFECTED BY THE PROJECT IN BRITISH COLUMBIA[1]

BGC Subzones	Variant	Area of Variant within Project Footprint (ha)	Area of Variant within Vegetation RSA (ha)	Proportion of Variant within Vegetation RSA Potentially Affected (%)
Moist Warm Engelmann Spruce - Subalpine Fir	ESSFmw	8.63	231.06	3.75
Moist Warm Montane Spruce	MSmw1 – Cascade	73.69	2,264.26	3.25
Dry Hot Sub-Boreal Spruce	SBSdh1 – McLennan	269.58	9,772.87	2.76

Note: 1 TEM data is unavailable for 24% of the proposed pipeline corridor in BC. See Appendix C of the Vegetation Technical Report of Volume 5C for TEM limitations and Section 9.0 of this volume for details on supplemental surveys.

The mitigation measures described in Table 7.2.9-3 and in the Pipeline EPP (Volume 6B) are expected to effectively address potential effects on the alteration of the most affected vegetation communities identified in Tables 7.2.9-5 and 7.2.9-6 within the Vegetation RSA.

It is anticipated that successful reclamation of the identified ecosites and variants can be achieved by seeding a cover crop for erosion control and weed control in areas where natural regeneration techniques are to be employed. Reduced grubbing within temporary workspace areas, where feasible and utilizing protective matting during winter months to protect from scraping and compacting will also increase the successful restoration of the identified ecosites and variants. Reduced grubbing of plant roots and clearing of shrubby communities and woody vegetation will reduce the loss of forested communities. Limiting vehicle traffic and managing problem vegetation during all construction phases will minimize weeds and invasive species in these areas. The Pipeline EPP of Volume 6B and Table 7.2.9-3 provides detailed mitigation measures.

Specific learnings from the TMX Anchor Loop Project post-construction environmental monitoring (TERA 2013a) relevant to reclamation of the most affected communities include the following.

- Placing restoration signage adjacent to areas that were being actively restored (*e.g.*, riparian areas, sensitive upland sites and where public misuse was anticipated), was effective in educating the public in regards to the sensitivity of the area and Project restoration methods implemented.

- Long-term wind protection structures (*e.g.,* wind fencing), creation of terrain undulations during final clean-up and reclamation and inclusion of wind-tolerant woody plant species within the planting prescription should be considered when planning revegetation in wind-exposed areas.

- Logs with a diameter of no less than 30 cm placed along and approximately perpendicular to slopes were effective in diverting overland water flow, accumulating sediment and providing wind exposure protection to establishing vegetation.

The potential residual effect of the alteration of up to 6.4% of a variant or ecosite is considered to have a negative impact balance. The residual effect is considered to be of low magnitude due to the expectation that the distribution of ecosites and variants will have a detectable difference from pre-construction conditions, but will not affect the viability of the remaining portion of the ecosite or variant. The residual effect is of medium to long-term reversibility since the effect will extend beyond the reclamation phase (Table 7.2.9-4, point 1[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – the alteration of up to 6.4% of an ecosite or variant is confined to the construction right-of-way.

- Duration: short-term – the events resulting in alteration of a variant or ecosite are clearing during construction of the pipeline or maintenance activities (*e.g.,* integrity digs, vegetation management), the latter of which are limited to any 1 year during the operations phase.

- Frequency: periodic – the events resulting in alteration of up to 6.4% of an ecosite or variant (*i.e.*, pipeline construction and maintenance activities) occur intermittently but repeatedly during the operations phase of the Project.

- Reversibility: medium to long-term – depending upon community type and the growth time required for the component species in each affected variant or ecosite (*e.g.,* forb versus tree), the alteration of up to 6.4% of a variant or ecosite is considered reversible in the medium to long-term. The effects of the proposed pipeline on communities like the Lower Foothills Marsh (LFn - Marsh) are expected to be reversible in the medium-term because the component species (*e.g.,* forbs, sedges) in this community tend to have good regeneration success within 10 years. The effects on ecosites and variants like the rich fens (*e.g.,* CMWk – Rich fen) or the Moist Warm Engelmann Spruce – Subalpine Fir (ESSFmw) are expected to be reversible in the long-term (more than 10 years) due to component species that include trees or specific hydrology regimes. Treed wetlands that are cleared for construction often have long-term regeneration periods due to hydrologic alteration resulting from the initial tree removal. When trees are removed from a wetland they can no longer uptake groundwater, and so the local water table rises, increasing the likelihood that the recovering wetland will be a sedge-dominant meadow rather than a treed fen, especially in cases where the trees will be kept mowed on the right-of-way for the life of the operating pipeline. Therefore, the overall alteration of a variant or ecosite along the footprint will persist in the medium to long-term.

- Magnitude: low – the potential alteration of up to 6.4% of an ecosite or variant is considered to be within environmental standards given that best practices, objectives and provincial guidelines are being followed. Permanent loss of an ecosite or variant is not anticipated to result from either the construction or operations of the proposed pipeline. Alteration of up to 6.4% of an ecosite or variant will likely not affect the viability of the remaining parts of the ecosites and variants within the Vegetation RSA. Though the affected vegetation communities will not have the same component species or diversity following construction, the function of these native vegetation communities will remain.

- Probability: high – the proposed pipeline corridor is located on the identified ecosites and variants.

- Confidence: moderate – the assessment of this residual effect is based on incomplete TEM data, but the analysis is informed by past pipeline projects and the professional experience of the assessment team.

Some Disturbance or Alteration of Grassland Communities in the BG BGC Zone

Approximately 158 ha of grassland is predicted to be directly disturbed or altered on the Footprint in the BG BGC Zone, while grassland communities in the LSA may be indirectly altered during construction and operations of the proposed pipeline, which is considered to have a negative impact balance.

Area of grassland was determined through the use of TEM (see Appendix C of the Vegetation Technical Report of Volume 5C). Polygons in the BG BGC with more than 50% grass dominated variants (*i.e.*, BGxh2 and BGxw1) were deemed to be a bunchgrass community polygon and were included in calculating this metric. Any bunchgrass vegetation community polygon intersected by the Vegetation Footprint is considered to be potentially altered. Bunchgrass communities were also mapped in the Vegetation RSA using the same method. The amount of bunchgrass community intersected by the Footprint (approximately 158 ha) is a small component of the amount of bunchgrass community in the Vegetation RSA (approximately 6,372 ha). Approximately 2.5% of bunchgrass communities in the Vegetation RSA are located on the Project Footprint.

The proposed pipeline corridor parallels existing rights-of-way and other linear disturbances to the extent practical. The proposed pipeline corridor intersects the BG BGC Zone at a few locations in the Black Pines to Hope Segment, while avoiding it for most of the pipeline length. The BG BGC Zone is intersected from approximately RK 829.4 to RK 848.8; RK 849.7 to RK 850.8; RK 896.8 to RK 897.0; RK 897.5 to RK 898.5; RK 899.0 to RK 899.1; RK 918.5 to RK 921.4; and RK 922.7 to RK 933.0 for a total of approximately 35 km.

The visual effects of construction on grassland vegetation communities were raised as a concern during Kamloops ESA and Community Workshops. The mitigation measures suggested in Table 7.2.9-3 and in the Pipeline EPP of Volume 6B take visual impact into consideration. Mitigation measures will be implemented before, during and after construction to minimize the residual effects on grassland vegetation communities. Specific mitigation to address visual effects includes:

- the trench will be backfilled as soon as practical (reducing moisture loss in the soil) (Section 8.4 of the Pipeline EPP);
- straw crimping will be conducted on native grassland soils where wind erosion may be problematic. Straw used will be obtained from: the landowner where the straw will be spread; a Certified seed grower; or fields or bales that have been inspected to be free of weeds (Section 8.6.3 of the Pipeline EPP);
- problem vegetation will be managed along the construction right-of-way during all pipeline construction phases (*i.e.*, pre-construction, construction, post-construction environmental monitoring) and the operational phase [Section 12.0 of Appendix C of the Pipeline EPP]; and
- the effectiveness of revegetation efforts during post-construction environmental monitoring will be monitored following construction, keeping in mind visual effects.

Disturbed areas through native grassland segments will be allowed to naturally regenerate. Although areas disturbed during construction and occasional maintenance activities will be allowed to naturally regenerate or revegetate with the appropriate native species, species composition in the disturbed Footprint will likely be altered. The extent of altered vegetation communities will be limited by the implementation of mitigation measures outlined in Table 7.2.9-3 and the Pipeline EPP (Volume 6B) and reclamation measures will speed the recovery.

For the purposes of this assessment, the mechanisms by which alteration of grasslands communities act outside the Footprint (*i.e.*, edge effects) are assumed to vary according to factors of local vegetation and ecology. Furthermore, the indirect alteration of native vegetation has been characterized according to the proximity from existing or proposed disturbance and does not address variation in magnitude of residual effects for areas where native vegetation has been or may be indirectly altered by multiple sources of disturbance.

Alteration of grassland vegetation communities due to competition for light, soil nutrients and moisture may occur while the Footprint is revegetating. However, the establishment of early successional communities during reclamation will resemble revegetation following natural disturbance since the species composition will favor early successional/colonial species, which are adapted for greater competition pressure for light, nutrients and moisture (excepting the competition resulting from weedy non-native species). As a result, changes in competition for light, nutrients and moisture will not measurably contribute to the overall effect of pipeline construction on alteration of native grassland vegetation over the life of the operating pipeline.

Seeding is the preferred method for revegetating the right-of-way, as prescribed in the Reclamation Management Plan, to facilitate the re-establishment of grassland communities. In addition, the effectiveness of bunchgrass restoration measures will be monitored during post-construction environmental monitoring following construction.

The mitigation measures proposed above have been used successfully on other major pipeline construction projects for other sensitive vegetation communities. Following are some examples of revegetation success from other major pipeline construction projects on grassland communities.

Narrowing down of the right-of-way for sensitive communities was successfully conducted during construction at several locations on a large pipeline in the Central Alberta area (Alliance 2000a,b,c). At the South Saskatchewan River, shrubby vegetation important for wildlife was temporarily covered with geotextile pads during construction (Alliance 2000c). In addition, sensitive grasslands with thorny buffaloberry, considered important for wildlife, was ramped over during construction. The thorny buffaloberry was cut low to the ground and the root mat preserved (Alliance 2000c).

In order to protect Wilcox's panicgrass (*Dichanthelium wilcoxianum*) (S1), a rare grass species, during construction of a pipeline project in 2001, the work site was narrowed by approximately 5 m, no grading was allowed and a blade width of sod was salvaged and placed on straw matting. The sod was then replaced and straw from the matting was then spread over the replaced sod. During post-construction environmental monitoring in 2004, approximately 3,000 plants were found (TERA 2004).

The TransCanada Keystone Pipeline Project intersected approximately 120 km of native rangeland, including lands within the Mixedgrass Natural Subregion of Alberta. A management plan was developed and implemented for the project, with the objective of establishing a positive successional trend towards plant communities present prior to construction. Second year post-construction environmental monitoring of the indicated that revegetation of desirable species continues to progress toward meeting the intent of the objective of the management plan (TransCanada Keystone Pipeline GP Ltd. 2012).

The Express Pipeline Ltd. Express Pipeline Project was approximately 435 km in length, most of which was situated in the Grassland Natural Region of Alberta. A long-term post-construction environmental monitoring project was conducted on native prairie lands along the construction right-of-way. Monitoring conducted in the 14th year following construction of the pipeline indicated that native plant communities had re-established on all monitoring sites where natural revegetation had been used (Kestrel Research Inc. and Gramineae Services Ltd. 2011).

Learnings from the TMX Anchor Loop Project (TERA 2013a) relevant to grassland communities of concern include the following.

- Where sufficient native seed cannot be collected on or adjacent to the construction right-of-way or where the volume requirements of certain species (*i.e.*, native grass seed) exceed the capacity for native collection prior to construction, seed may be sourced from commercial seed companies and native seed collectors with documented collection locations within the same or similar Natural Subregion/BGC zone as the project restoration site.
- Seeding of native grass species immediately following topsoil/root zone material replacement allowed for plant germination and emergence prior to soil crusting and at a time when establishing grass plants are able to compete with weed seedlings.

- Hydro-seeding with the use of a tackifier is an effective method of seeding areas with difficult access, when rapid vegetation establishment is required (aesthetic values) and where there is moderate to high risk of soil erosion due to wind or water on sloping terrain and/or erodible soils.

- Aerial seeding is an effective and efficient method of broadcast seeding the disturbed construction right-of-way where landscape features, wet soil conditions and a limited seeding window may restrict the use of other seeding methods.

- Bulldozer track packing (soil imprinting perpendicular to the slope) of the construction right-of-way during final clean-up allowed for the establishment of soil microsites that facilitated the capture of broadcast grass seed and precipitation, reduced the formation of rills from soil water erosion and promoted the establishment of vegetation cover.

Application of herbicides to grassland vegetation communities during all pipeline construction phases (*i.e.*, pre-construction and construction) and operations phase (*i.e.*, post-construction environmental monitoring) could cause an alteration in the composition of the vegetation community, depending on the area, quantity and specificity of herbicide applied. However, the use of best practices in weed control and vegetation management reduces the potential for herbicide drift or effects to unintended areas or species. Vegetation management conducted by mechanical means (*i.e.*, cutting or mowing) will be favoured; if vegetation management by chemical means is the only feasible method it should be conducted with equipment that ensures the specificity of the application.

During regular maintenance and operations activities, incidental ground inspections for problem vegetation along the construction right-of-way may be conducted to determine the extent (percent cover, composition, distribution, location of infestations) of problem vegetation (*i.e.*, presence of mature brush and trees, and weeds). Areas of new infestations, recommended treatment sites and adjacent landowner concerns will also be identified and documented during monitoring. To assist monitoring efforts, the baseline data collected during the pre-construction weed survey and the results of the post-construction environmental monitoring program will assist in establishing thresholds and determining if objectives of the Weed and Vegetation Management Plan are being met (Section 12.0 of Appendix C of the Pipeline EPP [Volume 6B]).

If the bunchgrass community cannot be avoided, then a narrowed strip of the bunchgrass community will be disturbed resulting in some alteration of the community, resulting in a negative impact balance. Based on the assessment of the bunchgrass vegetation communities that will be encountered during construction, the mitigation measures described above are considered to be appropriate and applicable to the Project. Consequently, the most acute and likely residual effects of pipeline construction on grassland vegetation communities are confined to the Vegetation LSA, are reversible in the medium to long-term and of medium magnitude (Table 7.2.9-4, point 1[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Vegetation LSA – although alteration of grasslands is generally confined to the disturbed portion of the construction right-of-way, potential changes in hydrology and species composition may extend beyond the pipeline right-of-way.

- Duration: short-term – the events resulting in alteration of grassland community vegetation are construction of the pipeline or maintenance activities (*e.g.,* integrity digs, vegetation management), the latter of which are limited to any 1 year during the operations phase.

- Frequency: periodic – the events resulting in alteration of grassland community vegetation (*i.e.*, construction of the pipeline and maintenance activities) will occur intermittently but repeatedly during the operations phase of the Project.

- Reversibility: medium to long-term – establishing a cover of native grassland species or a cover crop species will occur over the medium-term, but greater species diversity, including the establishment of some grassland species (*i.e.*, fescue if it is present within the communities encountered), may occur more slowly (long-term). Weed introduction can take years of management to remediate, depending on the non-native species (*i.e.*, non-native grasses) and the specificity of the herbicide.

- Magnitude: medium – the proposed pipeline corridor is located adjacent to existing disturbances to the extent practical and the construction of the pipeline will result in the clearing of approximately 158 ha of grassland vegetation, which is approximately 2.5% of all bunchgrass communities in the Vegetation RSA. The Project will contribute to a combined loss or alteration of native grassland vegetation, however, there are no standards or thresholds that would otherwise indicate loss or alteration of native grassland vegetation is unacceptable given that best practices, objectives and provincial guidelines are being followed.

- Probability: high – the proposed pipeline corridor crosses native grassland vegetation in the BG BGC Zone.

- Confidence: moderate – confidence would be high based on past pipeline projects, the assessment team's understanding of the effects and mitigation, but land access in the BG BGC was low and TERA was unable to survey many of grassland communities in the area, resulting in moderate overall confidence.

Some Disturbance or Alteration of a Rare Ecological Community, if Avoidance is Not Practical and Mitigation Measures Do Not Completely Protect a Site

Rare plant surveys were conducted during the growing season in 2013 on lands where access was granted as a component of the vegetation surveys. Supplemental ground-based rare plant surveys are planned to be conducted prior to construction on any new lands due to rerouting or where rare ecological communities were identified that need verification; see Section 9.0 for more details regarding supplemental surveys. In the event that additional rare ecological communities are identified in the Footprint during supplemental surveys, mitigation will be determined using the Rare Ecological Community and Rare Plant Population Management Plan (Section 5.0 of Appendix C of the Pipeline EPP [Volume 6B]).

During the 2013 rare plant surveys, 25 occurrences of ACIMS and BC CDC-listed rare ecological communities (12 distinct rare ecological communities) were observed, including wetland communities of concern, as well as one unique ecological community not listed by ACIMS or the BC CDC. Protection measures and environmental management techniques for rare ecological communities are provided in Appendix C of the Pipeline EPP of Volume 6B. Mitigation measures for rare ecological communities generally fall into categories of avoidance, (*e.g.,* realignment, change of work side, narrowing), reducing disturbance (*e.g.,* narrowing, adjusting workspaces, ramping/matting over) and alternative construction/reclamation techniques (*e.g.,* salvaging seed or sod, plant propagation, transplanting component species, separate root zone material salvage, delayed clearing, access management) (see the Vegetation Technical Report of Volume 5C and Appendix C of the Pipeline EPP [Volume 6B] for more details). These proposed mitigation measures have been used previously on other major pipeline construction projects with good success. Some examples are provided below.

Narrowing down the right-of-way for sensitive communities was successfully conducted during construction at several locations on a pipeline project in the Central Alberta area (Alliance 2000a,b). At the South Saskatchewan River, shrubby vegetation important for wildlife was temporarily covered with geotextile pads during construction (Alliance 2000c). In addition, sensitive grasslands with thorny buffaloberry, considered important for wildlife, was ramped over during construction. The thorny buffaloberry was cut low to the ground and the root mat preserved (Alliance 2000c). Covering a rare ecological community with geotextile or ramping over are measures that are expected to have higher success during construction in frozen conditions when plants are dormant and snow can be used to protect the vegetation.

During a pipeline project in the Dawson Creek area of BC, several aspen/thimbleberry/wild sarsaparilla communities (S2S3) were observed on the right-of-way. The locations were staked off and the right-of-way was also narrowed to the greatest extent feasible, in the vicinity of these communities. The proposed mitigation for these rare communities also included avoidance of grubbing, and where vehicle travel occurred, matting and temporary travel surfaces were used to limit vehicular disturbance. Post-construction environmental monitoring found that the communities had experienced minimal impact. Avoidance during construction by narrowing the right-of-way was found to have resulted in a near pre-construction level of species composition and abundance (TERA 2012g).

Learnings from the TMX Anchor Loop Project (TERA 2013a) pertinent to rare ecological communities (including wetland communities of concern) include the following.

- Natural regeneration is an effective means of revegetation in wetlands where construction disturbance is limited to the trench area and where accurate separation and replacement of trench materials is achieved.
- In wetlands, transplanting of sedge and bulrush species from local undisturbed donor sites into construction disturbed areas proved to be an effective method of revegetation as transfers established and spread within their respective habitats.

Mitigation is developed with a number of factors taken into account that include, however, are not limited to:

- component species;
- community size;
- rarity;
- construction timing;
- location of the community with respect to the proposed right-of-way;
- primary mode of component species reproduction;
- habitat and proximity of available habitat; and
- past mitigation success (of the community or similar communities).

Based on the assessment of the rare ecological communities that will be encountered during construction, the mitigation measures described above are considered to be appropriate and applicable to the Project. If mitigation measures do not completely protect the site, a disturbance or alteration of a portion of the community may occur and is considered to have a negative impact balance. For example, if a narrowed strip of the S1, S2 or S3 community will be disturbed it would result in some alteration of the community. In addition, temporarily covering of the site and implementing construction traffic restrictions may not completely protect the community. By basing mitigation on community ranking and abundance, in addition to its location on the construction right-of-way and the community type, any alteration of the local community, particularly S1 communities, will be reduced to a level such that the local community is not placed at risk. Consequently, the residual effect of pipeline construction on rare ecological communities and unique communities are of medium magnitude (Table 7.2.9-4, point 1[e]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – the potential disturbance or alteration of a rare ecological community is confined to the construction right-of-way.
- Duration: short-term – the events resulting in potential disturbance or alteration of a rare ecological community are construction of the pipeline or maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events resulting in potential disturbance or alteration of a rare ecological community (*i.e.*, construction of the pipeline and maintenance activities) occur intermittently, however, repeatedly during the operations phase of the Project.
- Reversibility: medium to long-term – depending on the component species (*e.g.,* western redcedar and amabilis fir [amabilis fir - western redcedar/devil's club community] will take years to grow to mature trees, compared to common cattails [common cattail marsh] or beaked sedge [beaked sedge marsh] which can recolonize or re-establish in one growing season if the seed bank and habitat is available).

- Magnitude: medium – the potential disturbance or alteration of a rare ecological community is of medium magnitude since the effect is still within environmental standards given that best practices, objectives and provincial guidelines are being followed. Returning the footprint to an equivalent land capability and regrowth of a rare ecological community could take years, as discussed under reversibility (medium).

- Probability: high – there are 25 rare ecological communities identified within the proposed pipeline corridor during the vegetation surveys in 2013 and they may be traversed by the Footprint.

- Confidence: high – based on past pipeline projects, the professional experience of the assessment team and the results of post-construction environmental monitoring.

Indirect Effects to Rare Ecological Communities

With proper implementation of the industry-accepted standard mitigation practices that are proposed, disruption of surface flow patterns and light levels following construction or maintenance activities are expected to be minor along the proposed pipeline corridor. However, construction and maintenance activities (*e.g.*, integrity digs) may contribute to some localized alteration of light levels and natural surface drainage patterns until trench settlement is complete and seeded vegetation has matured. The impact balance of this potential residual effect is considered negative since it could alter the moisture regime and light levels.

Indirect alteration of rare ecological communities adjacent to the Footprint may occur due to soil erosion. Some rare ecological communities may be more susceptible to erosion than others. For example, the white birch – ground-pine - stiff club-moss (*Betula papyrifera/Lycopodium obscurum - Lycopodium annotinum*) woodland community identified during 2013 vegetation surveys is typically located in a midslope position where soils are exposed but potentially have a high litter cover. The location of the community on a slope and on exposed soils increases the potential for erosion if the litter cover is removed. Since the areas with greatest erosion risk will be seeded with native species or an annual cover crop (or otherwise stabilized with erosion control blankets, coir matting, woody slash, or straw crimping [Section 6.0 of Appendix C and Section 8.6.3 of the EPP]), the indirect alteration of native vegetation as a result of erosion will not measurably contribute to the overall effect of pipeline construction on the alteration of rare ecological communities.

Increased distance of light penetration due to clearing will result in an indirect alteration of native vegetation (*i.e.*, the native species making up the rare ecological community). For example, the western redcedar – sitka spruce/skunk cabbage (*Picea sitchensis/Lysichiton americanus*) community identified during the 2013 vegetation surveys is a forested community, characterized by low light penetration due to dense tree canopy. If part of the community is cleared, the light penetrating to the understory will change the species composition along the edges of the community where clearing occurred. However, this effect will not substantially contribute to the alteration of native vegetation beyond the effects detailed in relation to the clearing of native vegetation. Additionally, during the course of reclamation, as revegetation progresses, light penetration will generally decrease over time.

Given that indirect effects are, in part, caused by disturbance to vegetation structure associated with clearing activities, allowing disturbed areas to naturally revegetate may not alleviate indirect effects where vegetation management is conducted or long-term persistence of the disturbance exists. Consequently, indirect effects to vegetation are expected to persist until the pre-existing vegetation composition and structure is restored for the Footprint.

During the construction and operations of the pipeline, there will be a decrease in woody species richness and abundance due to clearing within the footprint, but due to edge effects there may be increases in woody species richness and abundance in areas adjacent to the Footprint. Forb and graminoid species richness and abundance will increase following construction as natural vegetation regenerates.

Alteration of native vegetation due to competition for light, soil nutrients and moisture may occur while the Footprint is revegetating. However, the establishment of early successional communities following construction will resemble revegetation following natural disturbance since the species composition will favor early successional/colonial species, which are adapted for greater competition pressure for light, nutrients and moisture (excepting the competition resulting from weedy non-native species).

The post-construction environmental monitoring program will identify any locations with altered drainage patterns (*e.g.,* ponded water) and remedial work will be conducted. Once pre-construction hydrology regimes are returned to a site, regeneration or revegetation of rare ecological communities will be more likely.

The effect of construction on adjacent rare ecological communities is deemed to have a negative impact balance. This residual effect is limited to the Vegetation LSA, reversible in the medium to long-term and of low magnitude since the proposed pipeline corridor parallels other pipeline rights-of-way and disturbance for 89% of its length (Table 7.2.9-4, point 1[e]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Vegetation LSA – although alteration of rare ecological communities is generally confined to the construction right-of-way, potential changes in hydrology, light levels and species composition may extend beyond the pipeline right-of-way.
- Duration: short-term – the events resulting in alteration of adjacent rare ecological communities are clearing during construction of the pipeline or maintenance activities (*e.g.,* integrity digs, vegetation management), the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events resulting in alteration of adjacent rare ecological communities (*i.e.*, pipeline construction and maintenance activities) occur intermittently but repeatedly during the operations phase of the Project.
- Reversibility: medium to long-term – it may take more than 1 year plus adequate precipitation levels in order for the trench crown to settle and natural drainage patterns to be restored, and it will take several years for vegetation to grow back to former heights, which will prevent increased light from reaching surrounding plants in the ecological community.
- Magnitude: low – the proposed pipeline corridor is located adjacent to existing disturbances to the extent practical and the residual effects are detectable but are still considered to be within environmental standards given that best practices, objectives and provincial guidelines are being followed.
- Probability: high – the proposed pipeline corridor is adjacent to native vegetation with high potential to support rare ecological communities, including forested areas that will be affected by clearing vegetation during construction.
- Confidence: moderate – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on Vegetation Communities of Concern

This subsection presents an evaluation of combined effects considering those residual environmental effects on vegetation communities of concern that are likely to occur. The potential residual environmental effects related to vegetation communities of concern evaluated in Section 7.2.9.6 (Table 7.2.9-4, points 1[a] to 1[e]), are of high probability, and consequently, were considered in the evaluation of combined effects on the vegetation communities of concern indicator.

The residual effects included:

- alteration of approximately 2,058 ha of native vegetation;
- alteration of up to approximately 6.4% of a variant or ecosite phase;
- some disturbance or alteration of grassland communities in the BG BGC Zone;
- some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site; and

- if rare ecological communities are located adjacent to the construction right-of-way they may be indirectly affected by changes in hydrology or light levels.

The adverse effects identified contribute to combined effects on vegetation communities of concern encountered along the proposed pipeline corridor. The reversibility of the combined effects is considered medium to long-term depending on the species, the land use and the mitigation measures. However, the magnitude of the combined effects on the vegetation communities of concern indicator is considered to be low to medium since the combined effect is likely to be reduced by implementation of mitigation strategies for each of the residual effects (Table 7.2.9-4, point 1[f]). In addition, effects on vegetation communities of concern will be monitored as part of the post-construction environmental monitoring program (Volume 6A). A summary of the rationale for all of the significance criteria of combined effects on vegetation communities of concern is provided below.

- Spatial Boundary: Vegetation LSA – combined effects on the vegetation communities of concern indicator may extend beyond the pipeline right-of-way to the Vegetation LSA.
- Duration: short-term – the events contributing to the combined effects on the vegetation communities of concern indicator are clearing during construction of the pipeline or maintenance activities (*e.g.,* integrity digs, vegetation management), the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events contributing to the combined effects on the vegetation community of concern indicator (*i.e.*, construction of the pipeline) are generally confined to the construction period but may occur intermittently but repeatedly during the operations phase of the Project.
- Reversibility: medium to long-term – depending upon the associated land use and the growth time required for component species in each affected area (*e.g.,* forb versus tree), changes to the composition of vegetation communities of concern are considered reversible in the medium to long-term.
- Magnitude: low to medium – combined effects on the vegetation community of concern indicator are anticipated to be largely mitigated during construction and post-construction environmental monitoring. The proposed pipeline corridor is located adjacent to existing disturbances for 89% of the length and the construction of the pipeline will result in the clearing of approximately 2,058 ha of native vegetation, which is considered to be within environmental standards given that best practices, objectives and provincial guidelines are being followed. Permanent loss of native vegetation is not anticipated to result from either the construction or operations of the proposed pipeline and most weed issues can be resolved during post-construction environmental monitoring (low). However, returning the Footprint to an equivalent land capability could take years, as discussed under loss of native vegetation and regeneration of a rare ecological community could take years (medium).
- Probability: high – the Footprint crosses native vegetation, rare ecological communities, grassland communities and is located adjacent to native vegetation with a high potential to support rare ecological communities.
- Confidence: moderate – based on available research literature, data pertinent to previous vegetation communities of concern encountered along the existing TMPL right-of-way and the professional experience of the assessment team.

<u>Vegetation Indicator – Plant and Lichen Species of Concern</u>

The following provides the evaluation of significance of potential residual effects on the plant and lichen species of concern indicator.

Some Disturbance or Alteration of a Rare Plant Occurrence, if Avoidance is Not Practical and Mitigation Measures Do Not Completely Protect a Site

During the 2013 rare plant surveys, which were a component of the vegetation surveys, 154 occurrences of ACIMS and BC CDC-listed rare plant species were observed, including 20 liverwort populations (8 unique species), 11 moss populations (7 unique species) and 123 vascular plant populations

(39 unique species) (see the Vegetation Technical Report of Volume 5C). Protection measures and environmental management techniques for rare plants are provided in Appendix C of the Pipeline EPP of Volume 6B. Mitigation measures for rare plant species generally fall into categories of avoidance, (*e.g.,* realignment, change of work side, narrowing), reducing disturbance (*e.g.,* narrowing, adjusting workspaces, ramping/matting over) and alternative construction/reclamation techniques (*e.g.,* salvaging seed or sod, plant propagation, transplanting, separate strippings salvage, delay clearing, access management) (see the Vegetation Technical Report of Volume 5C for more details). These proposed mitigation measures have been used previously on other major pipeline construction projects with good success. Some examples are provided below.

Golden saxifrage (*Chrysosplenium iowense*) (S2S3) was observed along the proposed corridor for a large pipeline project in Alberta and BC. During construction, in the winter of 1999/2000, the salvaged topsoil from the vicinity of this population was stored separately and replaced. During the second year of the post-construction environmental monitoring in 2001, plants were observed both on and off of the right-of-way (Alliance 2002).

Turned sedge (*Carex retrorsa*) (S2S3) was observed along a proposed pipeline right-of-way near Whitecourt (Alliance 2000b). The area was ramped over by cutting and laying down willows, covering them with geotextile and then ramping with subsoil. Upon completion of construction, the ramp was removed. During post-construction environmental monitoring in 2001, the turned sedge was found in very large numbers both on and off the right-of-way (Alliance 2002).

During a pipeline project, conic liverwort (*Conocephalum conicum,* S2) was observed on the pipeline right-of-way. The conic liverwort population location was staked off and the right-of-way was narrowed to the greatest extent feasible. The proposed mitigation for this population also included recontouring drainage bed and banks. The resulting post construction monitoring found that the conic liverwort population had experienced minimal impact (TERA 2012g).

Prior to construction of TMX Anchor Loop pipeline, Mingan grape fern (*Botrychium minganense*) (SU) plants were transplanted off the right-of-way and temporary workspace into immediately adjacent areas with similar habitat features. In 2010, the plant was observed at the transplant location and the transplant was considered to be successful (TERA 2011a).

Prior to construction of a proposed pipeline in northern BC in 2002, western Jacob's-ladder (*Polemonium occidentale* ssp. *occidentale*) (S2S3) plants were transplanted off the right-of-way and temporary workspace into immediately adjacent areas with similar habitat features. During the third year of post-construction environmental monitoring, the plants were persisting at most locations and the population was considered to be stable (TERA 2005).

During a pipeline project, yellow collar moss (*Splachnum luteum,* S2) was observed on the pipeline right-of-way. The yellow collar moss population was transplanted off right-of-way and no further monitoring was deemed warranted (TERA 2012g).

Rare plant surveys for the Project were conducted during the growing season in 2013 on lands where access was granted as a component of the vegetation surveys. Supplemental rare plant surveys are planned prior to construction on any new areas due to rerouting; see Section 9.0 for more details regarding supplemental surveys. In the event that additional rare plant species are identified in the Footprint during supplemental surveys, mitigation will be determined using the Rare Ecological Community and Rare Plant Population Management Plan (Section 7.0 of Appendix C of the Pipeline EPP [Volume 6B]). In the event that additional rare plant species are identified on or within 30 m of the construction right-of-way during construction, refer to the Rare Ecological Community and Rare Plant Population Discovery Contingency Plan (Section 7.0 of Appendix B of the Pipeline EPP [Volume 6B]).

Based on the assessment of the rare plants with potential to be encountered during construction, the mitigation measures described above are considered likely to be appropriate and applicable to the Project. However, if mitigation measures do not completely protect the site, a disturbance or alteration of a portion of the population or community may occur. Mitigation is developed with a number of factors taken into account that include, however, are not limited to:

- species;
- population size;
- rarity;
- growth form of the plant (*i.e.*, annual, biennial, perennial);
- construction timing;
- location of the population with respect to the proposed footprint;
- primary mode of species reproduction;
- mode and magnitude of propagule dispersal;
- habitat and proximity of available habitat; and
- past mitigation success (of the species or similar species).

By basing mitigation on these factors, any disturbance or alteration of a rare plant population, particularly those ranked S1, would be reduced to a level such that the population is not placed at risk (Table 7.2.9-4 point 2[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – the potential disturbance or alteration of a rare plant population is confined to the construction right-of-way.
- Duration: short-term – the events resulting in potential disturbance or alteration of a rare plant population are clearing during construction of the pipeline or maintenance activities (*e.g.,* integrity digs, vegetation maintenance), the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing potential disturbance or alteration of a rare plant population (*i.e.*, construction of the pipeline and maintenance activities) occur intermittently but repeatedly at some locations during the operations phase of the Project.
- Reversibility: medium to long-term – depending on the species, the construction method (*e.g.,* narrowing the right-of-way or matting over, compared to transplanting) and the landscape. For example, golden saxifrage has been documented to revegetate previously disturbed rights-of-way within a few years following post-construction environmental monitoring (Alliance 2002) as long as the landscape is recontoured and the hydrology returns to pre-construction conditions (medium-term). Stalked moonwort and Michigan moonwort, were found along the proposed pipeline corridor in open, sandy areas with lodgepole pine. The area these plants inhibit will be prone to erosion and their associated species (lodgepole pine) will take more than 10 years to grow back (long-term).
- Magnitude: medium – the potential disturbance or alteration of a rare plant population is of medium magnitude since the effect is considered to be within environmental standards given that best practices, objectives and provincial guidelines are being followed.
- Probability: high – there are 146 rare plant populations identified within the proposed pipeline corridor that were identified during the rare plant surveys in 2013. It is likely that rare plant populations will be found within the Footprint.
- Confidence: high – based on past pipeline projects, the experience of the assessment team and the results of the rare plant surveys.

Some Disturbance or Alteration of a Rare Lichen Occurrence, if Avoidance is Not Practical and Mitigation Measures Do Not Completely Protect a Site

During the 2013 rare plant surveys, which were a component of the vegetation surveys, 14 ACIMS and BC CDC-listed rare lichen populations (11 unique species) were observed. Protection measures and environmental management techniques for rare lichens are provided in Appendix C of the Pipeline EPP (Volume 6B). Mitigation measures for rare lichen species generally fall into categories of avoidance, (*e.g.* realignment, change of work side, narrowing), reducing disturbance (*e.g.,* narrowing, protective matting, snow cover in winter) and alternative construction/reclamation techniques (*e.g.,* relocation of substrates, transplanting of thalli or peds, inoculation using vegetative fragments) (see the Vegetation Technical Report of Volume 5C for more details). These proposed mitigation measures have been used previously on other major pipeline construction projects with good success, but in general, fencing and avoiding is the mitigation that has the greatest likelihood of success, as compared to transplanting, and is the preferred conservation strategy.

Avoidance was highly successful in protecting rare species along the TMX Anchor Loop Project. Of the 82 sites monitored in 2010 where fence and avoid procedures were employed, 77 had retained the rare lichen species targeted for mitigation (TERA 2011a).

Based on the assessment of the rare lichens with potential to be encountered during pipeline construction, the mitigation measures described above are considered likely to be appropriate and applicable to the Project. However, if mitigation measures do not completely protect the site, a disturbance or alteration of a portion of the population may occur. Mitigation is developed with a number of factors taken into account that include, but are not limited to:

- species;
- population size;
- rarity;
- construction timing;
- location of the population with respect to the proposed footprint;
- preference substrate and proximity of available substrates; and
- past mitigation success (of the species or similar species).

By basing mitigation on these factors, any disturbance or alteration of a rare lichen population, particularly those ranked S1, would be reduced to a level such that the population is not placed at risk.

Supplemental ground-based rare plant surveys are planned prior to construction; see Section 9.0 for more details regarding supplemental surveys. In the event that additional rare lichen species are identified within the Footprint during supplemental surveys, mitigation will be determined using the Rare Ecological Community and Rare Plant Population Management Plan (Section 7.0 of Appendix C of the Pipeline EPP [Volume 6B]). In the event that additional rare plant species are identified on or within 30 m of the construction right-of-way during construction, refer to the Rare Ecological Community and Rare Plant Population Discovery Contingency Plan (Section 7.0 of Appendix B of the Pipeline EPP [Volume 6B]).

The effect of construction on rare lichen populations is deemed to have a negative impact balance. This residual effect is limited to the Vegetation Footprint, reversible in the short to medium-term and of medium magnitude since the proposed pipeline corridor parallels other pipeline projects and disturbance for 89% of its length (Table 7.2.9-4, point 2[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – the potential disturbance or alteration of a rare lichen population is confined to the construction right-of-way.

- Duration: short-term – the events resulting in potential disturbance or alteration of a rare lichen population are construction of the pipeline or maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year during the operations phase.

- Frequency: periodic – the events resulting in potential disturbance or alteration of a rare lichen population (*i.e.*, construction of the pipeline and maintenance activities) occur intermittently but repeatedly during the operations phase of the Project.

- Reversibility: short to medium-term – depending on the species and the mitigation measures applied. Based on post-construction environmental monitoring results from TMX Anchor Loop, effects on rare lichens were generally resolved in 3 to 5 years (*i.e.,* it was obvious in 3 to 5 years of post-construction environmental monitoring whether the population would survive or not) (TERA 2011a).

- Magnitude: medium – the potential disturbance or alteration of a rare lichen population is of medium magnitude since the effect is still within environmental standards given that best practices, objectives and provincial guidelines are being followed.

- Probability: high – there are six rare lichen populations identified within the proposed pipeline corridor during the rare plant surveys in 2013 and it is likely that rare lichen populations will be found within the Project footprint.

- Confidence: high – based on past pipeline projects, the experience of the assessment team and the results of the rare plant surveys.

Indirect Effects to Rare Plant and Lichen Sub-Populations

With proper implementation of the industry-accepted standard mitigation practices that are proposed, disruption of surface flow patterns and light levels following construction or maintenance activities is expected to be minor along the proposed pipeline corridor. However, construction activities may contribute to some localized alteration of light levels and natural surface drainage patterns until trench settlement is complete and vegetation has matured. The impact balance of this potential residual effect is considered negative since it could alter the moisture regime and light levels. In addition, dust deposition and the chemicals used to suppress dust have the potential to impact rare plants and lichens.

Indirect alteration of rare plant and lichen populations adjacent to the Project may occur due to soil erosion. Since the areas with greatest erosion risk will be seeded with native species or an annual cover crop (or otherwise stabilized with mulch, straw, crimping), the indirect alteration of native vegetation as a result of erosion will not measurably contribute to the overall effect of the Project on the alteration of rare plant populations.

Increased distance of light penetration due to clearing will result in an indirect alteration of native vegetation (*i.e.*, the native species making up the habitat for rare plant populations). For example, western oak fern, goldthread and a rare lichen (*Usnea quasirigida*), identified during the 2013 rare plant surveys, are only found in forested communities characterized by low light penetration due to dense tree canopy and a specific amount of humidity. If part of the treed community is cleared, the light penetrating to the understory will change the species composition along the edges of the community where clearing occurred and the increased air flow will alter humidity within the area. However, this effect will not substantially contribute to the alteration of native vegetation beyond the effects detailed in relation to the clearing of native vegetation. Additionally, during the course of reclamation, as revegetation progresses, light penetration and air flow will generally decrease over time.

Given that indirect effects are, in part, caused by disturbance to vegetation structure associated with clearing activities, allowing disturbed areas to naturally revegetate may not alleviate indirect effects where vegetation management is conducted or long-term persistence of the disturbance exists. Consequently, indirect effects to rare plant and lichen populations are expected to persist until the pre-existing vegetation composition and structure is restored for the Footprint.

During construction and operations of the pipeline, vehicle traffic will increase dust deposition onto native vegetation adjacent to the Footprint which could include rare lichen populations. Use of dust suppressants has the potential to affect both plant and lichen species. During reclamation, dust due to Project traffic could also result in minor effects to rare lichens located adjacent to the right-of-way.

Alteration of native vegetation due to competition for light, soil nutrients and moisture may occur while the Footprint is revegetating. However, the establishment of early successional communities following construction will resemble revegetation following natural disturbance since the species composition will favor early successional/colonial species, which are adapted for greater competition pressure for light, nutrients and moisture (excepting the competition resulting from weedy non-native species).

Many rare species inhibit areas with specific hydrology and light regimes. If hydrology of an area is altered, rare plant or lichen species located adjacent to the construction right-of-way may be affected. For example, golden saxifrage requires moist but not submerged substrate to grow on. The post-construction environmental monitoring program will identify any locations with altered drainage patterns (*e.g.,* ponded water) and remedial work will be conducted. Consequently, the residual effect is reversible in the short to long-term. This residual effect is of low magnitude since the proposed pipeline corridor parallels other pipeline projects and disturbance for 89% of its length (Table 7.2.9-4, point 2[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Vegetation LSA – although alteration of rare plant and lichen populations is generally confined to the disturbed portion of the construction right-of-way, potential changes in hydrology, dust and light levels may extend beyond the pipeline right-of-way.
- Duration: short-term – the events resulting in alteration of rare plant and lichen populations are clearing during construction of the pipeline or maintenance activities (*e.g.,* integrity digs, vegetation management), the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events resulting in alteration of rare plant and lichen populations via disruption of drainage patterns and altered light levels (*i.e.*, construction of the pipeline and maintenance activities) occur intermittently but repeatedly during the operations phase of the Project.
- Reversibility: short to long-term – it may take more than 1 year plus adequate precipitation levels in order for the trench crown to settle and natural drainage patterns to be restored and along extra temporary workspace it will take years for vegetation to grow back to former heights, which is what affects the light levels reaching surrounding plants. The full right-of-way will be maintained free of higher growing vegetation until abandonment (long-term). The potential for effects from dust and dust suppressants exist until construction activities are completed.
- Magnitude: low – the proposed pipeline corridor is located adjacent to existing disturbances to the extent practical. Residual effects are detectable, but are still considered to be within environmental standards given that best practices, objectives and provincial guidelines are being followed.
- Probability: high – the proposed pipeline corridor crosses forested vegetation communities that provide potential habitat for rare plant and lichen species and the forested vegetation will be affected by clearing activities during construction.
- Confidence: high – based on past pipeline projects, the experience of the assessment team and the results of the rare plant surveys.

Indirect Effects to Vegetation Species at Risk

Federally-listed vegetation species at risk (*i.e.*, designated by COSEWIC or on *Species at Risk Act* Schedule 1) identified as having potential to occur along the proposed pipeline segments are described in Section 4.3 of the Vegetation Technical Report (Volume 5C). For vegetation, species at risk are assessed together as an indicator group, due to the number of at risk species and their different, and often not well understood, habitat requirements.

The potential effects associated with the construction and operations of the proposed pipeline on vegetation species at risk were identified by the assessment team based on element occurrence records (within the Vegetation RSA) from ACIMS (2012) and the BC CDC (2013), as well as Candidate Critical Habitat mapping (Environment Canada 2013d).

TEK participants did not identify any concerns related to vegetation species at risk along any of the pipeline segments during the 2013 vegetation surveys, although they did relate that several areas along the entire proposed pipeline corridor were used for gathering medicinal plants, plants with utilitarian purposes and edible plants including berries.

The proposed pipeline corridor has been aligned to reduce disturbance to native vegetation by paralleling existing linear disturbances to the extent practical and by utilizing workspace on adjacent existing rights-of-way. Additional mitigation measures recommended in the Vegetation Technical Report (Volume 5C) to reduce the potential effects of pipeline construction and operations on vegetation species at risk have been incorporated into Table 7.2.9-4. These measures were developed in accordance with Trans Mountain standards and the provincial and federal regulatory guidelines listed in Table 7.2.9-4.

During the 2013 vegetation surveys, one species listed on Schedule 1 of the *Species at Risk Act* was potentially observed: Mexican mosquito fern (*Azolla mexicana*). This species is designated as Threatened by *Species at Risk Act* and COSEWIC, is globally ranked as G5. In BC it is ranked as S2 and is on the Red list. This potential occurrence requires confirmation; see Section 9.0 for details on supplemental surveys.

The *Species at Risk Act* states that no person shall destroy any part of the habitat of a species listed as Endangered or Threatened and that no species listed as Endangered or Threatened can be damaged or destroyed. Section 97 of *SARA* states that this is an indictable offense for which there are monetary penalties. For species designated as Endangered or Threatened on Schedule 1, a Recovery Strategy must be provided within 1 year of their designation. Critical habitat is defined in a species-specific Recovery Strategy and is based on the best available information. Mexican mosquito fern was last assessed by COSEWIC in 2008 and the recovery strategy is not yet finalized (Environment Canada 2013c).

Candidate critical habitat for whitebark pine occurs within 1 km of the proposed pipeline corridor in two locations; one along the Hargreaves to Darfield Segment; and the other along the Black Pines to Hope Segment (Environment Canada 2013d). There is proposed critical habitat for toothcup meadow-foam overlapping the proposed pipeline corridor in the Black Pines to Hope Segment (Environment Canada 2013d). Candidate critical habitat does not yet exist for Vancouver Island beggarticks, Haller's apple moss, tall bugbane, Mexican mosquito fern or peacock vinyl lichen (Environment Canada 2013c).

Protection measures and environmental management techniques for vegetation species at risk are provided in Appendix C of the Pipeline EPP of Volume 6B. Mitigation measures for vegetation species at risk should be those of avoidance (*e.g.* realignment, change of work side, narrowing). See the Vegetation Technical Report of Volume 5C for more details.

During pre-construction surveys of a large pipeline project, small-flowered sand verbena (*Trypterocalyx micranthus*) was located on the proposed right-of-way (Enbridge Pipelines Inc. 2011). Small-flowered sand verbena is listed as Endangered by COSEWIC and is protected under federal legislation by the *SARA* (Environment Canada 2013c). By extending the horizontal directional drill of the South Saskatchewan River, the population was avoided (TERA 2011c).

In southeastern Alberta the small-flowered sand verbena (*Tripterocalyx micranthus*), *SARA*-listed as Endangered, was identified and avoided during the routing of a small-diameter pipeline gathering system (Fryer pers. comm.). A targeted species survey was conducted of the appropriate habitat for the ephemeral annual within 300 m of the gathering system.

Rare plant surveys were completed during the growing season in 2013 for over 25% of the proposed pipeline corridor length. Supplemental rare plant surveys are planned prior to construction on new lands totaling less than 7% of the proposed pipeline corridor, as well as in areas where land access was not available in 2013 or where rare plant species were identified that need verification (see Section 9.0). The potential occurrence of Mexican mosquito fern will be confirmed during supplemental surveys. In the event that additional species at risk are identified in the Footprint during supplemental surveys, mitigation will be determined using the Rare Ecological Community and Rare Plant Population Management Plan (Section 7.0 of Appendix C of the Pipeline EPP).

Based on the assessment of the vegetation species at risk with potential to be encountered during construction, the mitigation measures described above are considered likely to be appropriate and applicable to the Project. Due to the restrictions around damaging or destroying *Species at Risk Act*-listed plant or lichen species, any populations should be avoided by construction and operations, so there should not be any disturbance or alteration of a portion of a population.

A summary of the rationale for all of the significance criteria is provided below (Table 7.2.9-4, point 2[d]).

- Spatial Boundary: Vegetation LSA – the potential disturbance or alteration of a vegetation species at risk would not occur on the construction right-of-way since mitigation will avoid any impacts, but could indirectly affect portions of a population adjacent to the right-of-way in the Vegetation LSA through changes to dust, light or moisture levels.

- Duration: short-term – the events resulting in potential disturbance or alteration of a vegetation species at risk is clearing during construction of the pipeline or maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year during the operations phase.

- Frequency: periodic – the events resulting in potential disturbance or alteration of a vegetation species at risk will occur during construction and intermittently but repeatedly (*i.e.*, maintenance activities) during the operations phase of the Project.

- Reversibility: medium to long-term – depending on the species and the mitigation measures applied.

- Magnitude: medium – the potential disturbance or alteration of a vegetation species at risk would be of high magnitude since residual effects would exceed regulatory standards, but any vegetation species at risk populations will be avoided and indirect effects will be mitigated. Residual effects will not exceed regulatory standards.

- Probability: low – there was one vegetation species at risk potentially identified within the proposed pipeline corridor during the rare plant surveys in 2013. With mitigation from Table 7.2.9-3 and the Pipeline EPP of Volume 6B applied, it is unlikely that vegetation species at risk will interact with the Project Footprint.

- Confidence: high – based on past pipeline projects, the professional experience of the assessment team and the results of the rare plant surveys.

Combined Effects on Plant and Lichen Species of Concern

An evaluation of combined effects considers those residual environmental effects that are likely to occur. Most of the potential residual environmental effects related to plant and lichen of concern evaluated in Section 7.2.9.6 (points 2[a] through 2[c] of Table 7.2.9-4), are of high probability, and consequently, were considered in the evaluation of combined effects on the plant and lichen species of concern indicator. The potential residual environmental effect related to species at risk was determined to be of low probability and so was not included in the combined effects discussion.

The residual effects included:

- some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site;

- some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site; and

- if rare plant or lichen sub-populations are located adjacent to the construction right-of-way they may be affected by changes in hydrology, dust or light levels.

The adverse effects identified have the potential to act in combination on plant and lichen species of concern encountered along the proposed pipeline corridor. The reversibility of this residual effect is considered medium to long-term depending on the species, the land use and the mitigation measures. However, the magnitude of the combined effects on the plant and lichen species of concern indicator is considered to be medium since the combined effect is likely to be reduced by implementation of mitigation strategies for each of the residual effects (Table 7.2.9-4, point 2[e]). In addition, effects on plant and lichen species of concern will be monitored as part of the post-construction environmental monitoring program (Volume 6A). A summary of the rationale for all of the significance criteria of combined effects on plant and lichen species of concern is provided below.

- Spatial Boundary: Vegetation LSA – combined effects on the plant and lichen species of concern indicator may extend beyond the pipeline right-of-way.
- Duration: short-term – the events causing the combined effects on the plant and lichen species of concern indicator are pipeline construction of the pipeline and maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events causing the combined effects on the plant and lichen species of concern indicator (*i.e.*, pipeline construction and maintenance activities) is generally confined to the construction period but may occur intermittently but repeatedly during the operations phase.
- Reversibility: medium to long-term – depending on the species and the mitigation measures applied.
- Magnitude: medium - the potential disturbance or alteration of a rare plant and lichen population is of medium magnitude since the effect is still within environmental standards given that best practices, objectives and provincial guidelines are being followed.
- Probability: high – there are numerous rare plant and lichen species identified along the Project corridor and it is likely that they will interact with the Project Footprint.
- Confidence: high – based on available research literature, data from previous projects and the professional experience of the assessment team.

Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern

The following provides the evaluation of significance of potential residual effects on the weed and invasive species indicator.

Weed Introduction and Spread

Non-native and invasive species tend to be pioneer species with characteristics that can exploit recently disturbed ecosystems. Non-native and invasive species that occur at high densities on the landscape can exert competitive pressure on native vegetation and result in alteration of native vegetation. Weeds and non-native, invasive species were identified as a concern in both ESA and Community Workshops (*i.e.,* Hope, Merritt, Hinton, Edson, Burnaby, Coquitlam, Abbotsford, Clearwater, Kamloops and Langley).

In general, invasive species are most prevalent where the ground has been disturbed by anthropogenic activity. During the 2013 vegetation surveys, any weed species encountered were noted and their density/distribution was recorded (see the Vegetation Technical Report of Volume 5C). The information collected during the vegetation surveys allows for an understanding of baseline weed conditions and the magnitude of weed infestations encountered in areas supporting native vegetation along the proposed corridor.

Mitigation measures outlined in Table 7.2.9-3 and in the Pipeline EPP of Volume 6B are effective industry standard measures to reduce the potential for the introduction and spread of weeds. These measures will be implemented during both construction and maintenance of the Project. All problem vegetation along the construction right-of-way will be monitored during all pipeline construction phases (*i.e.,* pre-construction and construction) and the operations phase (*i.e.*, post-construction environmental monitoring) (Section 12.0 of Appendix C of the Pipeline EPP of Volume 6B).

Experience during past pipeline construction programs has shown that, while weed infestations were encountered, the implementation of appropriate mitigation measures during construction resulted in limited weed issues (Alliance 2002, IPL 1995, Enbridge 2000, 2002, TERA 2012a).

Specific learnings from the TMX Anchor Loop Project (TERA 2013a) regarding weed introduction and spread include:

- chemical and mechanical weed treatments were effective at controlling or suppressing non-native invasive broadleaf species of concern along and off the right-of-way, at temporary facilities and permanent facilities; and
- hand (manual) removal of vegetation in riparian areas (areas where chemical treatment was not allowed due to proximity to water) was effective in controlling or suppressing non-native broadleaf weeds.

In addition, the final post-construction environmental monitoring report for the TMX Anchor Loop Project indicated that after 5 years, the post-construction vegetation management program had effectively controlled or suppressed non-native invasive broadleaf species of concern, identified during the pre-construction survey, along the right-of-way (TERA 2013a).

The potential introduction or spread of Noxious weeds and invasive, non-native species may vary in the period required to reverse the effect depending on the land use affected and the species. Consequently, the residual effect is considered to be reversible in the short to medium-term and of low to medium magnitude (Table 7.2.9-4, point 3[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Vegetation RSA – potential weed introduction and spread resulting from pipeline construction and maintenance activities may extend beyond the Footprint and Vegetation LSA to the Vegetation RSA.
- Duration: short-term – the events resulting in potential weed introduction and spread are construction of the pipeline or site-specific maintenance activities (*e.g.,* integrity digs), the latter of which are limited to any 1 year during the operations phase.
- Frequency: periodic – the events resulting in potential weed introduction and spread (*i.e.*, pipeline construction, operations and maintenance activities) occur during construction and intermittently, but, repeatedly over the assessment period.
- Reversibility: short to medium-term – depending on the weed species, the size/location of the weed occurrence and the associated land use.
- Magnitude: low to medium – the proposed pipeline corridor parallels existing disturbances for 89% of the length and the east and west ends of the proposed pipeline corridor are on highly developed agricultural and urban areas with higher densities of weeds than native land uses. Based on consultation, weeds are a concern in populated areas. Magnitude varies from low to medium depending on the weed or invasive plant species, affected land use and density/distribution of associated weed occurrences.
- Probability: high – pipeline construction is expected to cause some weed introduction and spread.
- Confidence: high – based on past pipeline projects, the professional experience of the assessment team and post-construction environmental monitoring results.

7.2.9.7 Summary

As identified in Table 7.2.9-4, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on vegetation indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline construction and operations on vegetation will be not significant.

7.2.10 Wildlife and Wildlife Habitat

This subsection describes the potential interactions between the Project and wildlife and wildlife habitat. Project construction and operational activities have the potential to affect wildlife and wildlife habitat through changes in habitat, movement and mortality risk. The evaluation of potential Project effects on wildlife and wildlife habitat has been conducted considering all of the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations, power lines, and the Westridge Marine Terminal), because the components will have similar effect pathways (*i.e.,* changes in habitat, movement and mortality risk) on wildlife indicators, and disaggregation of effects by Project component is not meaningful at an individual or population level for wildlife indicators. The Wildlife Technical Report of Volume 5C and the Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C provide further information on existing conditions related to wildlife and wildlife habitat.

7.2.10.1 Assessment Indicators and Measurement Endpoints

Narrowing the issues assessed and selecting indicators that reflect project issues, and public and regulator interests is an accepted approach used to focus impact assessments on issues that are non-trivial (Hegmann *et al.* 1999, Hegmann *et al.* 2002, Finely and Revel 2002, Antoniuk 2000, Antoniuk 2002). It is common practice in conservation biology to use focal or indicator species to illustrate a response to environmental changes that may apply to other species with similar ecological requirements (Niemi and McDonald 2004, Noss 1990). Beanlands and Duinker (1983) suggest that ecological scoping by way of studying indicators to allow useful predictions to be made for other valued ecosystem components is a useful tool in environmental impact assessments, which considers practical constraints posed by time limitations, natural variability, the state of ecological knowledge and the scientific tools available.

For the assessment of wildlife and wildlife habitat, indicators were selected based on their potential to interact with, and be adversely affected by, the Project. The potential adverse effects of the Project considered are related to changes in habitat, movement and mortality risk, and include both direct and indirect pathways arising from the construction and operations of the Project. Feedback on indicator selection was solicited from regulatory authorities and local biologists. Indicator selection was informed and verified by TEK collected during participation in field studies for the Project. A summary of consultation and engagement related to wildlife and wildlife habitat is provided in Section 3.0 of this volume. All comments and suggestions were considered, and many were incorporated in the selection of wildlife indicators. Of particular influence was the direction provided by Environment Canada to balance the indicators in a manner that would ensure the broader wildlife community (*e.g.*, common and more abundant species indicators) is evaluated, in addition to a selection of species at risk and individual species of concern (consultation information is provided in Table 2.1 of the Wildlife Technical Report in Volume 5C). As a result, a combination of wildlife indicators was selected to include:

- wildlife communities by habitat type (*e.g.,* pond-dwelling amphibians);
- species groups (*e.g.,* bats, forest furbearers);
- species at risk (*e.g.,* woodland caribou); and
- species of management concern or of social or cultural importance (*e.g.,* moose).

The indicators for wildlife and wildlife habitat are listed in Table 7.2.10-1. The selection of indicators for the wildlife and wildlife habitat assessment allows for a focused evaluation of potential Project effects. However, field studies and mitigation planning were designed to be inclusive of species, communities and habitats that are not specifically addressed as an indicator.

One or more 'measurement endpoints' are identified for each wildlife indicator to allow quantitative or qualitative measurement of potential Project effects (Table 7.2.10-1). The degree of change in these measurable parameters is used to inform the characterization of the magnitude of potential Project-related effects on the wildlife indicators. A selection of the measurement endpoints may comprise the variables for study in monitoring and follow-up programs. In addition, the selection of indicators and measurement endpoints took into consideration the requirements of the NEB *Filing Manual* for the wildlife and wildlife habitat element in Table A-2.

TABLE 7.2.10-1

WILDLIFE INDICATORS AND MEASUREMENT ENDPOINTS

Wildlife Indicators	Measurement Endpoints	Rationale for Indicator Selection
Grizzly bear	• Baseline information: incidental field observations (tracks, scat, signs, visual), literature/published research • Change in area (ha) of suitable spring and fall foraging habitat within LSA (habitat models) • Change in movement (qualitative) • Change in mortality risk quantified by change in motorized access density within RSA	Potential for Project interaction; conservation status; management and cultural importance; environmental indicator (sensitive to disturbance).
Woodland caribou	• Baseline information: literature/published research • Change in area (ha) of direct and functional habitat disturbance within Caribou RSA • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; management and cultural importance; environmental indicator (sensitive to disturbance).
Moose	• Baseline information: winter track density and abundance by route segment and Natural Region or Ecoprovince (relative abundance); incidental field observations; literature/published research • Change in area (ha) of suitable winter forage and winter security/thermal habitat within LSA (habitat models) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; management and cultural importance.
Forest furbearers	• Baseline information: winter track density and abundance route segment and Natural Region or Ecoprovince for fisher/marten and wolverine (relative abundance); incidental field observations; literature/published research • Change in area (ha) of suitable marten living habitat (habitat model) • Change in availability of suitable fisher reproductive habitat (habitat model) • Change in wolverine habitat (qualitative) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; several furbearer species (*e.g.,* marten, fisher and wolverine) are of conservation, management and cultural importance; environmental indicator (sensitive to environmental change).
Coastal riparian small mammals	• Baseline information: literature/published research • Change in area (ha) of suitable mountain beaver living habitat (habitat model) • Change in area (ha) of habitat capability rated moderate to high for Pacific water shrew (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; group includes species with conservation status of concern; environmental indicator (sensitive to change); indicative of potential effects on species relying on coastal riparian habitat.
Bats	• Baseline information: incidental field observations of habitat features; literature/published research • Change in area (ha) of tree-roosting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; group includes several species with conservation status of concern; environmental indicator (sensitive to change).
Grassland/shrub-steppe birds	• Baseline information: breeding bird density, diversity and richness by route segment and Natural Region or Ecoprovince; incidental field observations; literature/published research • Change in area (ha) of grassland and shrub-steppe bird community habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the broader suite of bird species potentially affected in grassland/shrub-steppe habitats; represents an important habitat type affected by the Project (*i.e.*, native grasslands in the southern interior region of BC); various species (at risk and common) are addressed.
Mature/old forest birds	• Baseline information: breeding bird density, diversity and richness by route segment and Natural Region or Ecoprovince; incidental field observations; literature/published research • Change in area (ha) of mature/old forest bird community habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the broader suite of bird species potentially affected in mature/old forest habitats; represents an important habitat type affected by the Project; various species (at risk and common) are addressed.

TABLE 7.2.10-1 Cont'd

Wildlife Indicators	Measurement Endpoints	Rationale for Indicator Selection
Early seral forest birds	• Baseline information: breeding bird density, diversity and richness by route segment and Natural Region or Ecoprovince; incidental field observations; literature/published research • Change in area (ha) of early seral forest bird community habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the broader suite of bird species potentially affected in early seral forest habitats; represents an important habitat type affected by the Project; various species (at risk and common) are addressed.
Riparian and wetland birds	• Baseline information: breeding bird density, diversity and richness by route segment and Natural Region or Ecoprovince for riparian habitats; wetland productivity (indicated breeding pairs, density, diversity and richness) for wetlands surveyed; trumpeter swan brood count (in Alberta); incidental field observations; literature/published research; wetland function • Change in area (ha) of riparian and wetland bird community nesting habitat • Change in area (ha) of cavity nesting wetland bird community nesting habitat • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the broader suite of riparian and wetland bird species potentially affected; represents important habitat types affected by the Project; various species (at risk and common) are addressed.
Wood warblers	• Baseline information: breeding bird density by route segment and Natural Region or Ecoprovince (relative abundance); incidental field observations; literature/published research • Change in area (ha) of suitable nesting habitat for black-throated green warbler (habitat model) • Change in area (ha) of suitable nesting habitat for Cape May warbler (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the community of bird species (in particular warblers) potentially affected in mature spruce-dominant and mixedwood forests along the corridor in Alberta; conservation/management concern in Alberta; environmental indicators (sensitive to disturbance).
Short-eared owl	• Baseline information: presence/not detected by habitat type surveyed; incidental field observations; literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; indicative of potential effects on species relying on open habitats in grassland and forested regions over the length of the proposed corridor.
Rusty blackbird	• Baseline information: density by broad habitat type (relative abundance) if sufficient detections; incidental field observations; literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction (primarily in Alberta); conservation status; environmental indicator (sensitive to disturbance); indicative of potential effects on species relying on treed wetland and riparian habitats.
Flammulated owl	• Baseline information: incidental field observations; literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; environmental indicator (sensitive to disturbance); indicative of potential effects on species relying on Douglas-fir and ponderosa pine forest habitats in the southern interior region of BC.
Lewis's woodpecker	• Baseline information: literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; environmental indicator (sensitive to disturbance); indicative of potential effects on species relying on ponderosa pine and deciduous forest habitats in the southern interior region of BC.
Williamson's sapsucker	• Baseline information: literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; environmental indicator (sensitive to disturbance); indicative of potential effects on species relying on mixed deciduous Douglas-fir and ponderosa pine forest habitats in the southern interior region of BC.

TABLE 7.2.10-1 Cont'd

Wildlife Indicators	Measurement Endpoints	Rationale for Indicator Selection
Western screech-owl	• Baseline information: incidental field observations; literature/published research • Change in area (ha) of suitable nesting habitat for *kennicotti* and *macfarlanei* ssp. (habitat models) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; environmental indicator (sensitive to disturbance); indicative of potential effects on species relying on old/mature deciduous and mixedwood forest habitats in the interior and coastal regions of BC.
Great blue heron	• Baseline information: number counted from wetland and aerial surveys; incidental field observations; literature/published research • Change in habitat (qualitative) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; environmental indicator (sensitive to disturbance).
Spotted owl	• Baseline information: presence/not detected and number counted from spotted owl surveys; literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction (proposed corridor intersects Wildlife Habitat Area); conservation status; high regulator/public profile and concern; environmental indicator (sensitive to disturbance).
Bald eagle	• Baseline information: incidental field observations (visual, stick nests); literature/published research • Change in habitat (qualitative) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; cultural importance.
Common nighthawk	• Baseline information: presence/not detected by locations sampled; literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; species of interest for regulatory authorities.
Northern goshawk	• Baseline information: incidental field observations; literature/published research • Change in area (ha) of suitable nesting habitat for *laingi* ssp. (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation concern; environmental indicator (sensitive to disturbance); indicative of potential effects on species relying on mature/old forest.
Olive-sided flycatcher	• Baseline information: density by broad habitat type (relative abundance) if sufficient detections; incidental field observations; literature/published research • Change in area (ha) of suitable nesting habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; conservation status; indicative of potential effects on species relying on open forests with complex overstory characteristics, and species that use forest edges, openings and disturbed habitats.
Pond-dwelling amphibians	• Baseline information: presence/not detected and number counted in targeted wetland surveys; incidental field observations; literature/published research • Change in area (ha) of pond-dwelling amphibian breeding habitat (habitat model) • Change in area (ha) of suitable living habitat for western toad (habitat model) • Change in area (ha) of suitable living habitat for Great Basin spadefoot (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the broader suite of pond-dwelling amphibian species potentially affected by the Project; represents an important habitat type affected by project; various species (at risk and common) are addressed; environmental indicator (sensitive to disturbance).
Stream-dwelling amphibians	• Baseline information: presence/not detected and number counted in targeted stream surveys; incidental field observations; literature/published research • Change in area (ha) of suitable living habitat for coastal tailed frog (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the broader suite of stream-dwelling amphibian species potentially affected by the Project; represents an important habitat type affected by Project; various species (at risk and common) are addressed; environmental indicator (sensitive to disturbance).

TABLE 7.2.10-1 Cont'd

Wildlife Indicators	Measurement Endpoints	Rationale for Indicator Selection
Arid habitat snakes	• Baseline information: presence/not detected and number counted in targeted surveys for western rattlesnake hibernacula; incidental observations; literature/published research • Change in area (ha) of suitable rattlesnake living habitat (habitat model) • Change in movement (qualitative) • Change in mortality risk (qualitative)	Potential for Project interaction; addresses the broader suite of snake species potentially affected by the Project; conservation status; environmental indicator (sensitive to disturbance).

7.2.10.2 Spatial Boundaries

The spatial boundaries considered for the assessment of wildlife and wildlife habitat include:

- a Footprint Study area;
- a Wildlife LSA, defined generally as the area within a 1 km buffer of the centre of the proposed pipeline corridor and power lines, and within a 1 km buffer around the boundary of the proposed pump station and terminal facilities;
- a Wildlife RSA, defined generally as the area within a 15 km buffer of the centre of the proposed pipeline corridor and power lines, and within a 15 km buffer around the boundary of the proposed pump station and terminal facilities;
- a Grizzly Bear RSA, defined by the Grizzly Bear Population Units (GBPUs) traversed by the proposed pipeline corridor; and
- a Caribou RSA, defined by the Wells Gray and Groundhog caribou ranges and associated mountain caribou Ungulate Winter Range (UWR) and Wildlife Habitat Area (WHA).

The Project Footprint as defined in Section 7.1.3 is used in the characterization and determination of significance for potential Project effects on wildlife and wildlife habitat indicators. Because the Project is in early planning stages, assumptions were made to spatially delineate the Footprint used in the quantitative analysis of Project effects. The spatial Footprint was defined as a 45 m wide pipeline corridor (which would encompass the permanent right-of-way and likely temporary workspace), 50 m wide power line corridors, and the footprint of the proposed permanent facilities (based on available spatial information).

The Wildlife LSA encompasses the Project Footprint and extends beyond it to include the surrounding area where there is a reasonable potential for Project-specific effects to occur. The Wildlife LSA considers the wildlife species expected to interact with the Project, the effects pathways, and available information on wildlife sensitivity to disturbance (*e.g.*, zones of influence, setback distances). The Wildlife RSA encompasses the Project Footprint, Wildlife LSA and the broader surrounding area where there is potential for interaction with existing activities and reasonably foreseeable developments to have cumulative effects. Species-specific RSAs were delineated for grizzly bear and caribou to capture the biologically relevant spatial scale at which management for those species occurs. Spatial boundaries, including the Wildlife LSA, Wildlife RSA, Grizzly Bear RSA and Caribou RSA, are shown in Section 5.0 of this volume.

The spatial extents of the study areas represent a compromise between choosing a large area that would mask or dilute the effects of the Project, versus choosing a smaller area where the effects on the wildlife indicator under consideration may no longer be meaningful. There were no concerns with the spatial boundaries identified in consultation with provincial and federal regulatory authorities, local biologists, participants of ESA Workshops, and Aboriginal community representatives who participated in field studies for the Project.

Given the length of the proposed pipeline corridor and the variability in ecological systems encountered, many of the wildlife indicators occur only along discreet segments of the study areas. These segments and relevant project components are identified in Table 7.2.10-2. The Natural Subregions (Alberta) and Ecosections (BC) are illustrated in the Wildlife Technical Report of Volume 5C.

TABLE 7.2.10-2

PROJECT COMPONENTS AND ECOSYSTEM UNITS RELATIVE TO INDICATOR SPECIES DISTRIBUTION IN THE WILDLIFE LSA

Wildlife Indicator	Project Components	Ecosystem Units[1]
Grizzly bear	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Temporary facilities	Alberta: LF; M BC: NPK; UFT; CAM; NSH; CAP; NIB; HOR; EPR
Woodland caribou	Hargreaves to Darfield Temporary facilities	BC: CAM; NSH
Moose	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Temporary facilities Black Pines Pump Station and power line Kingsvale Pump Station and power line	Alberta: All Natural Subregions BC: NPK; UFT; CAM; NSH; CAP; North Thompson Upland; THB; GUU; NIB; HOR
Forest Furbearers	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Temporary facilities Black Pines Pump Station and power line Kingsvale Pump Station and power line	Alberta: DM; CM; LF; UF; M BC: All Ecosections
Coastal riparian small mammals	Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary facilities Sumas Terminal Westridge Marine Terminal	BC: HOR; EPR; NWC; FRL
Bats	All components	All Natural Subregions and Ecosections
Grassland/shrub-steppe birds	Hargreaves to Darfield Black Pines to Hope Temporary facilities Black Pines Pump Station and power line	BC: North Thompson Upland; THB; GUU; NIB; HOR
Mature/old forest birds	All components	All Natural Subregions and Ecosections
Early seral forest birds	All components	All Natural Subregions and Ecosections
Riparian and wetland birds	All components	All Natural Subregions and Ecosections

Common nighthawk	All components	All Natural Subregions and Ecosections
Northern goshawk *laingi* ssp.	Hope to Burnaby Burnaby to Westridge Temporary facilities Sumas Terminal Westridge Marine Terminal	BC: HOR; EPR; NWC; FRL
Olive-sided flycatcher	All components	All Natural Subregions and Ecosections
Pond-dwelling amphibians	All components	All Natural Subregions and Ecosections
Stream-dwelling amphibians	Black Pines to Hope Hope to Burnaby Temporary facilities Sumas Terminal	BC: HOR; EPR; NWC; FRL
Arid habitat snakes	Black Pines to Hope Temporary facilities	BC: THB

Note: 1 Ecosystem Units are defined by Natural Subregions in Alberta and Ecosections in BC. The Natural Subregions in Alberta include the Central Parkland (CP), Dry Mixedwood (DM), Central Mixedwood (CM), Lower Foothills (LF), Upper Foothills (UF) and Montane (M). The Ecosections in BC include Northern Park Ranges (NPK), Upper Fraser Trench (UFT), Cariboo Mountains (CAM), Northern Shuswap Highlands (NSH), Cariboo Plateau (CAP), North Thompson Upland, Thompson Basin (THB), Guichon Upland (GUU), Nicola Basin (NIB), Hozameen Range (HOR), Eastern Pacific Ranges (EPR), Northwestern Cascade Range (NWC) and Fraser Lowland (FRL).

7.2.10.3 Wildlife Assessment Approach Considerations

Comments received in consultation regarding the assessment approach, including spatial boundaries, indicator selection, field studies and proposed measurement endpoints, were considered in the development of the wildlife and wildlife habitat effects assessment. A summary of consultation related to wildlife and wildlife habitat is provided in Section 3.0. All comments and suggestions were considered, and many were incorporated in the development of the assessment approach for wildlife and wildlife habitat. In some cases, recommendations were considered, but scoped out of the assessment for various reasons. For example, several wildlife species were suggested for inclusion as indicators in the effects assessment but ultimately were not included. Scoping was necessary to narrow the suite of indicators assessed in order to focus the assessment and provide information in a concise manner. Species that were scoped out of the assessment may have had limited interaction with the terrestrial components of the Project or mitigation is expected to eliminate or reduce potential Project effects to negligible levels (*e.g.*, river otter, American badger), or the expected effects are similar to those addressed by another indicator.

In addition, recommendations regarding field survey protocols were generally adopted; however, modifications were required for some field surveys to ensure the surveys were appropriate for the scope of the Project, and in consideration of logistical limitations. Where warranted, pre-construction surveys may be completed to collect information needed to inform mitigation planning.

7.2.10.4 Ecological and Regulatory Context

The following subsections summarize the general ecological and regulatory context relevant to wildlife and wildlife habitat for each of the Project segments. Additional context is provided for the indicators used to assess wildlife and wildlife habitat in Sections 7.2.10.9 (mammals), 7.2.10.10 (birds), 7.2.10.11 (amphibians) and 7.2.10.12 (reptiles).

<u>Edmonton to Hinton Segment</u>

Wildlife indicators relevant to the Edmonton to Hinton Segment include grizzly bear, moose, forest furbearers, bats, mature/old forest birds, early seral forest birds, riparian and wetlands birds, wood warblers, short-eared owl, rusty blackbird, great blue heron, bald eagle, common nighthawk, olive-sided flycatcher and pond-dwelling amphibians (Table 7.2.10-2).

The Edmonton to Hinton Segment traverses a mosaic of land uses and habitat types, including suburban and rural areas, agricultural fields (*i.e.*, cultivation and hay fields), pasture and forest. Within areas dominated by agricultural land use, wildlife activity is typically concentrated in patches of residual forest, wetlands and grasslands (including tame pasture). Forested areas include deciduous, coniferous and mixedwood forests comprised of trembling aspen, white spruce, black spruce, jack pine, balsam fir and, less commonly, balsalm poplar and paper birch. Upland mixedwood forests have been subject to forest harvesting activities and are at various stages of regeneration. Two sections of the Edmonton to Hinton Segment cross wildfire burns that occurred within the last 40 years: RK 188.7 to RK 189.4 (burned in 2009); and RK 135.9 to RK 136.3 (burned in 2012) (AESRD 2013c). Terrain is generally level to gently undulating along the Edmonton to Hinton Segment, with moderate to steep slopes encountered at watercourse crossings (*i.e.*, the North Saskatchewan, Pembina, McLeod and Athabasca rivers) and gently to moderately undulating terrain within the Lower Foothills and Montane Natural Subregions. Most of the wetlands encountered along the proposed pipeline corridor within the Edmonton to Hinton Segment are surrounded by cultivation or tame pasture, with larger expanses of treed bogs and fens encountered towards the western portion of the segment. Detailed information on wetlands and wetland function is available in the Wetland Evaluation Technical Report of Volume 5C. The Edmonton to Hinton Segment parallels existing linear disturbances for approximately 233 km (68.7%) of its length. Habitat alteration as a result of urbanization, agriculture and resource extraction (*e.g.*, forestry, oil and gas activity) has altered the suitability and use of wildlife habitat within the Wildlife RSA. Clearing of vegetation, the creation of linear corridors, facilities and/or infrastructure, and sensory disturbance associated with development and resource use have affected the historical distribution and movement of wildlife.

The Edmonton to Hinton Segment intersects Key Wildlife and Biodiversity Zones associated with the North Saskatchewan and Athabasca rivers, Special Access Zones, Grizzly Bear Core and Secondary Areas, Sensitive Raptor Range for bald eagle, Sharp-tailed Grouse Range, and is located within 800 m of several trumpeter swan waterbodies (Table 4.1.3 in Wildlife Technical Report of Volume 5C). The proposed pipeline corridor is north of Wabamun Lake Provincial Park, and is separated from the park by Highway 16. Wabamun Lake provides year-round habitat for a variety of migrating, breeding and molting water birds (ATPR 2012a,b). at its nearest point (approximately RK 96.0), the Edmonton to Hinton Segment is approximately 200 m north of Wabuman Lake (Wildlife Technical Report of Volume 5C, Table 4.1.5). Protective Notations (PNTs) for fragmented land pattern, ungulate winter range, fish and wildlife resource management area, research site structure, habitat management area for a Foothills Model Forest study, and a habitat protection area for long-toed salamander are located within the proposed pipeline corridor (Wildlife Technical Report of Volume 5C).

Provincial management objectives and guidelines related to wildlife in the Wildlife LSA are set out by the Government of Alberta in the *Integrated Standards and Guidelines* for the Enhanced Approval Process (Government of Alberta 2013a). This document includes recommendations for setback distances and timing restrictions for sensitive species, and guidelines for working in sensitive areas. Where applicable, the recommendations in the *Integrated Standards and Guidelines* are incorporated in mitigation planning for the Project. In addition to the provincial objectives, the Edmonton to Hinton Segment crosses the following planning areas:

- Capital Region Land Use Plan (Capital Region Board 2009);
- Coal Branch Sub-Regional Integrated Resource Plan (Government of Alberta 1990);
- Edmonton Environmental Strategic Plan (City of Edmonton 2011);
- Edmonton Municipal Development Plan (City of Edmonton 2010);
- Edson Municipal Development Plan (Town of Edson 2006);
- Edson Urban Fringe Intermunicipal Development Plan (Yellowhead County 2007);
- Entwistle Area Structure Plan (Parkland County 2012);
- Hinton Municipal Development Plan (Town of Hinton 1998);
- Hinton Community Sustainability Plan (Citizens Advisory Group 2011);
- Lake Wabamun Management Plan (Yellowhead Regional Planning Commission 1985);
- Northern East Slopes Sustainability Resource and Environmental Management Strategy (Government of Alberta 2003);
- Parkland County Municipal Development Plan and Integrated Community Sustainability Plan (Parkland County 2007, 2011);
- Spruce Grove Municipal Development Plan (City of Spruce Grove 2010);
- Stony Plain Community Sustainability Plan (Town of Stony Plain 2007);
- Stony Plain Municipal Development Plan (Town of Stony Plain 2005);
- Strathcona County Municipal Development Plan (Strathcona County 2007);
- Wabamun Municipal Development Plan (Village of Wabamun 2010); and
- Yellowhead County Municipal Development Plan (Yellowhead County 2006).

These plans have identified objectives, goals and/or strategies related to wildlife, habitat, biodiversity and ecosystem integrity, which are summarized in Appendix E of the Wildlife Technical Report of Volume 5C. In general, these plans in relation to wildlife and wildlife habitat stress the importance of protecting rare and sensitive flora, fauna and habitat, reducing the impacts of development on the natural environment, enhancing biodiversity and restoring disturbed and ecologically degraded and/or damaged areas. There is a particular focus on ungulates (*e.g.*, elk, moose, deer, mountain goat, and bighorn sheep), furbearers, upland games birds, species of concern (*e.g.*, peregrine falcon, trumpeter swan and long-toed salamander) and non-game species of wildlife in the some of the resource plans.

Hargreaves to Darfield Segment

Wildlife indicators relevant to the Hargreaves to Darfield Segment include grizzly bear, woodland caribou, moose, forest furbearers, bats, grassland/shrub-steppe birds, mature/old forest birds, early seral forest birds, riparian and wetland birds, short-eared owl, rusty blackbird, great blue heron, bald eagle, common nighthawk, olive-sided flycatcher and pond-dwelling amphibians (Table 7.2.10-2).

The Hargreaves to Darfield Segment crosses a mosaic of land uses and habitat types, including suburban areas associated with cities and towns, agricultural fields, pasture and forested areas. Forested areas are generally comprised of Douglas-fir, Engelmann spruce, white spruce, lodgepole pine, and trembling aspen, with ponderosa pine encountered on warm, dry slopes towards the southern end of the Hargreaves to Darfield Segment. A number of cutblocks in various stages of regeneration are encountered along the proposed pipeline segment. There is also evidence of selective harvesting in many areas. Two sections of the Hargreaves to Darfield Segment cross wildfire burns that occurred within the last 40 years: RK 639.6 to RK 647.3 (burned in 1998); and RK 706.4 to RK 706.5 (burned in 2007) (BC MFLNRO 2013b). Much of the forested land along this segment is range tenure used for cattle grazing. Agricultural lands (*i.e.*, cultivated fields, hay and tame pasture), rural and suburban residential areas are traversed in the valley bottoms and in the vicinity of communities, including Avola, Clearwater and Little Fort. Terrain encountered along the proposed corridor varies from flat to gently undulating on wide valley bottoms, to moderately undulating hills and steeper slopes along some watercourses and narrow valleys. Wetlands within the corridor are generally associated with streams and oxbow lakes, with a number of marshes, fens and swamps. Detailed information on wetlands and wetland function is available in the Wetland Evaluation Technical Report of Volume 5C. The Hargreaves to Darfield Segment parallels existing linear disturbances (*i.e.*, the existing Trans Mountain pipeline right-of-way and Highway 5) for approximately 205.3 km (73.5%) of its length. Habitat alteration as a result of urbanization, agriculture, transportation and resource extraction (*e.g.*, forestry) has altered the suitability and use of wildlife habitat within the Wildlife RSA. Clearing of vegetation, the creation of linear corridors, facilities and/or infrastructure, and sensory disturbance associated with development and resource use have affected the historical distribution and movement of wildlife.

The Hargreaves to Darfield Segment intersects the Wells Gray and Groundhog caribou ranges and ungulate winter range (UWR) for mountain caribou (within the Wells Gray caribou range) (Wildlife Technical Report of Volume 5C). The BC *Oil and Gas Activities Act* (*BC OGAA*) states that operating areas should not be located in a designated UWR unless the operating area will not have a material adverse effect on the ability of the wildlife habitat within the UWR to provide for the survival, within the UWR, of the wildlife species for which the UWR was established. Within the intersected UWR, the proposed corridor parallels the existing TMPL right-of-way, Highway 5, and an existing railway. It is likely that caribou currently avoid habitat along the proposed pipeline corridor, given that woodland caribou have demonstrated avoidance of such disturbance features (Dyer *et. al.* 2001).

The proposed pipeline corridor is located within the Finn Creek and North Thompson River provincial parks, and is adjacent to Jackman Flats and Blue River Black Spruce provincial parks (Wildlife Technical Report of Volume 5C). Refer to Section 7.2.4.6 of Volume 5B for additional information regarding requirements associated with development within the parks.

The Hargreaves to Darfield Segment crosses the following planning areas:

- Blue River Official Community Plan (Thompson-Nicola Regional District 2011a);
- Avola Official Community Plan (Thompson-Nicola Regional District 2011d);
- District of Clearwater Official Community Plan (District of Clearwater 2012);
- Eight Peaks Winter Recreation Sustainable Resource Management Plan (BC Ministry of Sustainable Resource Management [MSRM] 2003);
- Kamloops Land and Resource Management Plan (BC Integrated Land Management Bureau [ILMB] 1995);
- Regional District of Fraser-Fort George Official Community Plan (Regional District of Fraser-Fort George 2013);
- Robson Valley Land and Resource Management Plan (BC ILMB 1999);
- Thompson-Nicola Regional Growth Strategy (Thompson-Nicola Regional District 2000);
- Valemount to Blue River Winter Recreation Sustainable Resource Management Plan (BC ILMB 2005); and

- Village of Valemount Official Community Plan (Village of Valemount 2006).

These plans have identified objectives, goals and/or strategies related to wildlife, habitat, biodiversity and ecosystem integrity, which are summarized in the Wildlife Technical Report of Volume 5C (Appendix E). In general, these plans in relation to wildlife and wildlife habitat stress the importance of promoting conservation and sustainability of watershed ecosystems, wetlands and riparian areas and protecting environmentally sensitive and unique natural areas. Some LRMPs/SRMPs are particularly focused on grizzly bears, ungulates (*e.g.*, caribou, mountain goat, moose, elk and deer) and waterfowl. Grizzly bear objectives include minimizing impacts on grizzly bear habitats and human/bear conflicts, and maintaining or enhancing habitat, population size, genetic variability and distribution. Objectives specific to caribou include avoiding displacement and disturbance of mountain caribou, particularly in core early and late winter habitat, and improving understanding of the behaviour and biology of caribou populations.

Black Pines to Hope Segment

Wildlife indicators relevant to the Black Pines to Hope Segment include grizzly bear, moose, forest furbearers, coastal riparian small mammals, bats, grassland/shrub-steppe birds, mature/old forest birds, early seral forest birds, riparian and wetland birds, short-eared owl, rusty blackbird, flammulated owl, Lewis's woodpecker, Williamson's sapsucker, western screech-owl, great blue heron, spotted owl, bald eagle, common nighthawk, olive-sided flycatcher, pond-dwelling amphibians, stream-dwelling amphibians, and arid habitat snakes (Table 7.2.10-2).

The Black Pines to Hope Segment traverses a mosaic of land uses and habitat types, including suburban areas and rural areas, agricultural fields (*i.e.*, cultivation, hay), pasture, grasslands and forests. Forested areas are generally dominated by Douglas-fir and ponderosa pine, with open, grassy understories, particularly in ponderosa pine stands. Areas of ponderosa pine forest also contain large open grassland areas interspersed with big sage brush. Selective forest harvest is common along this segment, as evidenced by old stumps on the forest floor and sporadic large veteran Douglas-fir trees. The grasslands north and south of Kamloops show signs of human disturbance in the form of trails, access roads and cattle grazing. The Black Pines to Hope Segment traverses several areas burned by wildfire within the last 40 years: RK 830.1 to RK 830.7 (burned in 1987); RK 826.5 to RK 826.6 (burned in 2008); and RK 826.3 to RK 826.7 (burned in 2009) (BC MFLNRO 2013b). Terrain along the proposed pipeline segment varies from flat to gently undulating in large valley bottoms, to moderately and steeply undulating hills through the grasslands and forested areas north and south of Kamloops. Steeper slopes are encountered along some watercourses and narrow valleys (*e.g.*, Coquihalla valley). Wetlands encountered by the Black Pines to Hope Segment and are generally associated with streams and oxbow lakes, with a number of shrubby/treed fens and bogs. Pipeline routing avoids wetlands to the extent feasible. The Ajax-Afton open pit mine is located from RK 853.5 to RK 858.5. The Black Pines to Hope Segment parallels existing linear disturbances (*i.e.*, the existing TMPL right-of-way and Highway 5) for approximately 129.3 km (55.8%) of its length. Habitat alteration as a result of urbanization, agriculture and resource extraction (*e.g.*, forestry, mining) has altered the suitability and use of wildlife habitat within the Wildlife RSA. Clearing of vegetation, the creation of linear corridors, facilities and/or infrastructure, and sensory disturbance associated with development and resource use have affected the historical distribution and movement of wildlife.

The Black Pines to Hope Segment intersects UWRs for mule deer and black-tailed deer, and a Wildlife Habitat Area (WHA) for spotted owl. The Kingsvale Pump Station is located adjacent to UWR for mule deer and the proposed pump station power line intersects a WHA for Williamson's sapsucker (Wildlife Technical Report of Volume 5C). The *BC OGAA* adopts the same policy for WHAs as UWRs (refer to Hargreaves to Darfield Segment above). The proposed pipeline corridor intersects the Sowaqua Spotted Owl WHA, which is classified as a Long-Term Owl Habitat Area (LTOHA).

The proposed pipeline corridor is located within Lac du Bois Grasslands Protected Area and the Coquihalla Summit Recreation Area, and is adjacent to the Coldwater River, Coquihalla River and Coquihalla Canyon provincial parks. It is also located within the Douglas Lake Plateau IBA (BC172) (Bird Studies Canada and Nature Canada 2013) and the DUC Level 3 Priority Landscape, Eastern Boreal Forest, which encompasses areas rich in wetlands, lakes, ponds, rivers, and streams and supports breeding, migrating, moulting, and staging waterfowl (DUC 2013).

The Blackpines to Hope Segment crosses the following planning areas:

- Hope Official Community Plan (District of Hope 2004);
- Kamloops KAMPLAN (City of Kamloops 2004);
- Kamloops Land and Resource Management Plan (BC ILMB 1995);
- Kamloops North Official Community Plan (Thompson-Nicola Regional District 2011b);
- Kamloops South Official Community Plan (Thompson-Nicola Regional District 2011c);
- Merritt Official Community Plan (City of Merritt 2011); and
- Thompson-Nicola Regional Growth Strategy (Thompson-Nicola Regional District 2000).

These plans have identified objectives, goals and/or strategies related to wildlife, habitat, biodiversity and ecosystem integrity, which are summarized in the Wildlife Technical Report of Volume 5C (Appendix E). In general, these plans in relation to wildlife and wildlife habitat stress the importance of promoting conservation and sustainability of watershed ecosystems, wetlands and riparian areas, and protecting environmentally sensitive and unique natural areas. The Kamloops LRMP in particular focuses on riparian management, ecosystem management, biodiversity, and maintaining or enhancing ungulate (*i.e.*, moose, deer) habitat requirements (*e.g.*, forage production, thermal and visual cover).

Hope to Burnaby Segment

Wildlife indicators relevant to the Hope to Burnaby Segment include forest furbearers, coastal riparian small mammals, bats, mature/old forest birds, early seral forest birds, riparian and wetland birds, short-eared owl, rusty blackbird, western screech-owl, great blue heron, bald eagle, common nighthawk, northern goshawk, olive-sided flycatcher, pond-dwelling amphibians, and stream-dwelling amphibians (Table 7.2.10-2).

Portions of the proposed Hope to Burnaby Segment, particularly west of RK 1048, have a high level of anthropogenic disturbance which is characterized by agricultural fields (cultivation, hay, tame pasture), and urban, residential and industrial complexes located within and in the vicinity of Chilliwack, Abbotsford, Langley and Burnaby. These areas are identified for the purposes of the assessment as the Lower Mainland Developed Area (LMDA). Within the LMDA, residual forest is dominated by western redcedar, western hemlock and Douglas-fir. East of the LMDA to Hope, forested areas are typically dominated by Douglas-fir, western hemlock and western redcedar, with open understories. Riparian areas are dominated by black cottonwood. Wetlands encountered along this segment are generally associated with streams and oxbow lakes, with a number of shrubby/treed fens and bogs. The Hope to Burnaby Segment follows south of the Fraser River and the terrain is generally flat with some undulating hills. The proposed Hope to Burnaby Segment parallels existing linear disturbances for approximately 93.4 km (68.6%) of its length. Habitat alteration as a result of urbanization, agriculture, resource extraction (*e.g.*, forestry) and industrial development has altered the suitability and use of wildlife habitat within the Wildlife RSA. Clearing of vegetation, the creation of linear corridors, facilities and/or infrastructure, and sensory disturbance associated with development and resource use have affected the historical distribution and movement of wildlife.

Throughout the Wildlife LSA and RSA along the Hope to Burnaby Segment, there are residual pockets of habitat for suitable various wildlife species. These residual habitat patches are of increasing importance, given the existing level of cumulative disturbance. The Hope to Burnaby Segment crosses the Cheam Lake Wetlands Regional Park from RK 1079.9 to RK 1080.0, and is adjacent to the southeast boundary of the park from RK 1080.1 to RK 1080.4 where the proposed corridor is located on private land and is separated from the park by a secondary road. Trans Mountain is currently investigating route alternatives to avoid the Cheam Lake Wetlands Regional Park (Section 4.0); however, for the purposes of this assessment, it is assumed the route will cross the park. The Cheam Lake Wetlands Regional Park protects 93 ha of marsh, lake and uplands, and is one of the most mineral-rich wetlands in the Fraser Valley (Fraser Valley Regional District 2008).

The Hope to Burnaby Segment will parallel the existing TMPL right-of-way through the segment of land that is leased by the Mountain View Conservation and Breeding Centre. The Mountain View Conservation and Breeding Centre is a non-profit organization that operates breed and return conservation programs in natural settings and enclosures for several rare and endangered species from BC and around the world (Mountain View Conservation and Breeding Centre 2013).

The Hope to Burnaby Segment transects the Sumas Mountain Interregional Park from RK 1115.2 to RK 1120.7. The area has been identified as having high biodiversity and supports species and ecosystems designated as at risk by the provincial and/or federal government (City of Abbotsford 2012). A portion of the proposed pipeline corridor in the Hope to Burnaby Segment is located along the southwest boundary of the Surrey Bend Regional Park from RK 1160.9 to RK 1164.3. The Surrey Bend Regional Park provides a mosaic of foreshore and upland habitats that support a variety of wildlife species and provides a habitat reservoir for many species.

The Hope to Burnaby Segment crosses the following planning areas:

- Abbotsford Community Sustainability Plan (City of Abbotsford 2013);
- Abbotsford Official Community Plan (City of Abbotsford 2005);
- Burnaby Environmentally Sensitive Areas Strategy (City of Burnaby 1994);
- Burnaby Official Community Plan (City of Burnaby 1998);
- Burnaby State of the Environment Report (City of Burnaby 1993);
- Chilliwack Official Community Plan (City of Chilliwack 1998);
- Coquitlam Official Community Plan (City of Coquitlam 2001a);
- Fraser River Estuary Management Plan (Fraser River Estuary Management Program 2003);
- Greater Vancouver Regional Growth Strategy (Metro Vancouver 2011b);
- Greater Vancouver Strategic Directions for Biodiversity Conservation (Biodiversity Conservation Strategy Partnership 2008);
- Hope Official Community Plan (District of Hope 2004);
- Sumas Mountain Environmental Management Study (City of Abbotsford 2012);
- Surrey Bend Regional Park Management Plan (Metro Vancouver and City of Surrey 2010);
- Surrey Ecosystem Management Study (City of Surrey 2011); and
- Surrey Official Community Plan (City of Surrey 1996).

These plans have identified objectives, goals and/or strategies related to wildlife, habitat, biodiversity and ecosystem integrity, which are summarized in Appendix E of the Wildlife Technical Report of Volume 5C. In general, these plans in relation to wildlife and wildlife habitat stress the importance of enhancing habitat and park lands, protecting core habitat areas, large natural areas, watercourses, wetlands, riparian areas, corridors, topographic areas, reservoirs and refuges, promoting biodiversity, and minimizing impacts on rare or unique vegetation, wildlife and wildlife habitat.

Burnaby to Westridge Segment

Wildlife indicators relevant to the Burnaby to Westridge Segment include coastal riparian small mammals, bats, mature/old forest birds, early seral forest birds, riparian and wetland birds, short-eared owl, rusty blackbird, western screech-owl, great blue heron, bald eagle, common nighthawk, northern goshawk, olive-sided flycatcher, and pond-dwelling amphibians (Table 7.2.10-2).

The Burnaby to Westridge Segment is located within the LMDA, and characterized by residential neighbourhoods and industrial complexes within the City of Burnaby. Residual forest is dominated by western red cedar, western hemlock and Douglas-fir. Habitat alteration as a result of urbanization, commercial and industrial development has altered the suitability and use of wildlife habitat within the Wildlife RSA. Clearing of vegetation, the creation of linear corridors, facilities and/or infrastructure, and sensory disturbance associated with development and resource use have affected the historical distribution and movement of wildlife.

The Burnaby to Westridge Segment is located within the English Bay and Burrard Inlet IBA (BC020) from RK 3.2 to RK 3.6, which includes the shores of Burrard Inlet and English Bay. The IBA was designated primarily to protect western grebe, Barrow's goldeneye, surf scoter and great blue heron (*fannini* subspecies). The area also provides nesting habitat for pelagic and double-crested cormorants, osprey and bald eagle, and purple martins are commonly found nesting in nest-boxes along the shores (Bird Studies Canada and Nature Canada 2013). The proposed pipeline corridor is also located within the DUC Priority 2 Landscape, BC Coastal Areas and Estuaries, which provides important migration and winter habitat that supports a wintering population of over one million waterfowl (DUC 2013). The Burnaby to Westridge Segment traverses the southwest boundary of the Burnaby Mountain Conservation Area from RK 0.6 to RK 2.0. The proposed pipeline corridor parallels the Burnaby Mountain Parkway along this stretch and is located within a forested area. The Burnaby Mountain Conservation Area is a forested mountain ecosystem that provides habitat for a variety of species, including blacktail deer, coyote, bald eagle, black bear and cougar (City of Burnaby 2013).

The Burnaby to Westridge Segment crosses the following planning areas:

- Burnaby Environmentally Sensitive Areas Strategy (City of Burnaby 1994);
- Burnaby Official Community Plan (City of Burnaby 1998);
- Burnaby State of the Environment Report (City of Burnaby 1993);
- Burrard Inlet Environmental Action Program and *Shoreline Development Guidelines* (Burrard Inlet Environmental Action Program 2002, 2005);
- Fraser River Estuary Management Program (Fraser River Estuary Management Program 2003);
- Greater Vancouver Regional Growth Strategy (Metro Vancouver 2011b); and
- Greater Vancouver Strategic Directions for Biodiversity Conservation (Biodiversity Conservation Strategy Partnership 2008).

These plans have identified objectives, goals and/or strategies related to wildlife, habitat, biodiversity and ecosystem integrity, which are summarized in Appendix E of the Wildlife Technical Report of Volume 5C. In general, these plans in relation to wildlife and wildlife habitat stress the importance of enhancing habitat and park lands, protecting core habitat areas, large natural areas, reservoirs and refuges, connecting habitat areas and enhancing and restoring biodiversity. Some of the plans focus primarily on marine environments (*e.g.*, shorelines, estuaries and inlets) and migratory birds.

7.2.10.5 Identified Potential Effects

The potential environmental effects associated with the construction and operations of the Project on wildlife and wildlife habitat were based on the results of a literature review, desktop analysis, field work, compiled ATK and information gathered during Aboriginal participation in field surveys, habitat modelling, as well as engagement with regulatory authorities, landowners and stakeholders (Section 3.0), and the professional experience of the assessment team.

Project construction and operations activities have the potential to directly and indirectly affect wildlife and wildlife habitat through alteration of vegetation, terrain and drainage, causing changes in wildlife habitat, movement and mortality risk. These effects mechanisms or "pathways" define the potential effects identified for the Project:

- change in habitat;
- change in movement; and
- increased mortality risk.

These three effects pathways reflect the concerns identified by Aboriginal communities through participation in wildlife field studies and through compilation of ATK. In general, Aboriginal communities have identified concerns about the impact of development, and cumulative effects of developments, on wildlife resources. Specific issues raised during Aboriginal participation in field studies included avoiding disturbance of important site-specific wildlife habitats such as nests, dens, mineral licks, ungulate foraging and calving areas, wetlands and watercourses. In addition, maintaining wildlife movement and access to important habitats (*i.e.,* connectivity) was identified by participants during the field studies (*e.g.,* keeping game trails open). Aboriginal communities raised concerns about sensory disturbance of wildlife during construction, and changes in habitat quality related to contamination (*e.g.*, spills, leaks, construction waste). Changes in access and the associated effects on predator-prey dynamics and human hunting is also a concern for Aboriginal communities. All of these concerns are considered and included in the assessment of changes in habitat, movement and mortality risk on the wildlife indicators. Community concerns regarding effects related to cultural and traditional land use, such as trapping and hunting, are addressed in Volume 5B.

Habitat Suitability and Effectiveness

Changes in habitat suitability and effectiveness for wildlife will result from the Project. Habitat loss and reduced habitat effectiveness can cause displacement of wildlife, and potentially result in the use of less suitable habitat, reduced foraging ability (Bird *et al.* 2004), increased energy expenditure (Jalkotzy *et al.* 1997) and lower reproductive success (Habib *et al.* 2007). The Project will have effects on wildlife habitat in general, and on site-specific habitat features such as mineral licks, nests and dens, ungulate forage and calving areas, wildlife trees, wetlands, watercourses and riparian areas (Wildlife Technical Report in Volume 5C). Avoidance of site-specific habitat features during construction was a recommendation shared by most Aboriginal communities during the wildlife field studies. Concerns related to disturbance of habitat for rare or sensitive species were communicated by Aboriginal communities, regulatory authorities, local biologists, and other stakeholders (*e.g.*, participants of ESA and Community Workshops). Given the importance of moose, deer and elk to maintaining a traditional lifestyle, changes in ungulate habitat are a primary concern for Aboriginal communities. Potential effects on wildlife habitat resulting from spills, leaks and contamination (*e.g.*, drilling fluid release) is also a concern for Aboriginal communities and other stakeholders.

Clearing activities during construction of the Project will alter habitat structure, and result in direct habitat loss or alteration. Operations of the Project will also require ongoing vegetation management, resulting in the maintenance of forest habitat in earlier seral stages (herbaceous and shrub stages) until the pipeline is abandoned and the disturbed areas are reclaimed. Clearing of the construction right-of-way and temporary workspace will reduce cover availability for wildlife and temporarily reduce forage availability. As cleared areas regenerate with early seral vegetation, forage availability will increase for some species (*e.g.*, browse for moose and deer; increased berry production for bears and some bird species). The *Guidelines for Evaluating, Avoiding and Mitigating Impacts of Major Development Projects on Wildlife in British Columbia* (Harper *et al.* 2001) identify pipeline projects as having a negative effect on vegetation and, therefore, wildlife habitat, due to complete removal or modification of the original vegetation pattern and subsequent change in ecosystem dynamics (*i.e.*, changes in microclimate, ground cover, soil compaction). The negative habitat effects for most wildlife species are considered within these guidelines to be minor unless a substantial portion or critical element of the habitat was rendered unsuitable by the development. Further, the creation of a small portion of young seral habitat, in most cases, is not expected to influence most wildlife populations, and may result in habitat enhancement effects for some species (Harper *et al.* 2001).

Indirect habitat loss or alteration occurs when habitat is available but the quality or effectiveness of the habitat is changed such that wildlife avoids the habitat or reduce their use of it. Reduced habitat effectiveness can occur as a result of fragmentation, creation of edges, or sensory disturbance (*e.g.*, noise, artificial light, proximity to facilities and infrastructure, human activity and traffic). Habitat fragmentation can cause habitat to become unsuitable for species with large territories or home ranges, alter predator-prey dynamics and allow for increased invasive or parasitic species abundance (*e.g.*, cowbird parasitism of songbird nests near forest edges). Changes in habitat suitability may also result from changes in vegetation communities due to increased light penetration at clearing edges that causes increased understory vegetation growth, or from changes in water quality (*e.g.*, sedimentation, deposition of airborne contaminants).

The three main components of habitat fragmentation are habitat loss, reduced habitat patch size and increased isolation of patches (Andrén 1994). Habitat fragmentation has the potential to alter species abundance and distribution over the landscape by affecting predation and brood parasitism, altering microclimate, decreasing food, and reducing ability of animals to move between habitat patches within a landscape (Swift and Hannon 2010). Short and long-term declines of various species of forest birds have been attributed to the reduction and fragmentation of forest cover (Lynch and Whigham 1984, Sekercioglu *et al.* 2002, Schmiegelow and Mönkkönen 2002), although the term fragmentation has been used inconsistently. Precise determination of the actual magnitude and significance of forest fragmentation is made difficult by virtue of the interaction between a given bird species and factors such as: residual patch size; dynamics, duration and nature of habitat loss (*e.g.*, agricultural, urban/industrial, fire, forestry); species specialization; and presence of parasitic or generalist predators (*e.g.*, brown-headed cowbird, crows) (Schmiegelow *et al.* 1997, Schmiegelow and Mönkkönen 2002). Since the effects of habitat loss, reduced patch size, and increased isolation of patches act cumulatively, it is difficult to disentangle their effects.

Sensory disturbance such as noise and light can reduce habitat effectiveness. Noise associated with anthropogenic activities can reduce the effectiveness of habitat for wildlife. Construction, maintenance activities and operations of the pipeline and associated facilities will result in elevated noise levels that may reduce habitat effectiveness for some species. Different species, and even individuals within a species, are expected to respond differently to noise disturbances. Various factors affect an animal's response to noise, such as noise level, frequency distribution, duration, number of events, rate of onset, level of existing ambient noise, time of year or day, animal activity and location, animal age and gender. Noise effects on wildlife can potentially include habitat loss through avoidance, increased energy expenditure, changes in normal behaviours (*e.g.*, feeding) and impaired communication between individuals.

The assessment of potential Project effects on habitat suitability and effectiveness is supported by quantification of predicted changes in effective habitat. Habitat models were used to identify habitat suitability within the Wildlife LSA, predict changes in habitat effectiveness as a result of the Project and other developments, support development of appropriate mitigation measures, and inform the evaluation of significance of Project effects on habitat. Model results do not represent actual wildlife use of habitats, but provide a characterization of habitats in the Wildlife LSA most likely to be used by a given indicator based on habitat variables that have been demonstrated or deemed likely to affect suitability and effectiveness. Some species may avoid or reduce habitat use in proximity to human disturbance even if suitable habitat features are present. This is considered indirect habitat disturbance, or a reduction in habitat effectiveness. The area of avoidance or reduced use in proximity to disturbance is often referred to as a zone of influence (ZOI), which varies depending on the species sensitivity, the type, intensity and duration of the disturbance, and the ability of the surrounding habitat to buffer the disturbance (*e.g.*, topography and vegetation). Suitability ratings were adjusted within ZOI relevant to the modelled species and disturbance type, where appropriate, such that the resultant habitat suitability rating decreases closer to anthropogenic disturbance. This puts the suitability ratings in context and equates to a habitat effectiveness rating. For ease of description, habitat rated moderate to high is referred to as ‘effective’ habitat in this assessment. Habitat models will be updated upon completion of Terrestrial Ecosystem Mapping for the Project in 2014, where warranted. The conclusions of the assessment are not expected to change substantially as a result.

By their nature, all habitat models are limited by the accuracy and resolution of the data input. The results of habitat models for this assessment are not expected to be exact characterizations of habitat effectiveness for every wildlife species potentially occurring in the Wildlife LSA, but are considered appropriate for assessing changes in habitat, evaluating the significance of these changes, and informing development of mitigation. The Wildlife Habitat Modelling and Species Accounts Technical Report in

Volume 5C provides further details on habitat modelling methods, including evaluation of model reliability and confidence.

Movement

Project construction and operations can alter wildlife movement by reducing habitat connectivity and creating barriers or filters to movement. A disturbance is considered a barrier when no movement occurs across it, or a filter if the rate of movement through the disturbance is less than it would be through intact habitat (Jalkotzy *et al.* 1997). Habitat fragmentation results when barriers to movement cause functional separation of habitats into smaller, isolated habitat patches (Andrén 1994, Jalkotzy *et al.* 1997). Species that have late age of first reproduction, low population densities, low reproductive rates, large home ranges, low fecundity, and move over large distances to disperse, find food and mate, display low resilience to habitat fragmentation (Dunne and Quinn 2009). Compiled ATK and TEK shared during field studies and engagement identified disruption of wildlife movement during construction as an important consideration for Project effects. In particular, Aboriginal communities advised that identified game trails be kept open during construction, and disturbance within riparian areas be avoided by implementing buffers to prevent barriers to wildlife movement that could block access to important habitats (*e.g.*, food and water sources) (Wildlife Technical Report of Volume 5C).

Wildlife movement patterns vary between species, with species-specific attributes such as size and life stage, and other factors such as time of day and season. Many species will alter their movements to avoid areas with high levels of human activity and development. However, some species may be less affected by anthropogenic disturbance and use established trails that are habitually used for movement, regardless of proximity to human activity and development. In some cases, linear developments have been shown to block, delay or deflect ungulate movements, potentially restricting or reducing access to some parts of their range (Harper *et al.* 2001). Studies on small mammal movements in forested habitat have concluded that pipeline rights-of-way may act as barriers or filters to movement of flying squirrels, red squirrels and marten (Marklevitz 2003). Changes in movement patterns can also occur since some wildlife species may be attracted to linear corridors as travel routes. For example, wolverines have been found to diverge from their line of travel under forest cover when linear corridors with compacted snow were encountered, in order to follow the linear corridors, which provided easier travel routes (Wright and Ernst 2004). Changes in movement patterns may also occur as some species are attracted to early seral vegetation in regenerating areas. Species that prefer edges and habitat generalists are most likely to use disturbed areas (Jalkotzy *et al.* 1997).

Mortality Risk

This subsection addresses the anticipated effects of Project construction and operations on wildlife mortality risk. Given the difficulty in quantifying the variables potentially affecting wildlife mortality risk, this issue was assessed qualitatively. Minor spills during construction are typically readily contained and cleaned up, and are not expected to affect wildlife mortality risk. Pipeline spill scenarios are addressed separately in Volume 7.

Compiled ATK and TEK and shared during field studies identified concerns related to wildlife mortality risk associated with traffic and construction equipment, new access for hunters, predation on the cleared pipeline right-of-way (changes in predator-prey dynamics), and increased human-wildlife conflicts.

The Project has potential to increase wildlife mortality risk during construction as a result of wildlife collisions with vehicles or equipment, loss or disruption of habitat (*e.g.*, nests, dens, overwintering sites) and sensory disturbance (*e.g.*, nest abandonment). As noted above, wildlife mortality risk may be affected during Project operations as a result of changes in predator/prey dynamics. Linear corridors can increase the risk of mortality for some species by attracting prey species to early seral vegetation establishing on the disturbance, improving access and increasing sight-lines, which may lead to increased predator efficiency. Studies have found that linear corridors are attractive to predators as easy travel routes (James 1999, Stuart-Smith *et al.* 1997, Thurber *et al.* 1994) and may affect predator-prey dynamics (Bergerud *et al.* 1984, Edmonds and Bloomfield 1984, Rohner and Kuzyk 2000). James (1999) found that wolves traveled 2.9 times faster on linear corridors. Higher rates of travel may increase the encounter rates between predators and their prey, resulting in more frequent kills. Wolf hunting behaviour is suggested to potentially change when landscapes are altered by industrial development, which may affect predation risk (Kuzyk 2002).

Similarly, linear corridors potentially affect wildlife mortality risk from trapping, hunting and poaching due to access development, since these activities are often associated with roads or other linear corridors that create access (Collister *et al.* 2003, Wiacek *et al.* 2002).

7.2.10.6 Mitigation Measures

Pipeline corridor and site selection is the primary mechanism for avoiding or reducing Project effects on wildlife. Criteria used throughout the corridor and site selection process are described in detail in Volume 4A. In particular, the following corridor and site selection criteria were selected in part to minimize Project effects on wildlife:

- where practical, follow existing linear disturbances (*i.e.,* pipeline, utility, seismic and road rights-of-way) to avoid or minimize fragmentation of habitat;
- use existing clearings (*i.e.,* shared workspace) to reduce the amount of new clearing and land disturbance required;
- avoid or reduce length traversing environmentally sensitive areas such as parks, protected areas, endangered or sensitive vegetation and wildlife habitat, and other environmentally sensitive areas, where practical;
- avoid, to the extent practical, areas of undisturbed native vegetation by maximizing the use of previously cleared lands or lands currently under industrial land use;
- use of existing access, to the extent feasible; and
- avoid, to the extent practical, known locations that provide site-specific habitat for wildlife species of concern or apply site-specific mitigation.

Mitigation measures for avoiding or reducing Project effects on wildlife are presented in Table 7.2.10-3. The recommended timing/least risk windows and setback distances presented in Table 7.2.10-3 are in place to reduce disturbance to wildlife during sensitive periods. Various circumstances that may be encountered during Project construction or operations have been considered and included in the recommended mitigation. In the event there are conflicts between the timing/least risk windows and the construction schedule (*i.e.*, once the final route alignment has been determined and the construction schedule has been finalized), Trans Mountain will consult with the appropriate regulatory authorities to develop appropriate mitigation. Pre-construction wildlife surveys may be conducted to collect information needed to inform mitigation planning.

The recommended mitigation measures provided in Table 7.2.10-3 were developed in accordance with industry and regulatory guidelines, including relevant recommendations in land use planning documents (Appendix E in the Wildlife Technical Report of Volume 5C), in addition to:

- *Environmental Protection and Management Guide* (BC OGC 2013);
- *Approved Ungulate Winter Ranges - Approved Objectives/General Wildlife Measures* (BC MOE 2013c);
- *Approved Wildlife Habitat Areas – Approved Orders/General Wildlife Measures* (BC MOE 2013d);
- *Guidelines for Raptor Conservation during Urban and Rural Land Development in British Columbia* (BC MOE 2013e);
- *Develop with Care 2012* (BC MOE 2012a);
- *Environmental Protection and Management Regulation* under the *Oil and Gas Activities Act* (BC Reg 200/2010);
- *Standards and Best Practices for Instream Works* (BC MWLAP 2004a);

- *Accounts and Measures for Managing Identified Wildlife* (BC MWLAP 2004b);
- *Best Management Practices for Amphibians and Reptiles in Urban and Rural Environments in British Columbia* (BC MWLAP 2004c);
- *Draft Gastropod Best Management Practices Guidebook, Oregon Forest snail and Other Land Snails at Risk in the Coastal Lowlands* (BC MOE 2007);
- *Best Management Practices Guidelines for Pacific Water Shrew in Urban and Rural Areas* (Craig *et al.* 2010);
- *Guidelines for Evaluating, Avoiding and Mitigating Impacts of Major Development Projects on Wildlife in British Columbia* (Harper *et al.* 2001);
- *Integrated Standards and Guidelines for the Enhanced Approval Process* (Government of Alberta 2013a);
- *Recommended Land Use Guidelines for Protections of Selected Wildlife Species and Habitat within Grassland and Parkland Natural Regions of Alberta* (ASRD 2011a);
- Wildlife Sensitivity Maps, ASRD Digital Spatial Data Layers (AESRD 2013d);
- *Incidental Take of Migratory Birds in Canada* (Environment Canada 2013e);
- *Environmental Assessment Best Practice Guide for Wildlife at Risk in Canada* (Canadian CWS 2004);
- *Petroleum Industry Activity Guidelines for Wildlife Species at Risk in the Prairie and Northern Region* (Environment Canada 2011a);
- relevant recovery planning documents (BC MOE 2013f); and
- *Canadian Council on Animal Care species-specific recommendations on: amphibians and reptiles* (Canadian Council on Animal Care n.d.).

TABLE 7.2.10-3

RECOMMENDED MITIGATION FOR WILDLIFE AND WILDLIFE HABITAT

Concern	Province/Location	Recommended Mitigation[1]
Habitat Loss/Alteration	Alberta/BC	• Avoid activity during sensitive time periods for wildlife species to the extent feasible. • Share workspace with the adjacent existing TMPL right-of-way or other existing rights-of-way where practical to reduce the construction right-of-way-width. • Do not clear timber, stumps, brush or other vegetation beyond the marked construction right-of-way boundary. • Where grading is not required, cut/mow/walk down shrubs and small diameter deciduous trees at ground level to facilitate rapid regeneration. • Use natural recovery as the preferred method of reclamation on level terrain and at wetlands unless otherwise requested by the regulator and where bio-engineering (*e.g.*, shrub staking/planting) will be conducted. • Plant native tree seedlings and/or shrubs at select locations to be determined in the field by the Environmental Inspector, in consultation with the Wildlife Resource Specialist. • Avoid the use of pesticides (except for herbicides to control invasive plants or noxious weeds; only use as spot treatments and outside the migratory bird breeding season) (BC MOE 2012a). • Reduce the width of grubbing near watercourses, wetlands and through other wet areas to facilitate the restoration of shrub communities. • Reduce disturbance at riparian areas, and where practical, extend the riparian buffer by implementing trenchless pipeline crossing techniques, or cut/mow/walk down shrubs and small diameter deciduous trees at ground level to facilitate rapid regeneration. • Limit vegetation control along the right-of-way and allow natural regeneration during the operations phase to the extent feasible. • Conduct pre-construction surveys to identify site-specific habitat features (*e.g.*, mineral licks) and implement the appropriate setbacks and/or timing windows.

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Access and Line-of-Sight Management	Alberta/BC	• Implement the measures included in the Traffic and Access Control Management Plan prepared for the Project (Appendix C of the Pipeline EPP). • Implement measures to reduce access (human and predator) along the right-of-way following construction. Measures may include but are not limited to planting tree seedlings and/or shrubs in select locations to facilitate rapid regeneration of natural vegetation, and blocking access entry points by mounding, rollback, boulder barriers, earth berms or locked gates. The locations of access control measures along the right-of-way will be determined in consideration of consultation with provincial regulatory authorities. • Where rollback and coarse woody debris are needed for access management, erosion control and habitat enhancement, ensure that a sufficient supply is set aside for this purpose during final clean-up. • Consider the following at the proposed crossing of roads, railways, other pipelines or watercourses: extend the length of an HDD or bored crossings where this crossing technique has been proposed to leave a vegetated screen and/or narrow the right-of-way width if feasible. • Use existing roads to access the pipeline right-of-way. Deactivate and reclaim any temporary roads that are no longer needed with native vegetation. Implement measures to reduce access (human and predator) along these temporary roads, as required. • Install educational signs as needed at selected locations.
Barriers to Wildlife Movement	Alberta/BC	• Conduct work as expeditiously as practical (*i.e.,* interval between front-end work activities such as grading and back-end activities such as clean-up) to reduce the length and duration of the open trench and to reduce potential barriers and hazards to wildlife. • Locate gaps in pipe to allow wildlife movement in places that also facilitate construction such as at slope changes, crossings (*i.e.,* watercourse, road, pipeline right-of-way, railway) and bends. The locations of the gaps should coincide with gaps in spoil, slash piles and snow windrows. The locations can be determined in the field by the Environmental Inspector. • Restore habitat connectivity by redistributing large-diameter slash (rollback) over select locations on the pipeline right-of-way (*e.g.*, where high levels of coarse woody debris occur prior to construction), to provide cover and facilitate movement of wildlife (*e.g.*, furbearers). Specific locations are to be determined in the field by the Environmental Inspector and Wildlife Resource Specialist in discussion with provincial regulatory authorities.
Wildlife Disturbance and Attraction of Wildlife During Construction	Alberta/BC	• Schedule clearing and construction activities to avoid sensitive wildlife timing windows wherever feasible. • Minimize traffic and prohibit recreational use of all-terrain vehicles or snowmobiles by construction personnel on the pipeline right-of-way and at facilities. • Prohibit personnel from having pets on the pipeline right-of-way and at facilities. • Prohibit personnel from feeding or harassing wildlife. • Obey speed limits along access roads and the right-of-way. • Ensure that food waste and industrial waste are disposed of properly. • Report any issues related to wildlife encountered during construction and operations to the Environmental Inspector, who will report it to the appropriate regulatory authorities. • Implement the measures in the Wildlife Conflict Management Plan to prevent human/wildlife conflict and wildlife mortality (Appendix C of the Pipeline and Facilities EPPs).
Sensory Disturbance	Alberta/BC	• Use low lighting and/or task lighting (*e.g.,* downturned shaded fixtures to prevent sky-lighting or bird disorientation), and a higher lumen/watt ratio at all new facilities or facility expansions. • Comply with appropriate regulatory requirements related to noise during construction and operations of facilities to minimize disturbance related to noise.
Migratory Birds	Alberta/BC	• In Alberta, schedule clearing and construction activities outside of the migratory bird restricted activity period (RAP) of May 7 to August 20. Wetlands attractive to migratory birds should not be cleared/disturbed from April 20 to August 25 (Gregoire pers. comm.). In the event clearing or construction activities are scheduled during the migratory bird RAP, follow the measures for conducting migratory bird nest sweeps described below. • In BC, schedule clearing and construction activities outside the migratory bird breeding season of March 15 to August 15 (Wilson pers. comm.). In the event clearing or construction activities are scheduled during the migratory bird breeding season, follow measures for conducting migratory bird nest sweeps described below.

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Migratory Birds (cont'd)	Alberta/BC	• In simple habitat types where active nests are easier to locate (*i.e.,* previously cleared areas and open areas with sparse vegetation and few trees), a nest sweep may be completed within 7 days of activity that is scheduled to occur within the migratory bird RAP. Use non-intrusive methods to conduct an area search for evidence of nesting (*e.g.,* presence of singing birds, territorial males, alarm calls, distraction displays). In the event an active nest is found, it will be subject to site-specific mitigation measures (*i.e.,* clearly marked protective buffer around the nest and/or non-intrusive monitoring). • In complex habitats where active nests are more difficult to find (*e.g.,* forests), it is recommended that pre-clearing be conducted. If this is not feasible and activity is scheduled to occur within the migratory bird RAP, contact Environment Canada prior to activity to discuss the area to be cleared. Use non-intrusive methods to conduct an area search for evidence of nesting (*e.g.,* presence of singing birds, territorial males, alarm calls, distraction displays). In the event an active nest is found, it will be subject to site-specific mitigation measures (*i.e.,* clearly marked protective buffer around the nest and/or non-intrusive monitoring). • In BC, in the event that an active Williamson's sapsucker or Lewis's woodpecker nest tree is found within or adjacent to the Project Footprint, consult with BC MFLNRO to discuss practical options and mitigation strategies. • Consider implementing the following bird conservation strategies: for Lewis's woodpecker, retain cavity-bearing trees and snags as nesting habitat, initiate nest box programs in areas lacking cavities/snags, restore/expand riparian buffers (minimum 30 m and >300 m for at least 10% of stream length) where nests are found; for American white pelican, double-crested cormorant and Western grebe establish undisturbed buffer zones (100 m) around breeding colonies; for rusty blackbird maintain unharvested buffers of contiguous forest around bogs used for breeding; and for barn swallow avoid the use of pesticides to maintain invertebrate species (Environment Canada 2013f).
Key Wildlife and Biodiversity Zone	Alberta • North Saskatchewan River: RK 32.7 to RK 34.1 for approximately 1.4 km • North Saskatchewan River: RK 36.7 to RK 37.1 for approximately 0.4 km • Athabasca River: various locations between RK 307.4 to RK 311.6 for approximately 3.8 km	• Schedule clearing, construction and clean-up activities outside the timing restriction of January 15 to April 30. All activities within 100 m of existing arterial all-weather roads can be initiated at any time provided ground conditions are favourable and may continue until adverse ground conditions are encountered (Government of Alberta 2013a). Consult with AESRD if construction activity is scheduled within this period to to discuss practical options and mitigation strategies. • Conduct work as expeditiously as practical (*i.e.,* interval between front-end work activities such as grading and back-end activities such as clean-up) to reduce the length and duration of the open trench and to reduce potential barriers and hazards to wildlife.
Special Access Zone	Alberta • RK 286.8 to RK 292.6 (approximately 5.8 km) • RK 329.0 to RK 339.4 (approximately 10.4 km) • Hinton Pump Station	• Use existing roads to access the pipeline right-of-way and the Hinton Pump Station where practical. If new access is required, construct to minimal disturbance standards (Class V), unless the new access is less than 100 m to an existing arterial all-weather road, in which case, the new access can be developed using Class III to Class V roads (all-weather or dry tertiary; frozen; minimal disturbance) (Government of Alberta 2013a). If new access, which is attached to the existing arterial all-weather access road, is greater than 100 m in distance from the arterial all-weather access road, then access control is required to restrict unauthorized traffic at all stages of construction, operation, deactivation and reclamation of the road. The access control will be placed within 100 m distance from the start of the new access (Government of Alberta 2013a). • Avoid creating access routes as loops and design to dead-end (Government of Alberta 2013a). • Consult with AESRD on the use of rollback along the pipeline right-of-way within this zone. • Revegetate any areas that were cleared (pipeline right-of-way, roads, facilities) with species compatible to the adjacent vegetation type. Do not seed with species that are palatable to wildlife (*i.e.*, legumes) (Government of Alberta 2013a).

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Grizzly Bear Zone	Alberta • RK 297.2 to RK 339.4 (approximately 42.2 km) • Hinton Pump Station	• Apply measures noted for Special Access Zones to limit new access. • All workers will receive Bear Awareness Training (Government of Alberta 2013a). • Coordinate access and new clearing requirements with other industrial users in the area to minimize human activity within grizzly bear habitat (Government of Alberta 2013a). • Delimb coniferous trees and leave limbs on-site, where practical, to provide a seed source (Government of Alberta 2013a). • Prohibit construction personnel from feeding or harassing wildlife. Dispose of food wastes and industrial waste properly. • Utilize multi-passenger vehicles for the transport of crews to and from the job sites, to the extent practicable, to reduce traffic during construction. • Follow the *Bear-Human Conflict Management Plan for Camps* provided in the *Integrated Standards and Guidelines* if a camp is located within grizzly bear habitat (Government of Alberta 2013a). • In the event an active grizzly bear den is found, contact AESRD to discuss mitigation strategies. Recommended setbacks are 750 m for high disturbance activities (*i.e.*, conventional pipelines) and 500 m for medium disturbance activities (*i.e.*, conventional pipeline parallel to a linear corridor) from October 1 to April 30 (Government of Alberta 2013a).
Trumpeter Swan Waterbodies/Watercourses	Alberta • Unnamed Lake (locally referred to as Lacy's Lake) at SW 22-53-18 W5M: approximately 400 m north of RK 242 • Annabel Lake at 34-52-19 W5M: approximately 700 m south of RK 254 • Unnamed waterbody at W 5-53-19 W5M: approximately 200 m north of RK 258	• Schedule clearing, construction and clean-up activities outside the timing restriction of April 1 to September 30 within 800 m of a trumpeter swan waterbody/watercourse. In the event activity is scheduled during this period and a breeding pair (with cygnets) is nesting on the waterbody, consult with AESRD to discuss practical options and mitigation strategies. • Avoid direct aerial overflights over identified trumpeter swan waterbodies/watercourses that have a breeding pair (with cygnets) from April 1 to September 30 (*e.g.*, low-level flights over the nest, circling the nest) (Government of Alberta 2013a).
Sensitive Raptor Range - Bald Eagle	Alberta • RK 0.0 to RK 68.8 (approximately 68.8 km) • Edmonton Terminal	• Recommended setbacks from bald eagle nests include: for high disturbance activities (*i.e.,* conventional pipeline), a 1,000 m setback is recommended year-round; for medium disturbance activities (*i.e.,* conventional pipeline parallel to a linear corridor), a 1,000 m setback is recommended from March 15 to July 15 and a 100 m setback is recommended from July 16 to March 14 (Government of Alberta 2013a). • In the event an active bald eagle nest is found, consult with AESRD to discuss practical options and mitigation strategies.
Sharp-Tailed Grouse Lek	Alberta • In Alberta, a provincially identified sharp-tailed grouse range occurs from RK 0.0 to RK 68.8 (approximately 68.8 km) BC	• In Alberta, implement a 500 m setback in the event an active sharp-tailed grouse lek is identified. Use noise reduction equipment to muffle or otherwise control noise so that operational noise does not exceed 49 decibels measured at 10 m from the source to the 500 m setback (Government of Alberta 2013a). In the event an active sharp-tailed grouse lek is found, consult with AESRD to discuss practical options and mitigation strategies. • In BC, avoid activity in the area of identified sharp-tailed grouse leks from April 1 to May 31 (Surgenor pers. comm.). Activities are not recommended within 400 m of a sharp-tailed grouse lek between April 1 and May 31 (BC MWLAP 2004b). In the event an active sharp-tailed grouse lek is identified, consult with BC MFLNRO to discuss practical options and mitigation strategies.
Protective Notations (PNT)	Alberta • PNT 980061 at NW 13-53-6 W5M (approximately RK 118.1 to RK 118.9) • PNT 870456 at NW 22-53-10 W5M (approximately RK 161.0 to RK 161.8)	• Consult with AESRD in regards to activity in PNT 980061 (Fragmented Land Pattern) and 980160 (Research Site Structure). • Maintain tree cover and minimize new clearing requirements in PNTs 870456 (Ungulate Winter Range) and 780290 (Fish and Wildlife Resource Management Area) by paralleling the existing TMPL right-of-way (Hobson pers. comm.). • Routing has avoided the long-toed salamander breeding ponds by 100 m in PNT 020232 (Rare and Endangered Species Habitat Protection Area for long-toed salamander). Traffic should be reduced within the area of the ponds in spring and early fall to reduce mortality during salamander breeding and dispersal periods (Wilkinson pers. comm.).

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]

Mountain Caribou Range
 	
Includes Ungulate Winter Range U-3-004 (Modified Harvest Zone) for the Wells Gray Caribou Range
	BC
	• Wells Gray Caribou Range (various locations for approximately 30.7 km from RK 550.1 to RK 602.6; includes 4.3 km within UWR U-3-004)
	• Groundhog Caribou Range (various locations for approximately 10.3 km from RK 629.8 to RK 649.4)
		• Align route to parallel existing corridors (existing TMPL right-of-way, Highway 5, existing power line) to the extent feasible to reduce habitat disturbance.
		• Work with the appropriate regulatory authorities for deviation from the General Wildlife Measures set out in the Order for Wells Gray caribou Ungulate Winter Range (U-3-004).
		• Avoid activity in early to mid-winter within caribou range (*i.e.*, November 1 to January 15) (Surgenor pers. comm.), to the extent feasible.
		• Implement line-of-sight breaks every 500 m along segments not sharing a right-of-way boundary with another linear corridor such as a road or power line. Line-of-sight measures may include: bends in the right-of-way; doglegs at intersections with access roads; woody debris or earth berms; tree or shrub planting to create vegetation screens across the right-of-way; avoiding clearing on the right-of-way (*e.g.*, HDD or bored crossings of watercourses, roads or other rights-of-way).
		• Avoid creating early seral habitat that will provide forage for moose (*e.g.*, do not plant willow or red osier dogwood) (Surgenor pers. comm.).
		• Avoid creation of new access within caribou range where feasible. Use existing roads/linear corridors for access whenever practical (BC OGC 2013). Where practicable, avoid building roads within 100 m of an existing trail (Kamloops LRMP Mountain Caribou Subcommittee 2006).
		• Deactivate and reclaim all temporary construction access within caribou range (Kamloops LRMP Mountain Caribou Subcommittee 2006).
		• Coordinate any new access with all users and consider caribou management issues (*i.e.,* seasonal use of the road) (Kamloops LRMP Mountain Caribou Subcommittee 2006).
		• Minimize winter road use and, where feasible, coordinate with other activities such as winter logging (Kamloops LRMP Mountain Caribou Subcommittee 2006).
		• Conduct work expeditiously to maintain a tight construction spread (*i.e.,* interval between front-end work activities such as grading and back-end activities such as clean-up) to reduce the duration of the open trench and to reduce potential barriers and hazards to wildlife.
		• Locate gaps in pipe to facilitate wildlife movement in places that also facilitate construction such as at slope changes, crossings (*i.e.,* watercourse, road, pipeline right-of-way, railway) and bends. The locations of the gaps should coincide with gaps in spoil, slash piles and snow windrows. The locations can be determined in the field by the Environmental Inspector.
		• Where segments of the right-of-way require rollback for access management or erosion control, ensure sufficient timber is set aside for this purpose during final clean-up.
		• Implement minimum surface disturbance construction techniques that will facilitate natural revegetation in areas where grading or blasting is not required in areas of upland deciduous and mixedwood forests and in graminoid and shrub-dominated wetland communities.
		  – Minimize the width of the pipeline right-of-way to the extent practical by utilizing shared workspace, avoiding clearing large diameter trees on the edge of the right-of-way; minimizing extra temporary workspace (*e.g.*, place log decks, storage areas, other temporary construction areas outside of UWR U-3-004).
		  – Maintain root layer integrity on the right-of-way by clearing vegetation above ground level and restricting grubbing to the trench width.
		  – Protect travel and work surfaces by packing snow (during winter) to protect soils and vegetation where practical.
		• Avoid using seed mixtures that will attract other ungulates (deer, moose) during reclamation (Hoekstra pers. comm.).
		• Implement measures to reduce access (human and predator) along the pipeline right-of-way following construction. Measures include using woody debris as rollback, mounding, planting trees and/or shrubs for visual screens, and rock piles or berms across the right-of-way. The locations of access control measures along the pipeline right-of-way will be determined in consideration of consultation with provincial regulatory authorities.
		• Consider the following at the proposed crossing of roads, other pipelines or watercourses: extend the length of HDD or bored crossings where this crossing method has been proposed to leave a vegetated screen for line-of-sight and/or narrow the right-of-way width if feasible.
		• Monitor the effectiveness of access control measures and reclamation during post-construction environmental monitoring. Implement remedial measures if warranted. Schedule remedial work outside of the period of early to mid-winter when caribou are more likely to be in the area.

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Mountain Caribou Range Includes Ungulate Winter Range U-3-004 (Modified Harvest Zone) for the Wells Gray Caribou Range (cont'd)	See above	• Limit vegetation control along the right-of-way and allow natural regeneration during the operations phase to the extent feasible. • Limit operational access along the pipeline right-of-way within caribou range. • Report any sightings of caribou during construction and operations to Trans Mountain's Lead Environmental Inspector or Environmental Inspector(s).
Ungulate Winter Range for Mule Deer (U-3-003)	BC • Various locations for approximately 36.7 km from RK 891.6 to RK 969.6 • Kingsvale Pump Station (expansion) • Kingsvale Power Line (6.2 km)	• A timing window does not apply to this UWR (Surgenor pers. comm.). • For the proposed Kingsvale power line and pipeline right-of-way, minimize the right-of-way width to the extent practical by utilizing shared workspace, avoid clearing large diameter trees on the edge of the right-of-way; minimizing extra temporary workspace (*e.g.*, placing log decks, storage areas, other temporary construction areas outside of the UWR). Maintain root layer integrity on the right-of-way by clearing vegetation above ground level and restricting grubbing to the trench, to the extent practical. Avoid creation of new access. Use existing roads/linear corridors for access wherever practical. Deactivate and reclaim all temporary access. Implement measures to reduce access (human and predator). Measures include using woody debris as rollback, and planting trees and/or shrubs at select locations. • Work with the appropriate regulatory authorities for deviation from the General Wildlife Measures set out in the Ungulate Winter Range Order.
Ungulate Winter Range for Mule Deer and Columbian Black-Tailed Deer (U-2-006)	BC • Approximate 1.3 km segment from RK 1029.6 to RK 1030.9	• Work with the appropriate regulatory authorities to discuss the General Wildlife Measures set out in the Ungulate Winter Range Order. The measures may not be applicable to exploration, development and production activities when these activities have been authorized by the *Pipeline Act*.
Wildlife Habitat Area for Williamson's Sapsucker (3-143)	BC • Kingsvale Power Line (952 m)	• Conduct a survey to confirm status and presence of nest trees along the proposed Kingsvale power line right-of-way. In the event an active nest tree is found, consult with BC MFLNRO to discuss practical options and mitigation strategies. • Schedule clearing and construction activities outside the breeding season of March 15 to August 31 to the extent feasible (BC MOE 2012b). • During operations, retain coarse woody debris and snags (if not deemed a hazard) on the power line right-of-way (to provide foraging habitat) where practical (BC MOE 2012b). • Avoid creation of new access, where feasible. Use existing roads/linear corridors for access wherever practical. Deactivate and reclaim all temporary access. • Avoid the use of pesticides (except for herbicides to control invasive plants or noxious weeds; only use as spot treatments and outside the breeding season of March 15 to August 31 (BC MOE 2012b). • Work with the appropriate regulatory authorities for deviation from the General Wildlife Measures set out in the Wildlife Habitat Area Order.
Sowaqua Spotted Owl WHA 2-498 (Long-Term Owl Habitat Area)	BC • Various locations for approximately 10.4 km from RK 1022.9 to RK 1038.2	• Align route to parallel existing corridors (*i.e.*, existing TMPL right-of-way, Highway 5) to the extent feasible to reduce habitat disturbance. • Do not clear timber, stumps, brush or other vegetation beyond the marked construction right-of-way boundaries. • Minimize the width of the pipeline right-of-way to the extent practical by utilizing shared workspace, avoid clearing large diameter trees on the edge of the right-of-way; minimizing extra temporary workspace (*e.g.*, placing log decks, storage areas, other temporary construction areas outside the Sowaqua Spotted Owl WHA). • Avoid clearing large wildlife trees/veteran trees and snags where feasible. Retain slow decaying tree species (*e.g.,* cedar) where feasible (Blackburn *et al.* 2009). • Place large coarse woody debris (diameters greater than 50 cm in dry ecosystems and 75 cm in wet ecosystems). Utilize the largest coarse woody debris available where this is not available. Avoid breaking coarse woody debris into sections smaller than 10 m where feasible (Blackburn *et al.* 2009). • Avoid creation of new access, where feasible. Use existing roads/linear corridors for access whenever practical. Deactivate and reclaim all temporary construction access. • Do not use pesticides within the Sowaqua Spotted Owl WHA (BC MOE 2011a). • Use natural regeneration strategies in harvest openings (Blackburn *et al.* 2009). • Prepare a detailed Mitigation Plan in consultation with BC MFLNRO's Spotted Owl Recovery Coordinator. • Work with the appropriate regulatory authorities for deviation from the General Wildlife Measures set out in the Wildlife Habitat Area Order.

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Important Bird Area	BC Douglas Lake Plateau (BC172) • RK 850.6 to RK 865.4 (14.8 km) • RK 885.8 to RK 888.8 (3.0 km) • RK 897.6.0 to RK 898.2 (0.7 km) • Kamloops Pump Station BC English Bay and Burrard Inlet (BC020) • RK 1183.2 to RK 1183.6 (400 m) • Westridge Marine Terminal	• Schedule clearing and construction activities outside the migratory bird breeding season of March 15 to August 15 (Wilson pers. comm.). In the event clearing or construction activities are scheduled during the migratory bird breeding season, follow measures for conducting migratory bird nest sweeps described below. • In simple habitat types where active nests are easier to locate (*i.e.,* previously cleared areas and open areas with sparse vegetation and few trees), a nest sweep may be completed within 7 days of activity that is scheduled to occur within the migratory bird RAP. Use non-intrusive methods to conduct an area search for evidence of nesting (*e.g.,* presence of singing birds, territorial males, alarm calls, distraction displays). In the event an active nest is found, it will be subject to site-specific mitigation measures (*i.e.,* clearly marked protective buffer around the nest and/or non-intrusive monitoring). • In complex habitats where active nests are more difficult to find (*e.g.,* forests), it is recommended that pre-clearing be conducted. If this is not feasible and activity is scheduled to occur within the migratory bird RAP, contact Environment Canada prior to activity to discuss the area to be cleared. Use non-intrusive methods to conduct an area search for evidence of nesting (*e.g.,* presence of singing birds, territorial males, alarm calls, distraction displays). In the event an active nest is found, it will be subject to site-specific mitigation measures (*i.e.,* clearly marked protective buffer around the nest and/or non-intrusive monitoring). • Conduct species specific surveys to identify important wildlife features for species known to occur in the Important Bird Area (*e.g.*, Douglas Lake Plateau: sharp-tailed grouse leks, burrowing owl burrows, Lewis's woodpecker or Williamson's sapsucker nest; English Bay and Burrard Inlet: bald eagle nests, great blue heron colonies). In the event these are found, consult with BC MFLNRO to discuss practical options and mitigation strategies.
Raptor Nest	Alberta/BC	• Schedule clearing and construction activities outside of sensitive time periods for raptors (provided below) to the extent feasible. In the event clearing is scheduled within these periods, in areas of suitable habitat, conduct raptor nest searches prior to clearing to locate active raptor nests. In the event an active raptor nest is discovered, consult with the appropriate regulatory authorities to discuss practical options and mitigation strategies. • In Alberta, implement the appropriate setback in the event an active nest of a sensitive raptor is found (*i.e.,* ferruginous hawk, bald eagle, golden eagle, prairie falcon, peregrine falcon). For high disturbance activities (*i.e.*, conventional pipeline), a 1,000 m setback is recommended year-round. For medium disturbance activities (*i.e.,* conventional pipeline parallel to a linear corridor), a 1,000 m setback is recommended from March 15 to July 15 and a 100 m setback is recommended from July 16 to March 14 (Government of Alberta 2013a). All other raptor nests (*e.g.*, red-tailed hawk) have a recommended 100 m setback when they are active (Government of Alberta 2013a). • In BC, eagle, peregrine falcon, gyrfalcon, osprey and burrowing owl nests are protected year-round by the BC *Wildlife Act* and may not be cleared. The *Guidelines for Raptor Conservation* (BC MOE 2013e) provides information on sensitive breeding and nesting time periods and buffers for raptor nests according to their tolerance to human disturbance. These buffers range from 50 m to 500 m depending on the surrounding land use and species. During the breeding season, an additional 100 m "quiet" buffer is recommended. Clearly mark the appropriate buffers with fencing to prevent access to the nest. • In BC, barn owl nests have the following recommended setbacks: 200 m (undeveloped) and 100 m (rural). During the breeding season, an additional 100 m "quiet" buffer is recommended (BC MOE 2013e). • If construction is unavoidable within the recommended year-round and breeding buffers, a Nest Management Plan addressing various mitigation (including nest monitoring during the breeding period) is recommended. • If construction activities require the removal of a raptor nest that is protected year-round under the BC *Wildlife Act* (*i.e.*, eagle, peregrine falcon, gyrfalcon, osprey and burrowing owl), Trans Mountain will work with the appropriate regulatory authorities to develop a Nest Removal Management and Compensation Plan. Upon confirmation the nest is inactive, nest removal should occur during the least risk window of August through December. When a nest is removed the installation of a replacement structure (*i.e.*, a platform on a pole or transplanted tree) should be erected in nearby suitable habitat (BC MOE 2013e).

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Great Blue Heron Nesting Colony	Alberta/BC	• Schedule clearing and construction activities outside of sensitive time periods for great blue heron (provided below), to the extent feasible. In the event clearing is scheduled within these periods, in areas of suitable habitat, conduct nest searches during the breeding season and prior to clearing to locate nesting colonies. In the event an active colony is discovered, discuss appropriate mitigation strategies with regulatory authorities, which may include establishing protective buffers during sensitive periods. • In Alberta, activities are not recommended within 1,000 m with the exception of Low and Medium impact activities (*i.e.*, conventional pipeline along existing linear disturbances) that may occur up to 100 m from a colony when construction occurs from September 1 and February 28 (Government of Alberta 2013a). • In BC, great blue heron nests are protected year-round under the BC *Wildlife Act*. The following are the recommended setbacks: 300 m (undeveloped), 200 m (rural), 60 m (urban) and a 200 m "quiet" buffer during the breeding season from the outer perimeter of all nesting trees. The least risk window is from September 1 to February 15 (BC MOE 2012a).
Stream-Dwelling Amphibian – Coastal Tailed Frog and Pacific Giant Salamander	BC • Coastal tailed frog: RK 965.8 to RK 1117 • Pacific giant salamander: RK 1067 to RK 1090	• Maintain a 30 m setback distance (core buffer) from streams identified as coastal tailed frog habitat, where disturbance is to be avoided, to the extent feasible. Minimize disturbance within an additional 20 m buffer extending beyond the core buffer (BC MOE 2012a), where feasible. • Maintain a 50 m setback distance (core buffer) from streams identified as Pacific giant salamander habitat, where disturbance is to be avoided, to the extent feasible. Minimize disturbance within an additional 30 m buffer extending beyond the core buffer (BC MOE 2012a), where feasible. • Place large coarse woody debris on the pipeline right-of-way after construction, from either the 30 m setback boundary of the streambank to 100 m distance from suitable (*i.e.,* known or likely to be occupied) streams for coastal tailed frog and Pacific giant salamander (BC MWLAP 2004b). • If a trenched stream crossing method is necessary, implement the following measures: – Use existing access to facilitate construction, where feasible. If no existing access is available, limit instream crossings to one vehicular/equipment crossing to install an appropriate temporary crossing to facilitate construction. Remove crossings following construction. – Limit riparian disturbance to the maximum extent feasible within 50 m of coastal tailed frog streams. Clear only the minimum workspace necessary to facilitate construction. Use hand clearing methods within 50 m of the stream. – Where slopes exceed 60%, riparian avoidance buffers should extend beyond the top of the ravine. – Clearly mark and/or fence off riparian buffers prior to clearing and construction. – Install and maintain appropriate erosion control measures to prevent sedimentation during and following construction. – Maintain stream flows throughout construction. – Following construction, reclaim disturbed riparian areas using best available techniques to encourage rapid regeneration of native riparian vegetation. Monitor and implement remedial measures, if warranted, to ensure riparian restoration is adequate. • Conduct an amphibian salvage prior to clearing and construction activities at known coastal tailed frog and Pacific giant salamander breeding locations. Adhere to the Best Management Practices for Amphibian and Reptile Salvages in BC (EDI Environmental Dynamics *et al. in prep*). Note that coastal tailed frog and Pacific giant salamander use the same stream year-round, therefore, this mitigation is applicable year-round. In the event that coastal tailed frogs and/or Pacific giant salamanders are identified on the pipeline right-of-way during construction, the following mitigation is recommended: – remove the frogs/salamanders to the closest suitable upstream habitat, if it is safe to do so; – ensure frogs/salamanders are not held for longer than necessary to move them to the closest suitable habitat; – ensure frogs/salamanders are not held for more than two to four hours under any circumstances; and – frogs/salamanders must be captured, held, transported and released humanely. • Use sediment control measures from *Standards and Best Practices for Instream Works* (BC MWLAP 2004a). • Review opportunities to enhance the habitat by planting/allowing native vegetation growth that provides a protective buffer along streams, and maintain stream habitat complexity (*i.e.*, a natural meandering channel with stabilized banks, and step-pool morphologies) (BC MWLAP 2004b).

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Amphibian Breeding Pond	Alberta/BC	• Schedule clearing and construction activities outside of the breeding and seasonal migration periods for amphibians, where feasible. In Alberta, this is generally mid-April to mid-June (Government of Alberta 2013a). In BC, this will vary depending on pipeline segment and can be from mid-April to mid-June (Hargreaves to Hope) and from February to late-July or August (Hope to Westridge) (Wind pers. comm.). • In Alberta, in the event that a western toad breeding pond is found, a year-round 100 m setback distance is recommended (Government of Alberta 2013a), while Environment Canada recommends a year-round 400 m federal setback distance for western toad breeding ponds and wintering sites (Environment Canada 2011a). • In Alberta, in the event a long-toed salamander breeding pond is found, a year-round 200 m setback distance (where new-cut is required) and a 100 m setback distance (when paralleling existing linear disturbance) is recommended (Government of Alberta 2013a). In reference to the long-toed salamander breeding pond at NW 33-49-26 W5M (RK 339.3) located approximately 30 m north of the Hinton Pump Station, AESRD will be consulted to discuss mitigation for both the proposed expansion of the pump station, as well as pipeline construction. For activity in the summer (breeding season), mitigation may include exclusion fencing, onsite monitors and relocation if warranted. • In BC, protect identified amphibian breeding ponds by implementing appropriate buffers (150 m undeveloped; 100 m rural; 30 m urban) (BC MOE 2012a). • If the proposed pipeline right-of-way is located within the recommended setback distance of an amphibian breeding pond, consult with the appropriate regulatory authorities to discuss practical options and mitigation strategies. • Apply standard wetland construction and reclamation mitigation (*e.g.*, minimal disturbance, recontouring, reclamation, monitoring and remedial measures) to support habitat reclamation as needed. • Use snow packing and mats to avoid excessive soil compaction in the proximity of wetlands and watercourses. • Maintain natural hydrology of streams and wetlands during clearing, construction and clean-up activities. • Install fencing around wetlands for clearing and construction activities scheduled during the amphibian breeding period (spring), where warranted, to protect important habitat (BC MWLAP 2004b). • Install fencing along construction workspace near identified breeding ponds to prevent dispersing amphibians from entering the construction zone and limit vehicular activity in spring and early fall to reduce effects during the breeding and dispersal periods (Wilkinson pers. comm.). All fencing installed during clearing and construction activities should be removed once they are no longer necessary to prevent barriers to amphibian movement following construction. • Reclaim borrow pits and avoid creating small artificial ponds by avoiding construction during wet conditions that would create excessive soil rutting; grade ruts in construction access and on the right-of-way where rutting cannot be avoided. • Do not mow/brush vegetation within wetland riparian (fringe) areas during operation. • Conduct an amphibian salvage prior to clearing and construction activities at known amphibian breeding pond locations. Ensure the appropriate permit is obtained. In BC, adhere to the *Best Management Practices for Amphibian and Reptile Salvages in BC* (EDI Environmental Dynamics *et al. in prep*).
Pacific Water Shrew	BC • RK 1064 to 1179; • Burnaby to Westridge (RK 0 to RK 3.6)	• Where feasible, implement the following measures where Pacific water shrew are identified: a 100 m buffer from the Pacific water shrew habitat should be established and clearly marked and fenced off to prevent access; replant native vegetation (shrubs and trees) within 30 m of the stream or wetland to replace any cleared vegetation; and where replanting is not feasible, coarse woody debris should be placed within 30 m of the stream or wetland to provide cover and foraging habitat (Craig *et al.* 2010). • If Pacific water shrew are identified, a capture and release may be required to temporarily/permanently relocate individual shrews.

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Oregon Forestsnail	BC • RK 1043.7 to RK 1179; • Burnaby to Westridge (RK 0 to RK 3.6)	• Avoid clearing during spring-early summer (March-June) when snails are most active on the surface and depositing eggs (BC MOE 2007). If clearing or construction occurs in spring, conduct a pre-construction survey in areas with high habitat suitability (*e.g.*, patches of stinging nettle, dense herbaceous vegetation with fringecup or other moisture-loving plants, riparian areas, or other suitable moist sites) in late March or early April to the end of June prior to vegetation clearing (BC MOE 2007). • If a snail is found, move it off the construction footprint. Install barrier fencing at the time of the survey to deflect movements of snails away from the construction footprint. Maintain the fencing until construction activities are complete (BC MOE 2007). • Restore riparian zones and natural drainage patterns as soon as practical after construction (BC MOE 2007). • Retain big leaf maples, especially large diameter trees, wherever feasible (BC MOE 2007). • Restrict heavy machinery and vehicles to the construction footprint (BC MOE 2007). • Clean machinery and boots prior to use to avoid introducing non-native species (BC MOE 2007). • Avoid compaction of soil, disturbance of herbaceous plants and removal of coarse woody debris (BC MOE 2007), to the extent practical. • Manage construction waste and pollutants to prevent contamination of snail habitat (BC MOE 2007). • During operations, retain coarse woody debris on the pipeline right-of-way, including large-diameter downed logs; limit vegetation control (mowing) to leave undisturbed patches of stinging nettle and other herbaceous vegetation where concentrations of snails or patches of high-quality habitat occur (BC MOE 2007). • If clearing of the right-of-way is needed for operations, use hand clearing methods and mechanical clearing rather than herbicides (BC MOE 2007).
Reptiles	BC	• In the event an active snake hibernacula is identified, implement a 150 m buffer (BC MOE 2012a), and avoid activity during the period of April 15 to September 30 (BC MWLAP 2004b), to the extent feasible. • Consult with BC MFLNRO to determine the location and need for additional site-specific mitigation measures (*e.g.*, exclusion fencing for the open trench or along vehicle travel lanes) at identified locations (*e.g.*, Lac du Bois Road) where there is high potential for encountering snakes (Grasslands Conservation Council of British Columbia 2009). • All workers will receive education prior to commencing work, which will include best practices for avoiding snakes and appropriate protocols in the event a snake is detected at the work site. Refer to the Wildlife Conflict Management Plan in Appendix C of the Pipeline EPP.
Bats	Alberta/BC	• In Alberta, roosts and hibernation sites of northern long-eared bats have a year round 300 m setback from high disturbance activities; 100 m setback from medium disturbance activities and a 50 m setback from low disturbance activities. (Government of Alberta 2013a). • In BC, protect bat roosts from disturbance by humans and other sensory disturbances (BC MOE 2012a). Implement a 125 m buffer from bat hibernacula (from October 1 to April 30 or maternity roost (from May 1 to August 31) (BC MWLAP 2004b). Consult with BC MFLNRO where disturbance of a hibernacula or maternity roost is unavoidable to discuss practical options and mitigation strategies. • Do not blast, remove rock or talus, or construct new roads in the area surrounding a hibernacula or maternity roost unless there is no other practical option. Consult with BC MFLNRO to discuss alternate mitigation (BC MWLAP 2004b). • Schedule blasting that may occur within 1 km of Keen's long-eared myotis maternity roosts and hibernacula, to occur outside the period from October 1 to May 31 (BC MWLAP 2004b). Consider applying this best practice to other bat species.
Mammal Dens	Alberta/BC	• Contact provincial regulatory authorities to discuss the appropriate mitigation in the event an active bear den is discovered on or near the work site. Mitigation may include establishing protective buffers, monitoring the den and/or modifying the construction schedule to avoid activity until the den is inactive. • In Alberta, in the event an active mammal den is found, a 100 m setback is recommended (Government of Alberta 2013a). A setback of 750 m for high disturbance activities (*i.e.*, conventional pipelines) and 500 m for medium disturbance activities (*i.e.*, conventional pipeline parallel to a linear corridor) from October 1 to April 30, is recommended in the event an active grizzly bear den is discovered (Government of Alberta 2013). • In BC, a setback of 50 m from active bear dens is recommended BC (BC OGC 2013).

TABLE 7.2.10-3 Cont'd

Concern	Province/Location	Recommended Mitigation[1]
Mineral Licks	Alberta/BC	• Implement a 100 m setback in the event a mineral lick is identified (Government of Alberta 2013a, BC OGC 2013). In the event that shifting/narrowing the pipeline right-of-way is not feasible to maintain the minimum setback from a mineral lick, consult with AESRD or BC MFLNRO to discuss practical options and mitigation strategies. • Maintain the integrity of trails to mineral licks and do not isolate from nearby escape cover (*e.g.*, dense forest) (BC MWLAP 2004b). • Avoid activities (*i.e.*, clearing, construction, helicopter overflights) near mineral licks during critical periods (May to November) (BC MWLAP 2004b), to the extent feasible. • Deactivate access roads as soon as practical (BC MWLAP 2004b). • Leave a gap in set-up pipe within the area of the mineral lick to allow wildlife to access the mineral lick. The locations of the gaps in strung pipe should coincide with gaps in strippings, spoil, snow and rollback windrows.
Beaver Dams/Lodges	Alberta/BC	• Notify DFO 14 days prior to beaver dam removal and ensure that the removals are conducted in accordance with conditions of DFO's Alberta Operational Statement for Beaver Dam Removal (DFO 2007a). • In BC, in the event that beaver dams or lodges will be disturbed, submit a notification to the appropriate regional Habitat Officer of the BC MFLNRO at least 45 days prior to beaver dam removal, as per Section 40 of the *Water Regulation*. Following this notification, obtain a Ministry of Natural Resource Operations Wildlife Sundry Permit to remove a beaver dam. Standards and best practices for beaver dam removal identified in the BC *Standards and Best Practices for Instream Works* (BC MWLAP 2004a) will be applied.
Species with Special Conservation Status	Alberta/BC	• In the event that a species with special conservation status is observed during construction, the appropriate regulatory authorities will be contacted to determine if additional mitigation measures are warranted. • Implement the Wildlife Species of Concern Discovery Contingency Plan in the event that wildlife species of concern are identified during construction.

Note: 1 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B), Facilities EPP (Volume 6C) and Westridge Marine Terminal EPP (Volume 6D).

7.2.10.7 Potential Residual Effects

For each of the wildlife indicators, the identified potential effects associated with the construction and operations of the Project are:

- change in habitat;
- change in movement; and
- increased mortality risk.

The mitigation measures identified in Table 7.2.10-3 are expected to reduce the potential residual effects of the Project on wildlife and wildlife habitat. However, given the nature of the Project, effects on wildlife and wildlife habitat cannot be completely avoided or alleviated with mitigation. As a result, residual environmental effects are predicted. The combined suite of potential effects of the Project on wildlife habitat, movement and mortality risk constitute the potential residual effect for each indicator (Table 7.2.10-4). This approach was determined to be the most appropriate method of evaluating Project effects, since wildlife populations and individuals would potentially experience influences of all three effects pathways. Evaluation of the combined residual effect results in a realistic representation of the expected Project effects to the indicators for wildlife and wildlife habitat.

TABLE 7.2.10-4

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON WILDLIFE AND WILDLIFE HABITAT

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures[2]	Potential Residual Effect(s)
1. Wildlife Indicator – Grizzly Bear				
1.1 Change in habitat	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Temporary Facilities	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, wildlife disturbance and attraction of wildlife during construction, grizzly bear zone, mammal dens, species with special conservation status.	• Combined Project effects on grizzly bear resulting from habitat loss or alteration, changes in movement and increased mortality risk.
1.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, barriers to wildlife movement, wildlife disturbance and attraction of wildlife during construction, grizzly bear zone.	
1.3 Increased mortality risk		RSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, special access zone, grizzly bear zone, mammal dens, species with special conservation status.	
2. Wildlife Indicator – Woodland Caribou				
2.1 Change in habitat	Hargreaves to Darfield Temporary Facilities	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction; mountain caribou range, species with special conservation status.	• Combined Project effects on woodland caribou resulting from habitat loss or alteration, changes in movement and increased mortality risk.
2.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, barriers to wildlife movement, wildlife disturbance and attraction of wildlife during construction, mountain caribou range.	
2.3 Increased mortality risk		RSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, mountain caribou range, species with special conservation status.	
3. Wildlife Indicator – Moose				
3.1 Change in habitat	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Temporary Facilities Black Pines Pump Station Power line Kingsvale Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, wildlife disturbance and attraction of wildlife during construction, key wildlife and biodiversity zone, protective notations, moose winter range, mineral licks.	• Combined Project effects on moose resulting from habitat loss or alteration, changes in movement and increased mortality risk.
3.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, barriers to wildlife movement, wildlife disturbance and attraction of wildlife during construction, key wildlife and biodiversity zone, protective notations, moose winter range, mineral licks.	
3.3 Increased mortality risk		RSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, key wildlife and biodiversity zone, protective notations, moose winter range.	
4. Wildlife Indicator – Forest Furbearers				
4.1 Change in habitat	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Temporary Facilities Black Pines Pump Station Power line Kingsvale Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, mammal dens, species with special conservation status.	• Combined Project effects on forest furbearers resulting from habitat loss or alteration, changes in movement and increased mortality risk.
4.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, barriers to wildlife movement, wildlife disturbance and attraction of wildlife during construction, mammal dens.	
4.3 Increased mortality risk		RSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, mammal dens, species with special conservation status.	

TABLE 7.2.10-4 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures[2]	Potential Residual Effect(s)
5. Wildlife Indicator – Coastal Riparian Small Mammals				
5.1 Change in habitat	Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Sumas Terminal Westridge Marine Terminal	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, Pacific water shrew, mammal dens, species with special conservation status.	• Combined Project effects on coastal riparian small mammals resulting from habitat loss or alteration, changes in movement and increased mortality risk.
5.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, barriers to wildlife movement, wildlife disturbance and attraction of wildlife during construction, mammal dens.	
5.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, Pacific water shrew, mammal dens, species with special conservation status.	
6. Wildlife Indicator – Bats				
6.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, bats, species with special conservation status.	• Combined Project effects on bats resulting from habitat loss or alteration, changes in movement and increased mortality risk.
6.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, bats.	
6.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, bats, species with special conservation status.	
7. Wildlife Indicator – Grassland/Shrub-steppe Birds				
7.1 Change in habitat	Hargreaves to Darfield Black Pines to Hope Temporary Facilities Black Pines Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, sharp-tailed grouse range, sharp-tailed grouse lek, species with special conservation status.	• Combined Project effects on grassland/shrub-steppe birds resulting from habitat loss or alteration, changes in movement and increased mortality risk.
7.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, important bird area, sharp-tailed grouse range, sharp-tailed grouse lek.	
7.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, Important bird area sharp-tailed grouse range, sharp-tailed grouse lek, species with special conservation status.	
8. Wildlife Indicator – Mature/Old Forest Birds				
8.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor/owl nest species with special conservation status.	• Combined Project effects on mature/old forest birds resulting from habitat loss or alteration, changes in movement and increased mortality risk.
8.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, raptor/owl nest.	
8.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor/owl nest, species with special conservation status.	
9. Wildlife Indicator – Early Seral Forest Birds				
9.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	• Combined Project effects on early seral forest birds resulting from habitat loss or alteration, changes in movement and increased mortality risk.
9.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds.	
9.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	

TABLE 7.2.10-4 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures[2]	Potential Residual Effect(s)
10. Wildlife Indicator – Riparian and Wetland Birds				
10.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, trumpeter swan waterbodies/watercourses, species with special conservation status.	• Combined Project effects on riparian and wetland birds resulting from habitat loss or alteration, changes in movement and increased mortality risk.
10.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, important bird area, trumpeter swan waterbodies/watercourses.	
10.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, trumpeter swan waterbodies/watercourses, species with special conservation status.	
11. Wildlife Indicator – Wood Warblers				
11.1 Change in habitat	Edmonton to Hinton Temporary Facilities	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	• Combined Project effects on wood warblers resulting from habitat loss or alteration, changes in movement and increased mortality risk.
11.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds.	
11.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	
12. Wildlife Indicator – Short-eared Owl				
12.1 Change in habitat	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Black Pines Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor nest, species with special conservation status.	• Combined Project effects on short-eared owl resulting from habitat loss or alteration, changes in movement and increased mortality risk.
12.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, raptor nest.	
12.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor nest, species with special conservation status.	
13. Wildlife Indicator – Rusty Blackbird				
13.1 Change in habitat	Edmonton to Hinton Hargreaves to Darfield Black Pines to Hope Hope to Burnaby Temporary Facilities Black Pines Pump Station Power line Kingsvale Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	• Combined Project effects on rusty blackbird resulting from habitat loss or alteration, changes in movement and increased mortality risk.
13.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds.	
13.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	
14. Wildlife Indicator – Flammulated Owl				
14.1 Change in habitat	Black Pines to Hope Temporary Facilities Black Pines Pump Station Power line Kingsvale Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, raptor nest, species with special conservation status.	• Combined Project effects on flammulated owl resulting from habitat loss or alteration, changes in movement and increased mortality risk.
14.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, important bird area, raptor nest.	

TABLE 7.2.10-4 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures[2]	Potential Residual Effect(s)
14.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, raptor nest, species with special conservation status.	
15. Wildlife Indicator – Lewis's Woodpecker				
15.1 Change in habitat	Black Pines to Hope Temporary Facilities Black Pines Pump Station Power line Kingsvale Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, species with special conservation status.	• Combined Project effects on Lewis's woodpecker resulting from habitat loss or alteration, changes in movement and increased mortality risk.
15.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, important bird area.	
15.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, species with special conservation status.	
16. Wildlife Indicator – Williamson's Sapsucker				
16.1 Change in habitat	Black Pines to Hope Temporary Facilities Black Pines Pump Station Power line Kingsvale Pump Station Power line	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	• Combined Project effects on Williamson's sapsucker resulting from habitat loss or alteration, changes in movement and increased mortality risk.
16.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds.	
16.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	
17. Wildlife Indicator – Western Screech-owl				
17.1 Change in habitat	Black Pines to Hope Hope to Burnaby Burnaby to Westridge Temporary Facilities Black Pines Pump Station Power line Kingsvale Pump Station Power line Sumas Terminal Westridge Marine Terminal	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor nest, species with special conservation status.	• Combined Project effects on western screech-owl resulting from habitat loss or alteration, changes in movement and increased mortality risk.
17.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, raptor nest.	
17.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor nest, species with special conservation status.	
18. Wildlife Indicator – Great Blue Heron				
18.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, great blue heron nesting colony, species with special conservation status.	• Combined Project effects on great blue heron resulting from habitat loss or alteration, changes in movement and increased mortality risk.
18.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, important bird area, great blue heron nesting colony.	
18.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, important bird area, great blue heron nesting colony, species with special conservation status.	

TABLE 7.2.10-4 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures[2]	Potential Residual Effect(s)
19. Wildlife Indicator – Spotted Owl				
19.1 Change in habitat	Black Pines to Hope Temporary Facilities	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, Sowaqua spotted owl WHA, raptor nest, species with special conservation status.	• Combined Project effects on spotted owl resulting from habitat loss or alteration, changes in movement and increased mortality risk.
19.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, Sowaqua spotted owl WHA, raptor nest.	
19.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, Sowaqua spotted owl WHA, raptor nest, species with special conservation status.	
20. Wildlife Indicator – Bald Eagle				
20.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, sensitive raptor range, raptor nest, species with special conservation status.	• Combined Project effects on bald eagle resulting from habitat loss or alteration, changes in movement and increased mortality risk.
20.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, sensitive raptor range, raptor nest.	
20.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, sensitive raptor range, raptor nest, species with special conservation status.	
21. Wildlife Indicator – Common Nighthawk				
21.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	• Combined Project effects on common nighthawk resulting from habitat loss or alteration, changes in movement and increased mortality risk.
21.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds.	
21.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	
22. Wildlife Indicator – Northern Goshawk *laingi* ssp.				
22.1 Change in habitat	Hope to Burnaby Burnaby to Westridge Temporary Facilities Sumas Terminal Westridge Marine Terminal	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor/owl nest, species with special conservation status.	• Combined Project effects on northern goshawk resulting from habitat loss or alteration, changes in movement and increased mortality risk.
22.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds, raptor/owl nest.	
22.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, raptor nest, species with special conservation status.	
23. Wildlife Indicator – Olive-sided Flycatcher				
23.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	• Combined Project effects on olive-sided flycatcher resulting from habitat loss or alteration, changes in movement and increased mortality risk.
23.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, migratory birds.	
23.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, migratory birds, species with special conservation status.	

TABLE 7.2.10-4 Cont'd

Potential Effect	Project Component(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures[2]	Potential Residual Effect(s)
24. Wildlife Indicator – Pond-dwelling Amphibians				
24.1 Change in habitat	All	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, amphibian breeding pond, species with special conservation status.	• Combined Project effects on pond-dwelling amphibians resulting from habitat loss or alteration, changes in movement and increased mortality risk.
24.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, amphibian breeding pond.	
24.3 Increased mortality risk		RSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, amphibian breeding pond, species with special conservation status.	
25. Wildlife Indicator – Stream-dwelling Amphibians				
25.1 Change in habitat	Black Pines to Hope Hope to Burnaby Temporary Facilities Sumas Terminal	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, stream dwelling amphibians, species with special conservation status.	• Combined Project effects on stream-dwelling amphibians resulting from habitat loss or alteration, changes in movement and increased mortality risk.
25.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, stream dwelling amphibians.	
25.3 Increased mortality risk		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, stream dwelling amphibians, species with special conservation status.	
26. Wildlife Indicator – Arid Habitat Snakes				
26.1 Change in habitat	Black Pines to Hope Temporary Facilities	LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, disturbance and attraction of wildlife during construction, reptiles, species with special conservation status.	• Combined Project effects on arid habitat snakes resulting from habitat loss or alteration, changes in movement and increased mortality risk.
26.2 Change in movement		LSA	• Refer to Table 7.2.10-3: habitat loss/alteration, access and line-of-sight management, wildlife disturbance and attraction of wildlife during construction, reptiles.	
26.3 Increased mortality risk		RSA	• Refer to Table 7.2.10-3: habitat loss/alteration, disturbance and attraction of wildlife during construction, reptiles, species with special conservation status.	

Notes: 1 Refer to Section 7.2.10.2 for an explanation of spatial boundaries relevant to each indicator.
2 Refer to Table 7.2.10-3 for complete recommendations and mitigation.

7.2.10.8 Significance Evaluation Approach for Wildlife and Wildlife Habitat

All assessment criteria were considered for each residual effect. Where appropriate, the key or most influential assessment criteria used to determine the significance of each residual effect are noted (*e.g.,* magnitude, reversibility, probability). The significance determinations incorporate professional judgment, which allows integration of all of the effects criteria ratings to provide relevant significance conclusions that are sensitive to context and facilitate decision-making (Lawrence 2007).

Quantitative metrics (*e.g.,* change in area of suitable habitat) and accepted biological thresholds or standards (*e.g.,* road density for grizzly bear) are incorporated into the characterization of magnitude for each residual effect, where available. The sensitivity of the indicator (*e.g.,* indicated by conservation status, population trend and sensitivity to disturbance), where relevant, was considered in the determination of magnitude when biological thresholds or standards were not available, such as in the assessment of movement and mortality risk for most wildlife indicators. In the absence of biological thresholds or standards, the magnitude evaluation also considered relevant land use planning objectives and strategies, and previous environmental assessments reviewed and approved under provincial and federal environmental regulatory processes, where appropriate. These sources provide useful information on social values and risk tolerance, which are an essential component of significance determination.

7.2.10.9 Significance Evaluation of Potential Residual Effects on Mammal Indicators

The mammal indicators for the Project include grizzly bear, woodland caribou, moose, forest furbearers, coastal riparian small mammals and bats (Table 7.2.10-1). Pipeline and facility construction and operations activities have the potential to affect mammals by causing changes in habitat, movement and mortality risk. Detailed species accounts (including species lists for the community indicators) are described in the Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C.

Relevant regulatory guidelines, information identified during Aboriginal participation and ecological context were considered in the characterization of potential residual effects for the mammal indicators. A summary of regulatory guidelines is provided in Section 7.2.10.4.

The compilation of ATK, including the collection of TEK through Aboriginal field participation and engagement provided valuable information on mammals along the proposed pipeline corridor, and identified concerns and potential effects of the Project. Consultation and engagement details regarding wildlife, ATK and TEK are provided in the Wildlife Technical Report of Volume 5C, and this information is included and considered throughout the effects assessment on mammal indicators.

Information on the ecological context for each mammal indicator (*e.g.*, species status, population trends, known threats, best management practices and conservation strategies) is provided in Table 7.2.10-5. The purpose of providing ecological context for each indicator is to provide an indication of the resilience of each indicator to disturbance effects.

TABLE 7.2.10-5

ECOLOGICAL CONTEXT SUMMARY FOR MAMMAL INDICATORS

Mammal Indicator	Ecological Context
Grizzly Bear	• Grizzly bears are Blue-listed in BC and have a Conservation Framework Priority rating of 2 (BC CDC 2013). Grizzly bears are designated as at Risk in Alberta and are listed as Threatened under the Alberta *Wildlife Act* and *Wildlife Regulation* (AESRD 2012a, ASRD 2011b). The western population of grizzly bears is federally listed as a species of Special Concern under COSEWIC due to extensive range and population reductions influenced by habitat development and fragmentation, and human-related conflicts and mortality (Ross 2002). Grizzly bear are also listed under Schedule 3 of *SARA* (Environment Canada 2013c). • The Project intersects two Bear Management Areas (also referred to as Grizzly Bear Population Units [GBPUs]) in Alberta: Grande Cache and Yellowhead (AESRD 2013d, ASRD 2008). The Project intersects three viable GBPUs in BC, including the Columbia-Shuswap, Wells Gray and Robson, and one threatened GBPU, the North Cascades (BC MFLNRO 2012b). The total population within the two GBPUs in Alberta is estimated at 395 individuals (ASRD ACA 2010) and the total population within the three viable GBPUs in BC is estimated at 1,197 individuals (BC MFLNRO 2012b). The BC MOE has identified objectives for the viable GBPUs in BC, including maintaining current population abundance and distribution, and providing sustainable harvest and viewing opportunities where appropriate (BC MFLNRO 2012b). The North Cascades GBPU has an estimated population of six individuals (BC MFLNRO 2012b). The management objective for threatened GBPUs in BC is population recovery to prevent range contraction and ensure long-term population viability (BC MFLNRO 2012b). • Cumulative effects of human development are identified as the greatest threat to grizzly bears (ASRD ACA 2010, BC MOE 2012c). • Grizzly bear is managed as a game animal in most viable GBPUs in BC. Hunting seasons are provided for Aboriginal communities, resident and, in some cases, non-resident hunters. Hunting seasons are closed in threatened population units and some viable GBPUs where known grizzly bear mortality has met or exceeded allowable limits established through the BC MOE's Grizzly Bear Harvest Management Procedure. The viable GBPUs crossed by the Project are open for hunting (BC MOE 2012c). In Alberta the spring grizzly bear hunt was suspended in 2006 to allow for a better population assessment. The hunting suspension continued through 2012 and 2013 (Government of Alberta 2012). • Grizzly bear mortality is primarily related to direct human causes (ASRD 2008, Austin and Wrenshall 2004, Hamilton *et al.* 2004, Kansas 2002, McLellan 1990, Ross 2002). Bear-human conflicts can result in mortality as bears may be destroyed ("animal control") or relocated. Hunting and poaching, and collisions with vehicle/rail traffic are also key factors in grizzly bear mortality (BC MOE 2012c, Ross 2002). Within the viable GBPUs crossed by the Project, hunting is the primary cause of mortality for grizzly bears (BC MOE 2012c). • Disturbance from anthropogenic noise created by roads has been found to have a negative effect on habitat use by grizzly bears. Work by Mace *et al.* (1996) found that noise from road activity of more than 10 vehicles per day (*e.g.,* primary and secondary roads) negatively affects grizzly habitat occupancy up to 500 m into the forest from the disturbance. • Roads are demonstrated to affect grizzly bear habitat effectiveness, fragment habitat (*e.g.*, create barriers/filters to movement; alienate bears from suitable habitat) and increase mortality risk (Hamilton pers. comm.). at the regional scale (*i.e.*, GBPU), open road density higher than 0.6 km/km^2 is known to affect grizzly bear habitat use, and these effects are magnified when road density increases over approximately 1.0 km/km^2 (ASRD 2008, BC MOE 2012c, BC MWLAP 2004b). Motorized access density of 0.6 km/km^2 is adopted in this assessment as a biological threshold for a high magnitude effect. • The Robson Valley LRMP recommends maintaining or enhancing habitat and/or increase numbers, genetic variability and distribution of grizzly bears (BC ILMB 1999).

TABLE 7.2.10-5 Cont'd

Mammal Indicator	Ecological Context
Grizzly Bear (cont'd)	• Valemount to Blue River and Eight Peaks Winter Recreation SRMPs recommend incorporating measures into the design of winter activities and developments that minimize impacts on grizzly bear habitat and denning sites and bear human conflicts (BC ILMB 2005, BC MSRM 2003). • The Alberta Grizzly Bear Recovery Plan 2008-2013 has been implemented within Alberta in an attempt to reduce human-caused mortality of grizzly bears, improve knowledge about the population within Alberta, reduce the number of human-bear conflicts, improve and deliver education programs to the public (*i.e.*, Bear Smart), maintain quality habitat, and improve inter-jurisdictional cooperation (ASRD 2008). A hunting moratorium was also put in place in 2006 and additional conservation initiatives include increasing the maximum poaching fine, delineating Bear Management Areas (comparable to Grizzly Bear Population Units), DNA population censuses in certain Bear Management Areas, financial support for government staff biologists, implementation of the Bear Smart Community Program, and aversive conditioning of grizzly bears in high risk areas (ASRD 2008). The North Cascades Grizzly Bear Recovery Team was initiated to restore this population to viable status. Seven objectives of the Recovery Plan were established including: providing habitat of sufficient quality and quantity; preventing population fragmentation and maintain genetic diversity; increasing the total number of grizzly bears in the North Cascades; minimizing the potential for human/bear conflict; minimizing human-caused mortality of grizzly bears; increasing scientific and public knowledge and support for grizzly bear recovery; and facilitating interagency cooperation and management (North Cascades Grizzly Bear Recovery Team 2004). • Table 7.2.10-7 provides a summary of the predicted change in grizzly bear habitat as a result of the Project.
Woodland Caribou	• The Wells Gray and Groundhog caribou herds are mountain ecotype woodland caribou, within the Southern Mountain Designatable Unit (DU9). Mountain ecotype caribou are Red-listed, have a Conservation Framework Priority rating of 2 (BC CDC 2013), and are designated as Threatened under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c). • The proposed pipeline corridor traverses the Wells Gray caribou range for approximately 30.7 km, of which 22 km (71.7%) are parallel to existing linear disturbance and 8.7 km (28.3%) is new cut. The proposed pipeline corridor traverses the Groundhog caribou range for approximately 10.3 km, of which 9.1 km (88.3%) are contiguous with existing linear disturbance and 1.2 km (11.7%) is new cut. Table 7.2.10-7 provides a summary of the predicted change in disturbance within caribou ranges and the approved UWR encountered by the proposed pipeline corridor. • The proposed pipeline corridor intersects one approved Ungulate Winter Range (UWR) for caribou in the Wells Gray caribou range: u-3-004 (mountain caribou). Within u-3-004, the corridor is located in a modified harvest zone. No UWRs for caribou are encountered in the Groundhog caribou range. • The Wells Gray caribou herd was estimated at 422 individuals in 2006, which is an increase from the 2004 of 307 individuals (Hatter 2006, Seip *et al.* 2005) suggesting that the recovery probability for this herd remains high. The Groundhog caribou herd was estimated at 23 individuals in 2008, 30 individuals in 2006, 23 individuals in 2004 and 43 individuals in 1995 (Furk 2008, Hatter 2006, Seip *et al.* 2005). The herd is small and extremely isolated from other mountain caribou populations and a population viability analysis estimated a high probability of extinction of the Groundhog Caribou Herd within 30 years (Wittmer *et al.* 2010). • Mountain ecotype caribou are generally found at elevations of 1,500-2,100 m; however, this can vary with year, season, local population and individual (BC MWLAP 2004b). Seasonally, mountain ecotype caribou generally exhibit weak horizontal range shifts, but strong elevational shifts (Hatter *et al.* 2009) from valley bottoms and lower slopes in early winter, to alpine and sub-alpine habitats in late winter and low-elevation snow-free areas in spring (BC MWLAP 2004b, Mountain Caribou Technical Advisory Committee [MCTAC] 2002). Sub-alpine forests and alpine areas are used in summer. Parturient females move to exposed locations in high elevation alpine and sub-alpine areas to calve in spring and early summer. These sites offer refuge from most predators, but are often food-limited (BC MWLAP 2004b, MCTAC 2002). • The Robson Valley LRMP recommends protecting high elevation caribou winter range habitat and improving understanding of the behaviour and biology of caribou populations and the effects of resource development on caribou habitat (BC ILMB 1999). • The Kamloops LRMP recommends maintaining opportunities for mineral exploration and development while ensuring that these activities will be undertaken with sensitivity to caribou habitat (BC ILMB 1995). • Within the Kamloops LRMP, the North Thompson Caribou Special Resource Management Zone is divided into planning cells and corridors and outlines management goals which include to maintain the quantity of habitat required to support viable populations within the plan area, and to maintain connectivity with adjoining areas, and to maintain or improve the effectiveness and quality of suitable mountain caribou habitats within core winter planning cells. The proposed pipeline corridor traverses movement corridor areas which have objectives including facilitating caribou movement within and between seasonal habitats and between populations, maintaining the suitable habitat necessary for caribou movement within corridors, by maintaining a minimum 33% of the capable habitat area as suitable habitat to provide security without impeding caribou movement, maintaining the functionality of confirmed trails over time, and employing harvest and silviculture activities that retain caribou habitat attributes, or that are intended to accelerate the recovery of caribou habitat suitability. Other objectives that may be relevant to the Project include managing and coordinating access in and adjacent to core planning cells and corridors so that habitat effectiveness is not diminished, and minimizing the amount and density of roads within caribou movement corridors (Kamloops LRMP Mountain Caribou Subcommittee 2006).

TABLE 7.2.10-5 Cont'd

Mammal Indicator	Ecological Context
Woodland Caribou (cont'd)	• The BC government announced the Mountain Caribou Recovery Implementation Plan (MCRIP) in 2007, with the goal to stop the decline of mountain caribou populations by 2014 and recover the population to pre-1995 levels (2,500 animals) within 20 years (*i.e.*, 2027). Recovery objectives include: - protecting all high suitability early and late winter mountain caribou habitat from logging and road building (*e.g.*, increasing fully protected high-suitability winter habitat from 65% to 95%) to address caribou mortality associated with habitat loss and fragmentation; - managing winter backcountry recreational activities (*e.g.*, snowmobiling, heli-skiing, cat-skiing) through education, closures and moratoriums; - managing predator (wolf and cougar) populations; - managing primary prey populations (deer, moose) to re-balance the predator-prey system; - augmenting critically endangered herds through transplanting animals; and – monitoring and adaptive management (BC ILMB 2007). • The BC MOE is responsible for implementing the MCRIP and convened the Mountain Caribou Science Team, which identified several recommendations to achieve the MCRIP objectives and timelines, including: predator population control; augmentation of the South Purcell herd and all herds with fewer than 20 animals; and reduction in moose densities in mountain caribou range through management of hunting seasons and cow moose harvest allowances. The Science Team also recommended: minimizing forestry-related activities in core habitat; enforcement of recreation restrictions; and complete census of mountain caribou herds every 3 years (BC MOE 2009). • The Environmental Protection and Management Guide (BC OGC 2013) includes recommended guidelines for operations in caribou range in BC, including measures related to road construction, snow berms, speed limits, line-of-sight management, pipeline construction, reclamation and restoration, and stewardship. The intent of the recommendations is to limit activities within caribou UWRs that affect lichen forage availability, predator mobility and hunting efficiency, forage for other ungulate species, and fragmentation of habitat. • Consultation with the local BC MFLNRO wildlife biologist identified restriction of construction timing to late winter, spring, or summer, and early seral vegetation and ungulate (moose) management as key management objectives in the Project area (Surgenor pers. comm.). • Table 7.2.10-7 provides a summary of the predicted change in caribou habitat as a result of the Project.
Moose	• Moose are not listed provincially or federally (ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c), and are considered to be of lowest (6) conservation priority in BC (BC CDC 2013). • The most recent (2011) estimate for BC's moose population is 145,000 to 235,000 (BC MFLNRO 2013c,d). BC MFLNRO surveys conducted in the Thompson and Okanagan Region during winter 2012/2013 indicate moderate moose densities and low bull to cow ratios in the Monte Hills south of Kamloops. In parts of the North Thompson, an approximate 60% decline in moose densities was documented and due to limited hunting in the areas it is suggested that wolf predation may be a factor. In response to these results, the BC MFLNRO is continuing regular engagement with stakeholders and First Nations supporting a radio-collaring initiative in the Thompson and Okanagan region to examine moose survival and habitat use (BC MFLNRO 2013c). • There is no provincial estimate for moose in Alberta, however, the species in common throughout most eco-regions, except for the prairie and parkland (Pattie and Fisher 1999). • Limiting factors for moose populations include food availability, weather, hunting, parasites/disease and predation (Gasaway *et al.* 1992, Keystone Wildlife Research Ltd. 2006). Predation, availability of food, climate, parasites and disease are the most important natural factors potentially limiting moose populations. Moose populations are considered more sensitive to overharvest and other sources of mortality than to habitat loss and fragmentation (Antoniuk *et al.* 2009). Hunting is often the primary limiting factor of moose populations in areas accessible to humans (Dussault *et al.* 2005). Predation by wolves is an important factor for moose mortality. Wolves are known to travel on roads during winter, but have been shown to avoid them in areas with high levels of human activity, likely due to increased mortality risk (Kunkel and Pletscher 2000). This may explain why moose predation by wolves in the Flathead River area in BC was lower in areas of high road densities (Kunkel and Pletscher 2000). • Linear features such as secondary roads and seismic lines are not considered an impediment to moose movement (Collister *et al.* 2003). Reduced use or avoidance of linear features such as roads, trails and seismic lines by moose has been documented in some regions (Collister *et al.* 2003, Ferguson and Keith 1985, Rolley and Keith 1980). However, moose have been shown to exhibit heavy use of forestry roads and cutblocks during winter in other regions, presumably due to better forage availability and lower wolf densities (Kunkel and Pletscher 2000, Serrouya and D'Eon 2002). • Levels of human activity (*e.g.*, noise, traffic) affect moose response to anthropogenic disturbance (Collister *et al.* 2003). Wasser *et al.* (2011) reported moose avoided linear features with no or unknown levels of human use and areas near primary roads; however, avoidance effects were not apparent for moose beyond several hundred metres of exploration roads. Sensory disturbance of moose can result in displacement to less suitable habitats. Although sensitive to human disturbance, moose will habituate to non-threatening and repetitive activities (Wiacek *et al.* 2002). • Stand-initiating disturbances such as fire and forest harvest can create high quality forage sources for moose, since the canopy is opened and forage production is increased. Optimal successional stages for moose forage in burned areas usually occur 10 to 30 years following fire (Nietfeld *et al.* 1985, Peek 2007) and 10 to 15 years following forest harvest (Collister *et al.* 2003). Moose may use recently burned areas less frequently than remnant forests, and browse shrubby vegetation within young burns near forest edges (*i.e.*, less than 100 m from forest edges) (Peek 2007). In the Southern Interior region of BC, moose require a mix of forest age classes that provides browse as well as mature forest with high canopy closure (*i.e.*, snow interception cover and thermal cover) (Wall *et al.* 2011).

TABLE 7.2.10-5 Cont'd

Mammal Indicator	Ecological Context
Moose (cont'd)	• The Robson Valley LRMP recommends maintaining or enhancing populations and habitat for moose and the Kamloops LRMP recommends maintaining thermal and visual cover for moose, and enhancing browse production (BC ILMB 1995, 1999). • The Coal Branch Sub-Regional Integrated Resource Plan along the Edmonton to Hinton Segment recommends ensuring that populations of moose are maintained or increased (Alberta Forestry, Lands and Wildlife [AFLW] 1990). • The proposed pipeline corridor traverses areas that the Kamloops LRMP has identified as areas of moose winter range. Objectives for these areas include: maintaining thermal and visual cover for moose, and enhancing browse production; and maintaining suitable forest cover attributes with respect to thermal cover and forage production (BC Ministry of Agriculture and Lands 2006). Within these areas, it is recommended that construction not occur from December 1 to March 15 (Surgenor pers. comm.). • Table 7.2.10-7 provides a summary of the predicted change in moose habitat as a result of the Project.
Forest furbearers	• The assessment of forest furbearers focused on marten, fisher and wolverine, as these representative species are considered environmental indicators (*i.e.*, sensitive to change), have human (subsistence, cultural) and conservation importance, and have potential to interact with the Project. • Marten is not a species of conservation concern provincially or federally (ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c). Marten populations are considered to be Apparently Secure to Secure in BC and Secure in Alberta (ASRD 2011b, BC Conservation Framework 2013) and are Yellow-listed in BC (BC CDC 2013). Fisher and wolverine are Blue-listed species in BC and have Conservation Framework Priority ratings of 2 (BC CDC 2013). Fisher are designated as Sensitive in Alberta (ASRD 2011b), and have no federal designation under COSEWIC or *SARA*. Wolverine are designated as May Be at Risk in Alberta (ASRD 2011b), and are federally listed as a species of Special Concern by COSEWIC given a low intrinsic rate of population growth coupled with trapping and habitat loss and fragmentation (COSEWIC 2003a). Wolverine are also listed under Schedule 3 of *SARA* (Environment Canada 2013c). • Population density estimates for marten across North America range from 0.4 to 2.4 animals/km^2 (Hatler *et al.* 2003a). Population density estimates for the Project area are not known; however, in the Selkirk Mountains of southeastern BC, marten density is estimated to be 0.33 animals/km^2 (Mowat and Paetkau 2002). Marten abundance may experience dramatic annual fluctuations due to changes in prey availability (Hatler *et al.* 2003a). • Fishers occur in low densities throughout much of their range in BC, which has been found to vary between ecological regions of BC based on habitat quality (Weir *et al.* 2011). For example, a study in the Williston Sub-Boreal Spruce BGC of BC estimated an average density of 8.8 fishers/1,000 km^2 (Weir and Corbould 2006), whereas a study by Weir *et al.* (2011) using the same methods in the boreal mixed-wood forests found almost double the density (16.3 fishers/1,000 km^2). • The population estimate for fishers in BC is estimated at 3,800 individuals (BC CDC 2013). Fisher population trends in BC are difficult to determine due to the lack of inventory information. Primary threats to fisher populations in BC are likely anthropogenic and occur through changes to habitats from development of forested lands (*i.e.*, logging, hydro-electric development, and land clearing) and changes in survival rates caused by trapping (BC MWLAP 2004b, Weir 2003). Fishers are particularly sensitive to intensive forest harvesting practices that occur quickly and cover large areas (*e.g.*, mountain pine beetle salvage harvests) (Weir and Almuedo 2010). Recent research in north-central BC estimated that harvesting 250 ha of forest in a 50 km^2 area (*i.e.*, a female home range) within a 12 year span reduces the likelihood of the area supporting a resident fisher by 50% (Weir and Almuedo 2010). Based on rates of habitat loss within areas known to support fisher, it is estimated that populations are declining annually by 20-30%; however, long-term population declines based on habitat loss are estimated at 25-50% (BC CDC 2013). • Wolverine occur at low densities throughout most of BC (BC MWLAP 2004b) and are expected to be most abundant in the interior mountain regions (Lofroth and Krebs 2007). Wolverines are more likely to occur in topographically rugged terrain and areas where industrial activity and habitat alteration is low (Fisher *et al.* 2013). • Marten, fisher and wolverine are managed as a fur-bearing species in Alberta and BC. Fisher and wolverine are categorized as a Class 2 species for fur harvest management in BC, which identifies them as sensitive to harvest (Hatler *et al.* 2003b). The harvest season for fisher was closed province wide due to concerns about the sustainability of the population from 1990 to 1992 (BC CDC 2013), however, harvest of fishers through incidental kills remained basically unchanged (Weir and Courbold 2000 in BC CDC 2013). Based on modelling of wolverine populations and harvest records from 1985 to 2004, harvest of wolverine at the provincial scale was sustainable (Lofroth and Ott 2007). • In Alberta, the fisher population status is unknown and distribution is uncertain (AESRD 2013d). Provincial fur production records in Alberta indicate the number of fisher harvested over four seasons from 2007 to 2011 ranged from 1,143 to 1,344 over the 2007/08 to 2010/11 seasons, with a large increase to 2,095 during the 2011/12 season (Government of Alberta 2013). • The wolverine is not common in Alberta and is found in the northern half of the province and along the Rocky Mountains (Petersen 1997) with wildlife management units bordering Jasper National Park reporting some of the highest harvest densities in Alberta (Alberta Conservation Association 2011). The number of wolverine harvested over five seasons from 2007 to 2012 have been slowly increasing from 26 in 2007-2008 to 41 in 2011-2012, with the highest number (54) produced in 2010-2011 (Government of Alberta 2013). • Limited distribution, low reproductive rates and large home ranges suggest fisher populations have a low resiliency or ability to recover from a reduction in numbers (BC MWLAP 2004b). Wolverine populations have low resiliency to population perturbation (*e.g.*, fur trapping) because of their low densities, large home range sizes, and relatively low reproductive rate (BC MWLAP 2004b). • Marten may move to lower elevations in winter when snowpack is high in mountainous coastal areas (Banfield 1974, Buskirk 1983, Steventon and Major 1982). Commonly reported refuge sites include ground burrows, rock piles and crevices, downed logs, stumps, snags, brush or slash piles and squirrel middens (Bull and Heater 2000, Buskirk 1984, Ruggiero *et al.* 1998, Steventon and Major 1982).

TABLE 7.2.10-5 Cont'd

Mammal Indicator	Ecological Context
Forest furbearers (cont'd)	• Marten and fisher habitat typically includes a mosaic of forest communities and seral stages, often with a relatively high proportion of mid- to late-seral forests (Bowman and Robitaille 1997, Buskirk and Powell 1994, Raley *et al.* 2012), including those that are deciduous-dominated (Poole *et al.* 2004). Fishers have been described as "area sensitive", meaning the frequency of fisher occurrence increases with increased size of late-successional forest stands, and they are less prevalent in forested landscapes with high levels of fragmentation (Powell and Zielinski 1994). Marten are often referred to as old-growth dependent and in northern boreal forests are closely associated with late successional coniferous stands, especially those dominated by spruce and fir, which have a complex coarse woody debris structure (Buskirk and Powell 1994, Slough 1989). • Coarse woody debris is an important ecological element for marten and fisher. Marten use coarse woody debris for thermal insulation and access to subnivean prey in winter, denning in spring, and for hunting and protection from predators all year (Buskirk and Powell 1994, Buskirk and Ruggiero 1994, Sherburne and Bissonette 1994, Taylor and Buskirk 1994, Thompson and Colgan 1994, Thompson and Harestad 1994). Complex forest structure provides security cover, microclimates for thermoregulation and potentially abundant prey for fisher (Raley *et. al.* 2012). • Open areas (*e.g.*, non-forested areas, large forest openings, open hardwood forests, recent clear-cuts, grasslands and areas above the timberline) and young seral stage forests are low-value habitat for marten and fisher and are typically avoided or used infrequently (Buskirk and Ruggiero 1994, Cheveau *et al.* 2013, Poole *et al.* 2004, Powell and Zielinski 1994, Soutière 1979, Spencer *et al.* 1983). However, fishers may occasionally use managed forests with little overhead cover and recently clear-cut areas, particularly in summer when shrubs and saplings may provide sufficient cover. These areas are generally avoided in winter when there is little cover and higher snow depths (Powell and Zielinski 1994). Marten will cross forestry roads and small clearings (Buskirk 1984, Buskirk and Ruggerio 1994) and in some situations, marten have been observed crossing relatively large non-forested openings (*e.g.*, 300 m); however, these movements were attributed to home range shifts or dispersion, rather than being typical of movements within a home range (Buskirk 1984). • Recommendations in the Identified Wildlife Species Account and status report for fisher include maintaining sufficient suitable habitat (*i.e.*, 30-45% mature and old forest with shrub cover, coniferous canopy cover, sub-hygric or wetter moisture regime, patches of large declining trees [especially black cottonwood] and greater than average amounts of coarse woody debris) and maximizing landscape connectivity using corridors of mature and old seral forests centered on stream systems (BC MWLAP 2004b, Weir 2003). Maintaining a 100 m riparian area buffer at ecologically relevant places along streams to help maintain landscape connectivity is also recommended for fisher (BC MWLAP 2004b). • The Identified Wildlife Species Account for wolverine suggests that the cumulative impacts of trapping, habitat alteration, forest harvesting, and forest access on wolverine populations is not well understood (Banci 1994 in BC MWLAP 2004b). The large-scale conversion of mature and old forest structural stages into early structural stage habitats is a major threat to wolverine habitat (BC MWLAP 2004b). Recommendations include creating refugia, planning development to occur on one side of a watershed at a time, minimizing road access, maintaining seasonal foraging areas, maintaining and minimizing disturbance to suitable denning sites, and retaining suitable movement and dispersal corridors (BC MWLAP 2004b). • Provincial recovery actions identified for fisher and wolverine under the BC Conservation Framework include monitoring population trends, compiling a status report, planning, reviewing resource use, habitat protection and restoration, and private land stewardship (BC CDC 2013). There are currently no federal recovery plans for marten, fisher or wolverine (Environment Canada 2013c), and no provincial recovery plans for these furbearers in Alberta (Government of Alberta 2013a). • The Coal Branch Sub-Regional Integrated Resource Plan along the Edmonton to Hinton Segment recommends maintaining viable, abundant and diverse populations of furbearers, and maintaining a mosaic of habitat types (AFLW 1990). • Table 7.2.10-7 provides a summary of the predicted change in marten and fisher habitat as a result of the Project.
Coastal riparian small mammals	• There are several small mammal species with conservation status designations of concern, which have potential to occur within the Lower Mainland region of BC, overlapping the Wildlife LSA (AESRD 2012a, ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - Pacific water shrew (Endangered under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 1); - mountain beaver (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 1 [*rainier* spp.] and 2 [*rufa* spp.]); - Olympic shrew (Red-listed in BC; Conservation Framework Priority 1); - Townsend's mole (Endangered under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 1); and - Trowbridge's shrew (Blue-listed in BC; Conservation Framework Priority 2). • The coastal riparian small mammal indicator is defined to include Pacific water shrew and mountain beaver specifically, but also addresses the broader community of small mammals that rely, at least for some life requisites, on riparian habitats in the coastal region of BC. • Population estimates are not available for Pacific water shrew but it is considered a rare species and important habitat continues to be lost to urban and agricultural developments and forestry (BC MWLAP 2004b, COSEWIC 2006d). They are restricted to the southwest corner of BC and can generally be found within 50 m of slow-moving streams and marshes (McComb and Anthony 1993, Whitaker and Maser 1976, Zuleta and Galindo-Leal 1994), and have been considered by some as a wetland-dependant species (Gomez and Anthony 1998). • Population estimates of mountain beaver are not well known because search effort had not been intensive with its range, but is likely > 10,000 mature animals in BC. A minimum of 1,500 mountain beaver dens have been identified in BC (COSEWIC 2012d). Primary threats to mountain beavers include climate change, habitat loss due to urban and agricultural development and habitat loss and soil compaction from forestry activities (COSEWIC 2012d).

TABLE 7.2.10-5 Cont'd

Mammal Indicator	Ecological Context
Coastal riparian small mammals (cont'd)	• The proposed pipeline corridor crosses proposed critical habitat for Pacific water shrew (Environment Canada 2013d). A proposed recovery strategy for Pacific water shrew has been completed, but has not yet been posted on the Species at Risk Public Registry for public consultation. The proposed pipeline corridor also crosses early candidate critical habitat for Townsend's mole, for which a recovery strategy has not yet been completed (Environment Canada 2013d). The Wildlife Technical Report in Volume 5C provides additional information regarding proposed and candidate critical habitats. • Pacific water shrew has been reported in the Surrey Bend Regional Park (BC CDC 2013). The Surrey Bend Management Plan guiding principal is to protect and enhance sensitive ecosystems and important habitats for wildlife and vegetation, including bog, marsh, and riparian forest areas (Metro Vancouver and City of Surrey 2010). • The goal of the *Recovery strategy for the Pacific water shrew* (*Sorex bendirii*) *in BC* is to maintain the current population of Pacific water shrew with no further loss of local populations and restore this species back to its historical range where suitable habitat still exists or can be restored (Pacific Water Shrew Recovery Team 2009). This goal will be achieved through seven objectives including: protecting all known extant locations; restoring historical and important potential habitat; preventing habitat fragmentation and maintaining connectivity; preventing inadvertent loss of unknown populations through surveys, modeling, and mapping; addressing immediate threats and mitigating direct mortality; evaluating implemented protective measures and recovery activities; and increasing our understanding of important habitat, life history, population dynamics, habitat use, and threats to the population. • The goal of the *Management plan for the Mountain Beaver (*Aplodontia rufa*) in BC* is to maintain the current distribution of all subpopulations in BC and maintain or improving the current abundance of each subpopulation (BC MOE 2013g). This goal will be achieved through three objectives including: protecting and/or maintaining habitat within the occupied range; assessing and mitigating the impacts of ongoing threats, particularly timber harvest/silviculture and residential urban development and road building; and addressing identified key knowledge gaps including population abundance, location of suitable habitat, and population viability. • A 100 m buffer from suitable Pacific water shrew habitat is recommended (Craig *et al.* 2010). The *Develop with Care Guidelines* (BC MOE 2012a) recommend a minimum 50 m buffer around mountain beaver colonies, tunnels and burrows. The *BC Coast Region Species and Ecosystems of Concern* suggest that a minimum, permanent 500 m buffer be established from mountain beaver burrows with structurally intact habitat features, and 100 m around water features (Zivet and Lindgren 2012). • Table 7.2.10-7 provides a summary of the predicted change in Pacific water shrew habitat capability and mountain beaver habitat suitability as a result of the Project.
Bats	• Bat species with potential to occur within the wildlife LSA include 13 species including the following species of conservation concern (AESRD 2012a, ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - Townsend's big-eared bat (Blue-listed in BC; Conservation Framework Priority 2); - spotted bat (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - silver-haired bat (Yellow-listed in BC; Conservation Framework Priority 2; Sensitive in Alberta); - western small-footed myotis (Blue-listed in BC; Conservation Framework Priority 3; Sensitive in Alberta; Special Concern by Alberta's Endangered Species Conservation Committee [ESCC]); - Keen's myotis (Blue-listed in BC, Conservation Framework Priority 1); - little brown myotis (Endangered by COSEWIC; Yellow-listed in BC; Secure in Alberta); - northern myotis (Endangered by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2; May Be at Risk in Alberta); and - fringed myotis (Blue-listed in BC; Conservation Framework Priority 3). • There are currently no federal or provincial recovery strategies or conservation plans for the bat species potentially occurring along the proposed pipeline corridor. • There is limited information available regarding bat habitat, movement, population status, trends and threats. Known threats include wind energy facilities and white-nose syndrome (BC CDC 2013). The nearest bat population infected with white-nose syndrome in Canada is in northwestern Ontario. • Forest edges are often associated with elevated bat foraging activity, likely because they provide openings required by bats, provide movement corridors, or accumulate insects (Jantzen 2012, Morris *et al.* 2010). Clearings, meadows, wetlands and other openings provide foraging habitat for bat species that forage for insects in the open (*e.g.*, little brown bats). Clutter-adapted species (*e.g.*, northern myotis) forage in the understory of forests (Morris *et al.* 2010, Patriquin and Barclay 2003). • Tree-cavities are extensively used for roosting by several bat species, and may be used as hibernacula in warmer areas of the province (Kalcounis-Ruppell *et al.* 2005, Nagorsen and Brigham 1993). Suitable tree-cavity roosting habitat is most often associated with old mixed or deciduous forests containing large-diameter decaying trees, which have cavities, crevices or sloughing bark where bats can hide (Kalcounis-Ruppell *et al.* 2005). • Refer to Table 7.2.10-7 for a summary of the predicted change in tree-roosting bat habitat as a result of the Project. • Caves and mines as well as tall rock faces with deep fissures are likely the primary hibernation habitat for bats, which may also be used as roosting habitat during the summer (Lausen and Barclay 2006, Nagorsen and Brigham 1993). There are no caves or mines along the proposed pipeline corridor (Wildlife Technical Report of Volume 5C).

Construction and operations of the Project will create new forest clearing, increase the existing corridor width where existing linear disturbances are paralleled, potentially remove site-specific habitat features (*e.g.*, forage/browse, security/thermal, dens, roosts), and require ongoing clearing as part of vegetation management during operations. The Project Footprint, including the proposed pipeline right-of-way, power lines and temporary facilities, will be reclaimed following construction. Temporary construction workspace will be allowed to regenerate to natural vegetation communities. The permanent pipeline right-of-way (approximately 18 m wide) and power line rights-of-way will be periodically maintained to low vegetation heights over the life of the operating pipeline to facilitate monitoring and meet safety requirements. This will result in the long-term maintenance of forest habitat in earlier seral stages (herbaceous and shrub stages) within a portion of the Project Footprint. Some herbaceous and shrub-dominated vegetation communities (*e.g.*, grasslands, wetlands) are likely to regenerate following construction over the medium-term, while forest and some shrub habitats (*e.g.*, sage shrub-steppe) take longer to regenerate. During construction, sensory disturbance and resultant displacement of mammals from suitable habitat near the Footprint is a primary effect mechanism associated with a reduction in effective habitat and changes in movement patterns. Given the phased approach to construction, sensory disturbance associated with Project construction is expected to be relatively localized and of short-term duration. Sensory disturbance associated with noise and artificial light at the proposed facilities will be ongoing over the life of the operating pipeline, and will affect the effectiveness of habitat in proximity to those facilities, particularly for species that are sensitive to human disturbance. The proposed pipeline right-of-way and temporary facilities will be reclaimed following construction.

The Project will interact with mammal indicators via all three of the identified effects pathways, including changes in habitat, changes in movement and increased risk of mortality. Table 7.2.10-6 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the Project on the mammal indicators. The rationale used to evaluate the significance of the residual environmental effects is provided below.

TABLE 7.2.10-6

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON MAMMAL INDICATORS

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
1.	Wildlife Indicator – Grizzly Bear									
1(a)	Combined Project effects on grizzly bear resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	Grizzly Bear RSA	Short-term	Periodic	Long-term	Medium	High	Moderate	Not significant
2.	Wildlife Indicator – Woodland Caribou									
2(a)	Combined Project effects on woodland caribou resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	Caribou RSA	Short-term	Periodic	Long-term	Medium	High	High	Not significant
3.	Wildlife Indicator – Moose									
3(a)	Combined Project effects on moose resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	Wildlife RSA	Short-term	Periodic	Long-term	Low	High	Moderate	Not significant
4.	Wildlife Indicator – Forest Furbearers									
4(a)	Combined Project effects on forest furbearers resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	Wildlife RSA	Short-term	Periodic	Long-term	Low	High	Moderate	Not significant
5.	Wildlife Indicator – Coastal Riparian Small Mammals									
5(a)	Combined Project effects on coastal riparian small mammals resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	LSA	Short-term	Periodic	Long-term	Medium	High	Low	Not significant
6.	Wildlife Indicator – Bats									
6(a)	Combined Project effects on bats resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	LSA	Short-term	Periodic	Long-term	Low	High	Low	Not significant

Notes: 1 Refer to Section 7.2.10.2 for an explanation of spatial boundaries relevant to each indicator. LSA = Wildlife LSA.

2 Significant Residual Environmental Effect: defined as a high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Change in Habitat

The Project will change the amount of available effective habitat for mammals. The likely mechanisms for changes in effective mammal habitat include vegetation clearing and sensory disturbance (*e.g.*, human activity and noise). Concerns were identified during Aboriginal participation regarding the potential effects of the Project on mammal habitat, in particular, direct disturbance of riparian areas and mature and old forests, fragmentation, ungulate forage, rut and calving areas, habitat features such as beaver lodges, dens, game trials and mineral licks, and habitat for species at risk (*e.g.,* caribou), as well as indirect disturbance such as noise (Wildlife Technical Report of Volume 5C).

Clearing for construction and operations (*i.e.*, monitoring) of the Project will cause long-term maintenance of forest habitat in earlier seral stages (*e.g.*, herbaceous and shrub). Grassland and most shrub communities are expected to regenerate relatively quickly (medium-term) following construction and restoration, although community composition may take longer than 10 years to return to pre-construction conditions in some locations (*i.e.*, long-term). This change in vegetation within the Footprint will affect habitat suitability (*i.e.*, ability of the habitat to provide necessary requisites such as thermal/protective cover, denning, forage) and effectiveness (*i.e.*, utility of otherwise suitable habitat that may be influenced by human disturbance).

Clearing of the Footprint will reduce cover availability for wildlife and temporarily reduce forage availability for most mammals, with the exception of bats. Forest edges are often associated with elevated bat foraging activity, likely because they provide openings that provide movement corridors or accumulate insects (Hein *et al.* 2009, Jantzen 2012, Morris *et al.* 2010). The Project will likely create foraging habitat for bat species that forage for insects in the open (*e.g.*, little brown bats), but reduce foraging habitat for clutter-adapted bat species (*e.g.*, northern myotis) that forage in the understory of forests (Morris *et al.* 2010, Patriquin and Barclay 2003).

As cleared areas regenerate with early seral vegetation, forage availability will increase for some species (*e.g.*, browse for moose and deer; forage for bears). One study of collared grizzly bears demonstrated that grizzlies use pipeline rights-of-way and other linear disturbances (*e.g.*, roads and seismic lines) more than would be expected based on habitat availability (McKay *et al.* 2013). The study found that bears use pipeline rights-of-way for foraging and for travel. Anting was the primary foraging activity of grizzly bears on pipeline rights-of-way, particularly during the summer months (July and August), while herbaceous foraging, root digging sites and berry feeding sites were relatively common, and evidence of carnivory (*e.g.*, moose kill) was uncommon (McKay *et al.* 2013).

Forest furbearers such as marten and fisher are typically associated with old forest structure, riparian areas and densely forested wetlands, although a variety of forested ages and types are used (Thompson *et al.* 2012). Habitat use is associated with availability of coarse woody debris, large wildlife trees (snags) and canopy cover (particularly in winter), although marten and fisher will forage in a wide range of structural stages (BC MWLAP 2004b, Thompson *et al.* 2012). Habitat for wolverine is not easily delineated as a set of vegetative parameters and is closely tied to the distribution and abundance of food, as well as suitable habitat/structures for denning (BC MWLAP 2004b, Petersen 1997). Most studies of wolverine habitat indicate they require a suite of habitat variables that occur at larger spatial scales (*e.g.*, landscapes, regions) (BC MWLAP 2004b). Loss of forest habitat resulting from human development, particularly clear-cut forest harvest, is one of the main long-term threats to fisher and marten populations in BC (Hatler *et al.* 2003a,b, Proulx *et al.* 2003 in BC MWLAP 2004b, Weir 2003). Effects of habitat alteration on fisher depend on the intensity and scale (*e.g.,* landscape scale versus stand scale) at which the changes occur (BC MWLAP 2004b). Clearing for Project construction will result in habitat alteration at the patch or feature-level habitat scale, and is unlikely to preclude marten or fisher use of the modified habitat with the Footprint and adjacent areas, although individuals may expend more energy to find resources. Habitat loss resulting from human development is also a threat to wolverine populations (COSEWIC 2003a). Human activity including roads, infrastructure and back-country recreation negatively influence wolverine habitat selection (Lofroth and Krebs 2007). Some types of human activities that alter forested habitats may not result in negative changes to wolverine habitat (COSEWIC 2003a). For example, forest harvest practices that create a landscape matrix of uneven aged forest stands can diversify the prey base and maintain or improve wolverine habitat (COSEWIC 2003a). Conversely, habitat alterations that have negative effects on prey populations have negative indirect effects on wolverine habitat (COSEWIC 2003a).

Potential adverse Project effects on bats are primarily limited to the direct removal or degradation of roosting and hibernation habitat. Caves and mines as well as tall rock faces with deep fissures are likely the primary hibernation habitat for bats, and may also be used as roosting habitat during the summer (Lausen and Barclay 2006, Nagorsen and Brigham 1993). There are no caves or mines along the Project corridor, and steep topography indicative of rock faces will be avoided whenever practical during final pipeline routing. Tree-cavities are also extensively used for roosting by several bat species, and may be used as hibernacula in warmer areas of BC (Kalcounis-Rüppell *et al.* 2005, Nagorsen and Brigham 1993). Suitable tree-cavity roosting habitat is most often associated with old mixed or deciduous forests containing large-diameter decaying trees, which contain cavities, crevices or sloughing bark where bats can hide (Kalcounis-Rüppell *et al.* 2005). Concerns were identified during Aboriginal participation regarding the loss of wildlife trees, which provide habitat for cavity nesting and denning species (Wildlife Technical Report of Volume 5C). Some bat species (*i.e., Lasiurus* spp.) roost in the foliage among the canopy of trees (Nagorsen and Brigham 1993), which is not a limited habitat feature in the Wildlife LSA. Considering the limited available information on bat response to disturbance, the loss of tree-cavity roosting habitat is assumed to be limited to the direct area of mature and old forest within the Footprint. Quantitative change in tree-roosting habitat for bats is summarized in Table 7.2.10-7.

Disturbances that fragment habitat may have larger impacts than the area of direct habitat disturbance, if suitable habitat patch sizes are reduced below threshold levels that make them ineffective for certain species. For example, Snyder and Bissonette (1987) found that the majority of marten detections were in habitat patches ≥ 15 ha. The proposed pipeline corridor parallels existing linear corridors and will avoid construction of new access (*i.e.*, use existing access) to the extent feasible to reduce fragmentation of habitat patches.

Many mammal species are sensitive to human disturbance, and exhibit reduced use or avoidance of habitat in proximity to certain disturbance types (*i.e.*, zone of influence). This is referred to as a reduction in habitat effectiveness. Disturbance from anthropogenic noise created by roads has been found to have a negative effect on habitat use by grizzly bears, reducing habitat occupancy up to 500 m from active roads (Mace *et al.* 1996). The reduction in habitat effectiveness for carnivores such as wolverine and bears is expected to be limited to the construction period (*i.e.*, short-term).

Long-term reduction in habitat effectiveness adjacent to linear features may occur as caribou have been shown to partially avoid habitats near rights-of-way (Dyer 1999, Oberg 2001). Dyer *et al.* 2001 demonstrated that boreal woodland caribou avoid habitat within 250 m of roads and seismic lines, and within 1,000 m of industrial facilities such as well sites. Within the Wells Gray caribou range, the proposed pipeline corridor parallels the existing TMPL right-of-way, Highway 5, and an existing railway. It is likely that caribou avoid habitat along the proposed pipeline corridor, given that woodland caribou have demonstrated avoidance of such disturbance features (Dyer *et. al.* 2001). Long-term reduction in habitat effectiveness may result from the Project in the Groundhog caribou range where the proposed pipeline corridor deviates from the existing TMPL right-of-way and Highway 5 (for approximately 6.1 km). As is the case for most of the proposed pipeline corridor, this portion of the proposed corridor is located in the lower valley. Late winter construction is recommended to reduce the potential reduction in habitat effectiveness for Groundhog caribou associated with sensory disturbance from construction activities, since caribou tend to stay at higher elevations during the winter (Surgenor pers. comm.).

Reduced use or avoidance by moose of linear features such as roads, trails and seismic lines has been documented (Antoniuk *et al.* 2009, Collister *et al.* 2003, Ferguson and Keith 1985, Rolley and Keith 1980). Levels of human activity (*e.g.*, noise, traffic) affect moose response to these types of anthropogenic disturbance (Collister *et al.* 2003). Wasser *et al.* (2011) reported moose avoided linear features with no or unknown levels of human use and areas near primary roads. Avoidance effects were not apparent for moose beyond several hundred metres of exploration roads (Wasser *et al.* 2011). Sensory disturbance of moose can result in displacement to less suitable habitats. Although sensitive to human disturbance, moose will habituate to non-threatening and repetitive activities (Wiacek *et al.* 2002).

Open areas and young seral stage forests are low-value habitat for marten and fisher (Buskirk and Ruggiero 1994, Clark *et al.* 1987, Poole *et al.* 2004, Weir and Corbould 2010), which have been shown to avoid sites that lack overhead cover (*e.g.*, clear-cuts, meadows, burns, and wetlands) (Cheveau *et al.* 2013). Cleared areas may be avoided by marten and fisher due to increased predation risk, limited escape cover (*i.e.*, trees), and lower prey encounter and capture rates (Hargis *et al.* 1999, Thompson and Colgan 1994, Weir and Corbould 2010).

Pacific water shrew is found in and around riparian areas, especially within 50 m of the water's edge (Zevit and Welstead 2012). The primary threat to Pacific water shrew is the destruction or degradation of habitat (Craig *et al.* 2010). Primary causes of habitat loss include the removal of riparian vegetation, inadequate riparian buffers, and the loss of streams and wetlands that are not protected during development. Additional causes of habitat degradation include altering riparian habitat, edge effects, effects from runoff on water quality and clarity, and encroachment of development (Craig *et al.* 2010, Zevit and Welstead 2012). Both Olympic and Trowbridge's shrews are closely associated with forested communities with a well-developed litter layer and ground cover of shrubs and herbaceous plants. Olympic shrew may be more associated with riparian zones in and around streams and wetlands, while Trowbridge's shrew prefers more upland areas. Known populations of these species tend to be scattered and are potentially susceptible to local extirpation from habitat loss and fragmentation (Zevit 2012). Pacific water shrew, and to a lesser extent Olympic shrew, are riparian-dependent species and, therefore, many of the mitigation measures recommended for the protection of fish habitat (Table 7.2.10-3) will aid in protecting habitat for these species. However, riparian buffers imposed to protect fish habitat are likely insufficient in protecting the complete range of foraging and refugia requirements for these shrew species (Zevit 2012).

Different species, and even individuals within a species, are expected to respond differently to noise disturbances. Various factors affect an animal's response to noise, such as noise level, frequency distribution, duration, number of events, rate of onset, level of existing ambient noise, time of year or day, animal activity and location, animal age and gender. Noise effects on wildlife can potentially include habitat loss through avoidance, increased energy expenditure, changes in normal behaviours (*e.g.*, feeding) and impaired communication between individuals. Noise arising from construction and maintenance activities will potentially cause sensory disturbance to mammals. Sensory disturbance can cause increased energy expenditure and displacement of wildlife in the vicinity of the rights-of-way, potentially resulting in use of less suitable habitat in adjacent areas. Woodland caribou exposed to simulated petroleum exploration noise are reported to move faster and cross habitat boundaries substantially more than control caribou. The increased movement of caribou may result in higher energy expenditure and movement to different habitat types that provide cover or escape terrain (Bradshaw *et al.* 1997). Dyer *et al.* (2001) found that woodland caribou showed a higher level of avoidance of roads, seismic lines and oil and gas facilities (well sites) during late winter and calving seasons when human activity was higher. Moose have also been documented to avoid industrial developments during periods of human activity. Morgantini (1982, 1984 in Jalkotzy *et al.* 1997) documented avoidance of pipeline rights-of-way by moose during the construction periods of two pipeline projects.

The magnitude of potential Project effects on mammal habitat is expected to be higher for sensitive species. For example, woodland caribou are a Threatened species with declining populations and demonstrated adverse responses to disturbed habitats. Caribou are less resilient to habitat disturbance than some mammals that are more adaptable to disturbance, such as coyote, black bear or moose. The Project crosses proposed critical habitat for Pacific water shrew (Endangered under Schedule 1 of *SARA* and by COSEWIC) and early candidate critical habitat for Townsend's mole (Endangered under Schedule 1 of *SARA* and by COSEWIC) as identified by Environment Canada (Environment Canada 2013d). Pacific water shrew is at the northern limit of its distribution and is restricted to the southwest corner of BC in an area of rapid development and habitat change (COSEWIC 2006d). Pacific water shrews require riparian and wetland habitat at low elevations and this habitat specificity may increase the potential effects of habitat loss and fragmentation by limiting movement among habitat fragments (Pacific Water Shrew Recovery Team 2009).

Table 7.2.10-7 and Figure 7.2.10-1 summarize the predicted change in effective habitat for mammal indicators in the Wildlife LSA. Direct disturbance of mammal habitat resulting from the Project will be reduced by implementing the measures listed in Table 7.2.10-3 related to habitat loss and alteration, such as pre-construction surveys to identify site-specific habitat features (*e.g.*, mineral licks) and implementing buffers to avoid disturbance, minimizing the area of new footprint, and reclaiming the disturbed footprint to natural vegetation. Grassland and shrub dominated habitats are likely to regenerate following construction and reclamation in the medium-term. However, in forested areas direct alteration of mammal habitat is expected to extend over the long-term.

Reduced habitat effectiveness for mammal indicators associated with sensory disturbance from construction activities or site-specific maintenance during operations are reversible in short-term, once activities are complete. The mitigation measures listed in Table 7.2.10-3 related to sensory disturbance, such as avoiding sensitive timing windows wherever feasible, minimizing traffic and prohibiting recreational use of snowmobiles and ATVs on the work site, will reduce potential indirect effects of the Project on mammal habitat.

TABLE 7.2.10-7

PREDICTED CHANGE IN HABITAT FOR MAMMAL INDICATORS IN THE WILDLIFE LSA

Wildlife Indicator	Habitat/Life Requisite	Habitat Suitability Rating	Existing Conditions (ha)	Project Conditions (ha)	Incremental Change (ha)[2]	% Change

Notes: 1 The provincial model applied to the Pacific water shrew provides habitat capability. Refer to the Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C.

2 ↓ represents a decrease and ↑ represents an increase.

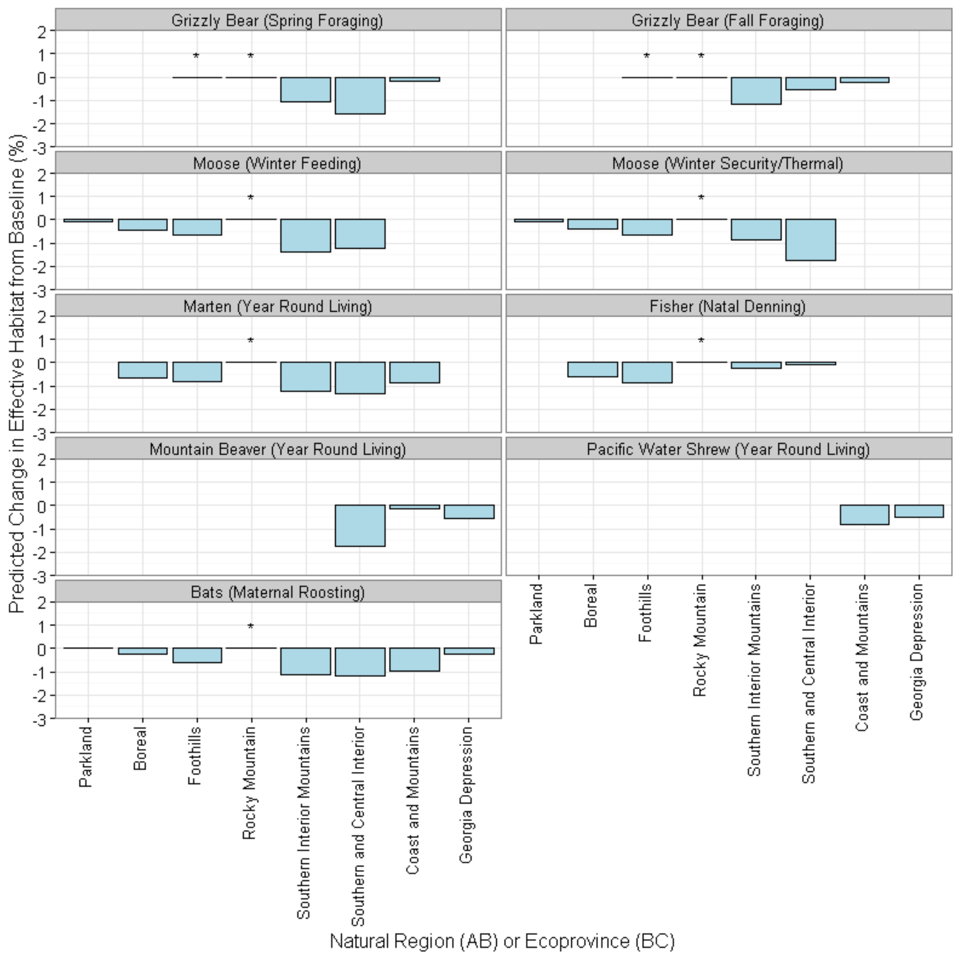

Figure 7.2.10-1 Predicted Change in Effective Habitat for Mammal Indicators
The change in effective habitat within the Wildlife LSA is presented as the percent change from baseline to Project conditions within each Natural Region in Alberta and Ecoprovince in BC. An asterisk (*) indicates spatial data are not available at the time of assessment to model the habitat within the identified Natural Region or Ecoprovince. Additional studies are planned to supplement the available data, which will be used to update habitat modelling, where needed.

Change in Movement

The Project may affect the movement of the mammal indicators. Physical barriers during construction (*e.g.*, pipe, soil, slash, and snow) may limit the movement of large mammals (*e.g.*, ungulates) (Morgantini 1985 in Hebblewhite 2008). Concerns identified during Aboriginal participation about potential effects of the Project included construction activities blocking game trails and restricting wildlife movement (Wildlife Technical Report of Volume 5C). However, this can be mitigated by leaving periodic openings in the strung pipe, soil and slash piles (Morgantini 1985 in Hebblewhite 2008). Most species are likely to move away from the Project area during construction (refer to sensory disturbance discussion above), but the displacement is expected to be short-term.

Changes in movement patterns during operations of the Project may occur in areas where new linear corridors are developed, and where the proposed pipeline is adjacent to existing linear corridors. The increased corridor width may cause an incremental barrier effect for some wildlife species. Aboriginal participants advised that clearing activities may alter the movement of wildlife (Wildlife Technical Report of Volume 5C). In some cases, linear developments have been shown to block, delay or deflect ungulate movements, potentially restricting or reducing access to some parts of their range (Harper *et al.* 2001). Studies on small mammal movements in the boreal forest have concluded that pipeline rights-of-way may act as barriers or filters to movement of flying squirrels, red squirrels and marten (Marklevitz 2003). Both marten and fisher typically do not venture into open areas without sufficient cover (Buskirk and Powell 1994, Powell and Zielinski 1994, Soutière 1979, Spencer *et al.* 1983). Collister *et al.* (2003) reviewed multiple studies on fisher habitat preference and dispersal, and concluded that fisher prefer large patches of contiguous forest habitat, avoid openings wider than 25 m and occur less frequently in stands less than 100 ha in size. Redistributing large-diameter slash (rollback) over select locations on the right-of-way (*e.g.*, where high levels of coarse woody debris occur prior to construction) is expected to reduce Project effects by providing cover and facilitating the movement of wildlife such as marten and fisher. Riparian areas may also provide important movement corridors for furbearers (Powell and Zielinski 1994) and small mammals that depend primarily on this habitat type (*e.g.*, Olympic shrew, Pacific water shrew) (Zivet 2012, Zivet and Welstead 2012). Trenchless watercourse crossings (where appropriate), measures to reduce riparian clearing during trenched watercourse crossings, and reclamation of disturbed riparian areas (Table 7.2.10-3) will reduce Project effects on mammal movement.

Research related to barrier effects of linear corridors on woodland caribou movement patterns is limited. One study found that seismic lines (which, like pipelines during operations, receive little human traffic or activity) do not create a barrier to caribou movement, although roads do (Dyer *et al.* 2002). Studies have concluded that pipelines do not create a movement barrier to boreal caribou (Carruthers and Jakimchuk 1987 in Dyer *et al.* 2002, Joint Pipeline Office 1999), except where they parallel roads with traffic (Curatolo and Murphy 1986 in Dyer *et al.* 2002). Dyer *et al.* (2002) suggest that roads and pipelines act in a synergistic fashion where they are parallel. Traffic levels, aversion to the physical barrier created by the forest opening along roads, and human predation are suggested by Dyer *et al.* (2002) as reasons why roads cause a barrier to caribou movement. Within the Wells Gray caribou range, the proposed pipeline corridor parallels the existing TMPL right-of-way, Highway 5, and an existing railway. Therefore, the corridor is likely already a barrier to caribou movement, given the conclusions of Dyer *et al.* (2002). The Project may create new movement barriers for caribou in the Groundhog caribou range where the Project deviates from the existing TMPL right-of-way and Highway 5 for approximately 6.1 km. The Project intersects one approved UWR for caribou in the Wells Gray caribou range (u-3-004). The General Wildlife Measures for this UWR (Table 7.2.10-3) are designed to maintain winter habitat for caribou. Caribou are likely to alter their movement to avoid the noise, activity and disturbance associated with construction activities. Project effects on caribou movement in the Wells Gray caribou range will occur during early to mid-winter, which corresponds to the period when caribou move from alpine and sub-alpine habitats to lower elevations in proximity to the proposed corridor and valley bottom (Surgenor pers. comm.).

Changes in movement patterns can also occur since some species may be attracted to the rights-of-way. The Footprint will create increased forage availability for some wildlife species once vegetation communities regenerate to early seral vegetation after reclamation (*e.g.*, grasses/shrubs and potential for greater berry productivity at clearing edges). This may attract some wildlife to the right-of-way and, therefore, affect their normal movement patterns. For example, moose have been shown to select habitat based on forage over security, often preferring early seral, shrub dominated habitats (Wasser *et al.* 2011) with lower densities of coniferous tree cover (Hebblewhite *et al.* 2010, Rempel *et al.* 1997, Schwartz and Franzmann 1991). Deer are also known to be attracted to recently cleared linear disturbances (Lyons and Jensen 1980) given the increased production of forage (Wallmo *et al.* 1972). Deer easily habituate to disturbance corridors, especially those with low human activity (Scott-Brown 1984). A study by Wasser *et al.* (2011) found positive selection by wolves for linear features and habitat with high suitability for deer. Rights-of-way may also provide travel routes for predators such as wolves (James 1999, Stuart-Smith *et al.* 1997, Thurber *et al.* 1994) and grizzly bears (McKay *et al.* 2013). James (1999) found that wolves traveled 2.9 times faster on linear corridors than through forest. McKay *et al.* (2013) found that collared grizzly bears tend to move faster on pipeline rights-of-way. Wolverines have also been found to diverge from their line of travel under forest cover when linear corridors with compacted snow were encountered, in order to follow the linear corridors, which provided easier travel routes (Wright and Ernst 2004). Bats have also been shown to use linear landscape features for movement, which provide navigational references and flight corridors for some bat species (Hein *et al.* 2009, Verboom and Huitema 1997).

Mitigation measures to reduce Project effects on mammal movement during construction and operations are described in Table 7.2.10-3. Limiting the length of open trench, maintaining periodic gaps in soil, slash, snow and pipe, where feasible, will limit barriers to mammal movement during construction. Redistributing large-diameter slash (coarse woody debris) over select locations on the right-of-way will contribute to maintaining habitat connectivity by reducing limitations to movement of furbearers (*e.g.*, marten, fisher) across the right-of-way.

Increased Mortality Risk

The Project may increase the risk of mortality for the mammal indicators. Potential mechanisms affecting mortality risk include clearing, blasting and vehicle collisions. In addition, linear corridors such as pipelines can increase the risk of mortality for some species by improving access, which can lead to increased predator numbers and efficiency, increased trapping, hunting and poaching, and human-wildlife conflicts. Concerns identified during Aboriginal participation about potential impacts of the Project on mortality risk included increased access for hunters and predators, increased line-of-sight altering predator-prey dynamics and potential pipeline spills and leaks. Participants raised concerns about caribou and caribou habitat, and reported that local caribou populations have been decreasing as the use of snowmobiles, industrial and urban development, overhunting and climate change have increased over time, and that large herds of caribou have not been seen in decades (Wildlife Technical Report of Volume 5C).

Linear corridors create improved access for predators such as wolves, which are known to travel along pipeline rights-of-way. Several studies have found that linear corridors are attractive to wolves as easy travel routes (James 1999, Stuart-Smith *et al.* 1997, Thurber *et al.* 1994) and may affect wolf-prey dynamics (Bergerud *et al.* 1984, Edmonds and Bloomfield 1984, Rohner and Kuzyk 2000). Wolves travel faster along linear disturbances (James 1999, McKenzie *et al.* 2012) and encounter rates between wolves and caribou have been shown to increase near linear features (Whittington *et al.* 2011). Linear corridors created by the proposed pipeline may increase wolf predation on ungulates (*e.g.*, moose, deer), since both prey (ungulates) and predators (wolves) will likely be attracted to revegetating linear corridors. Whittington *et al.* 2011 suggest that the influence of anthropogenic linear feature density on predation rates may be as important in mortality of ungulates (particularly caribou) as the density of predators. A recent study found that roads increased predation risk for mountain caribou, but early seral habitat and edge created by logging, power lines and wildfire did not (Apps *et al.* 2013). The study showed that with the exception of roads, early seral/edge habitats influence caribou predation risk less than habitat variables such as elevation, terrain conditions (*i.e.* complexity, slope), and variation in canopy cover (Apps *et al.* 2013). Vulnerability to predation for caribou increases as they move to lower elevations habitats that are selected by primarily prey (*i.e.*, moose and deer) regardless of habitat disturbance on the landscape. Vulnerability has also been shown to increase in rugged terrain and narrow valleys rather than wide valleys or plateau areas (Apps *et al.* 2013). This suggests that aside from roads, the functional response of predators to habitat changes on the landscape is less relevant than the population-level numerical response of predators to their primary prey (Apps *et al.* 2013). Aboriginal participants requested that willow be planted during reclamation at identified locations, in order to reduce line-of-sight for predators along the pipeline right-of-way (Wildlife Technical Report of Volume 5C). Willow planting can be a useful reclamation tool and will be implemented in select locations (*e.g.*, riparian area) outside of caribou range. Conifer seedling planting is an alternate measure that may be implemented to restore habitat, break line-of-sight and control access in selection locations. By planting shrubs and/or trees at select locations to restore woody vegetation cover and provide breaks in line-of-sight, and by redistributing coarse woody debris to limit predator mobility along the Footprint, the magnitude of residual effects associated with increased mammal mortality risk due to predation will be reduced. In addition, the creation of new linear corridors will be reduced by using existing access, and temporary access will be decommissioned and reclaimed following construction.

Linear corridors such as pipeline rights-of-way have the potential to increase mortality rates through hunting and trapping pressures by creating new access. Hunting is a major factor for grizzly bear mortalities in BC (McLellan *et al.* 2000). Road density thresholds related to grizzly bear mortality are discussed further in Section 8.0. Aboriginal participants noted that an increase in human presence and declines in the salmon population have also caused declines in the regional grizzly bear population (Wildlife Technical Report of Volume 5C). Hunting is also a key mortality factor for ungulates such as moose. Moose populations are considered more sensitive to overharvest and other sources of mortality than to habitat loss and fragmentation (Antoniuk *et al.* 2009). Aboriginal participants shared concerns regarding increased access for moose hunters (Wildlife Technical Report of Volume 5C). Trapping has been an important factor influencing fisher (Powell and Zielinski 1994, Weir 2003), marten (Buskirk *et al.* 2012, Hatler *et al.* 2003a) and wolverine (Lofroth and Ott 2007) populations. Fisher populations in eastern portions of their range have been found to have low to intermediate resiliency to trapping pressure, which means they generally have a moderate capability to recover from reduced population numbers (Banci and Proulx 1999 in Weir 2003). As noted above, new access for the Project will be minimized by using existing access wherever feasible, and temporary access will be decommissioned and reclaimed following construction. Mitigation to control access on the Footprint will be implemented (Table 7.2.10-3), including but not limited to planting tree seedlings and/or shrubs in select locations to facilitate rapid regeneration of natural vegetation and block sight-lines, and blocking access entry points by mounding, woody debris rollback, boulder barriers or earth berms. In addition to hunting and trapping pressure, increased human access increases the risk of human-bear conflicts that can result in animals being relocated or destroyed. Implementation of the Wildlife Conflict Management Plan (Table 7.2.10-3) is expected to prevent any direct bear mortalities associated with the construction and operations of the Project.

The Project also has the potential to affect the mortality risk of some mammal indicators through vegetation clearing. For example, the Project may result in the inadvertent felling of or disturbance to occupied fisher or marten natal dens (where parturition occurs) and maternal dens (where kits are raised). Fisher typically den in cavities in trees and logs (Powell and Zielinski 1994). Marten also typically den in cavities in trees and logs or in piles of debris, rock crevices, and underground burrows (Hatler *et al.* 2003a, Powell and Zielinski 1994, Thompson *et al.* 2012). Fisher parturition occurs in late winter, and natal dens may be occupied between February and May (Weir 2003, Powell and Zielinski 1994) after which kits are moved to maternal dens for the summer (Weir 2003). Marten parturition also occurs in late winter (Banfield 1974). Fishers and marten can be highly sensitive during the denning period. Fishers have been reported to move kits to different dens when disturbed (Powell and Zielinski 1994), however, availability of alternate den sites may be limiting (Powell *et al.* 1997). Therefore, disturbance during the denning period has potential to increase risk of mortality of kits. Similarly, disturbance of hibernation habitat (*e.g.*, bear dens, bat hibernacula) during winter construction has potential to increase mortality risk for hibernating mammals. The proposed mitigation regarding buffers for bat hibernacula, bat maternity roosts, and bear dens will help minimize mammal mortality from vegetation clearing (Table 7.2.10-3).

Vehicle traffic due to construction and operations of the Project may also increase the risk of mammal mortality due to vehicle collisions. With posting of low traffic speeds, signage and education of construction and operations contractors and employees, risk of mammal injury or mortality associated with vehicle collisions is not expected to increase substantially as a result of the Project.

Summary of Effects Characterization Rationale for Mammal Indicators

A summary of the rationale for the effects characterization for the mammal indicators is provided below. Environmental and/or regulatory standards used in the evaluation of magnitude are provided in Table 7.2.10-5 (ecological context for each mammal indicator) and Section 7.2.10.4 (regulatory guidelines). The criteria rating and rationale for duration, frequency, reversibility and probability are similar for all of the mammal indicators:

- Duration: short-term – the events causing effects are construction and operational activities (*e.g.*, monitoring, vegetation management and site-specific maintenance), the latter of which are limited to any 1 year during operations.
- Frequency: periodic – the events causing effects (*i.e.*, clearing of the Footprint, traffic and activity) will occur during construction and intermittently during operations for monitoring, vegetation control and maintenance.
- Reversibility: long-term – effects are reversible in the long-term following decommissioning and abandonment, once native vegetation regenerates over the Project Footprint.
- Probability: high – the Project will alter habitat, cause sensory disturbance and potentially increase mortality risk to affect the indicator.

The criteria rating and rational for spatial boundary, magnitude and confidence vary, and are provided below for each mammal indicator.

<u>Grizzly Bear</u>

- Spatial Boundary: Grizzly Bear RSA – habitat changes (*e.g.*, clearing) and alteration of movement (*e.g.*, avoidance of construction) will be limited to the Wildlife LSA; however, changes in mortality risk (*e.g.*, increased access, traffic) are assessed at the regional scale.
- Magnitude: medium – grizzly bear is a species of conservation concern provincially and federally, largely due to extensive range and population reductions influenced by habitat development and fragmentation, and human related conflicts and mortality. Clearing for Project construction and operation will create early seral habitat that will have a small increase in suitable foraging habitat for grizzly bear; however, mortality risk is known to be high for grizzly bears along linear corridors. The proposed mitigation measures, including development and implementation of a Wildlife Conflict Management Plan, and measures to reduce new access and control access where it cannot be avoided, are consistent with regional resource management objectives and strategies, and will reduce the magnitude of Project effects on grizzly bear to medium.
- Confidence: moderate – the assessment is based on a good understanding of cause-effect relationships and relevant data. Limitations and uncertainty associated with available data pertinent to the Project area reduce the confidence level to moderate.

<u>Woodland Caribou</u>

- Spatial Boundary: Caribou RSA – habitat changes (*e.g.*, clearing) and alteration of movement (*e.g.*, avoidance of construction) will be limited to the Wildlife LSA; however, changes in mortality risk (*e.g.*, increased access, traffic) are assessed at the regional scale.
- Magnitude: medium – Despite the relatively low value of the habitat within the proposed corridor for caribou (due to its low elevation location and existing disturbances), the Project is expected to improve habitat conditions for moose forage and for wolves (prey availability, ease of travel). Wolves have been documented using the existing TMPL right-of-way in the Caribou RSA. Wolves are suggested as a primary factor in the decline of mountain caribou in the Caribou RSA. Changes in moose-wolf-caribou interactions are likely the primary mechanism by which the Project will potentially affect caribou. Mitigation beyond standard measures is warranted to address the Project's residual effect on woodland caribou (*e.g.*, planting conifer seedlings in strategic locations within the Project Footprint, and potentially the existing TMPL right-of-way). Trans Mountain will work with provincial regulatory authorities, tenure holders and other stakeholders to identify opportunities to address potential residual Project effects on caribou habitat. Trans Mountain will work with regulatory authorities for the deviation from the General Wildlife Measures set out by the UWR Order, if required. Implementation of appropriate mitigation is expected to address the Project's residual effect and contribution to cumulative effects.
- Confidence: high – the assessment is based on a good understanding of cause-effect relationships and relevant data.

Moose

- Spatial Boundary: Wildlife RSA – habitat changes (*e.g.*, clearing) and alteration of movement (*e.g.*, avoidance of construction) will be limited to the Wildlife LSA; however, changes in mortality risk (*e.g.*, increased access, traffic) are assessed at the regional scale.

- Magnitude: low – moose are highly valued as a game species and for traditional and cultural purposes, but do not have conservation status designations of concern, either provincially or federally. Moose populations in Alberta are secure. Moose populations in BC appear to be generally stable, though recent declines have been observed. BC MFLNRO actively monitors and manages moose populations. Adverse residual effects of the Project on moose will be reduced through mitigation to use existing access wherever feasible, reclaim the disturbed Footprint to native vegetation, limit construction activities in winter range during winter and control access. These measures are consistent with regional resource management objectives and strategies, and will reduce the magnitude of Project effects on moose to low.

- Confidence: moderate – the assessment is based on a good understanding of cause-effect relationships and relevant data. Limitations and uncertainty associated with available data pertinent to the Project area reduce the confidence level to moderate.

Forest Furbearers

- Spatial Boundary: Wildlife RSA – habitat changes (*e.g.*, clearing), alteration of movement (*e.g.*, avoidance of construction and cleared Footprint) and direct mortality risk (*e.g.*, disturbance of natal den) are primarily limited to the Wildlife LSA. However, the study area is expanded to the Wildlife RSA to capture effects on mortality risk associated with increased access (*e.g.*, hunting pressure) and traffic (*e.g.*, collisions with construction traffic).

- Magnitude: low – there are species with special conservation concern within the forest fur-bearer indicator group (*e.g.*, fisher, wolverine). These species are managed as furbearers (*i.e.*, for harvest) in BC and Alberta. Habitat loss (forest clearing from human development) and trapping are primary threats to fur-bearer populations. Mitigation measures to reduce new access, reduce the area of disturbance (particularly in riparian areas), reclaim disturbed areas to natural vegetation, and distribute coarse woody debris over the Footprint, are expected to reduce the magnitude of residual Project effects on forest furbearers to low.

- Confidence: moderate – the assessment is based on a good understanding of cause-effect relationships and relevant data. Limitations and uncertainty associated with available data pertinent to the Project area reduce the confidence level to moderate.

Coastal Riparian Small Mammals

- Spatial Boundary: Wildlife LSA – habitat changes (*e.g.*, clearing), alteration of movement (*e.g.*, fragmentation) and direct mortality risk (*e.g.*, disturbance of nests/den) are primarily limited to the Wildlife LSA.

- Magnitude: medium – several coastal riparian small mammal species with conservation status of concern occur in the Wildlife LSA. The Project crosses proposed critical habitat for Pacific water shrew and early candidate critical habitat for Townsend's mole (Environment Canada 2013d). The proposed mitigation to reduce residual Project effects on riparian habitat for small mammals (*e.g.*, minimize the Footprint in riparian habitats, avoid disturbance of site-specific habitat features, avoid wildlife mortality and reclaim disturbed areas within the Project Footprint) are consistent with provincial regulatory guidelines. Consultation with Environment Canada regarding the Project's interaction with the proposed and candidate critical habitats, and an appropriate approach for mitigating effects, has been initiated and is ongoing. It is anticipated that, if warranted, an appropriate mitigation strategy will be developed to reduce the magnitude of residual Project effects on coastal riparian small mammals. With application of the mitigation measures, the residual effect of the Project on coastal riparian small mammals is concluded to be of medium magnitude.

- Confidence: low – the assessment is based on an incomplete understanding of cause-effect relationships (*i.e.*, limited research and literature is available). Data used to inform the effects assessment is primarily from outside the Project area. There are limitations and uncertainty associated with the data pertinent to the Project area.

<u>Bats</u>

- Spatial Boundary: Wildlife LSA – expected Project effects on bats are limited to the Wildlife LSA.
- Magnitude: low – several bat species with conservation status of concern occur in the Wildlife LSA. Known threats to bat populations are limited (*e.g.*, wind energy development, white-nose syndrome). Rock features that could potentially provide bat rock-roosting and hibernation habitat will be avoided where feasible during Project routing and siting. Direct habitat disturbance associated with clearing mature and old forests is likely the primary mechanism of Project interaction with bats. Direct habitat disturbance associated with clearing mature and old forests will be reduced by minimizing the Project Footprint, avoiding identified habitat features, and reclaiming the Footprint to natural vegetation, such that residual Project effects on bats are expected to be of low magnitude.
- Confidence: low – the assessment is based on a limited understanding of cause-effect relationships (*i.e.*, limited research and literature is available) and data from outside the Project area. There are limitations and uncertainty associated with the data pertinent to the Project area.

7.2.10.10 Significance Evaluation of Potential Residual Effects on Bird Indicators

The indicators selected to assess potential Project effects on birds includes a combination of habitat-based community indicators, species groups and individual species indicators, including grassland/shrub-steppe birds, mature/old forest birds, early seral forest birds, riparian and wetland birds, wood warblers, short-eared owl, rusty blackbird, flammulated owl, Lewis's woodpecker, Williamson's sapsucker, western screech-owl, great blue heron, spotted owl, bald eagle, common nighthawk, northern goshawk and olive-sided flycatcher. Detailed species accounts (including species lists for the community indicators) are described in the Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C.

Relevant regulatory guidelines, information identified during Aboriginal participation in field studies, and ecological context was considered in the characterization of potential residual effects for the bird indicators. A summary of regulatory guidelines is provided in Section 7.2.10.4. In general, the planning documents relevant to the proposed pipeline corridor recommend conserving important bird habitat, particularly for species at risk or species of special management concern (Appendix E in Wildlife Technical Report of Volume 5C). In Alberta, the proposed pipeline corridor crosses Sensitive Raptor Range for bald eagle and sharp-tailed grouse range (AESRD 2013d). The proposed pipeline corridor is also in the vicinity of three identified trumpeter swan lakes (200 m, 400 m and 700 m from the proposed pipeline corridor) (AESRD 2013d). In BC, the proposed pipeline corridor intersects a LTOHA for spotted owl (WHA 2-498), proposed critical habitat for Williamson's sapsucker, and early candidate critical habitat for Lewis's woodpecker (Environment Canada 2013d). The Wildlife Technical Report in Volume 5C provides additional information regarding proposed and candidate critical habitats. Consultation with Environment Canada and BC MFLNRO regarding the Project's interaction with these sensitive habitat areas and an appropriate approach for mitigating effects has been initiated and is ongoing.

The compilation of ATK, including the collection of TEK through Aboriginal field participation, as well as the engagement process provided valuable information about wildlife along the proposed pipeline corridor, and identified concerns and potential effects of the Project. Engagement details regarding wildlife and Aboriginal participation in field studies are provided in the Wildlife Technical Report of Volume 5C, and this information is included and considered throughout the effects assessment for bird indicators. The Project crosses the Cheam Lake Wetlands Regional Park, which provides habitat for many bird species including great blue heron, bald eagle, and riparian and wetland bird species.

Information on the ecological context for each bird indicator (*e.g.,* species status, population trends, known threats, best management practices and conservation strategies) is provided in Table 7.2.10-8. The purpose of providing ecological context for each indicator is to provide an indication of the resilience of each indicator to disturbance effects.

TABLE 7.2.10-8

ECOLOGICAL CONTEXT SUMMARY FOR BIRD INDICATORS

Indicator	Ecological Context
Grassland/ shrub-steppe birds	• The grassland and shrub-steppe bird community indicator includes bird species known to inhabit BC's southern interior grassland/shrub-steppe communities. The indicator is defined to include 41 species (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C); including the following species of conservation concern (BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - barn swallow (Threatened by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - bobolink (Threatened by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - Brewer's sparrow, *breweri* ssp. (Red-listed in BC; Conservation Framework Priority 2); - burrowing owl (Endangered under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 2); - common nighthawk (Threatened under Schedule 1 of *SARA* and by COSEWIC); - horned lark, *merrilli* ssp. (Blue-listed in BC); - lark sparrow (Red-listed in BC; Conservation Framework Priority 2); - Le Conte's sparrow (Blue-listed in BC); - Lewis's woodpecker (Threatened under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 2); - long-billed curlew (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - prairie falcon (Red-listed in BC; Conservation Framework Priority 2); - sage thrasher (Endangered under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 1); - sharp-tailed grouse, *columbianus* ssp. (Blue-listed in BC; Conservation Framework Priority 2); - short-eared owl (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); and - Swainson's hawk (Red-listed in BC; Conservation Framework Priority 2). • Grassland birds are in decline in every area of Canada where they have been studied (North American Bird Conservation Initiative 2012). • Despite the limited distribution of grassland ecosystems in BC, these habitats support a large number of the province's endemic bird species, and many of these species are grassland-obligates. The vast majority of grassland-associated birds nest on the ground (McCracken 2005), and this aspect of their ecology makes them more sensitive to anthropogenic activities than forest-dwelling birds (McCracken 2005). Based on their ground-nesting tendencies, incubating females and their offspring are also vulnerable to mammalian predators (McCracken 2005). Therefore, factors that increase the abundance or search efficiency of such predators are also expected to affect grassland bird abundance. During the summer, the diet of many grassland birds is dominated by insects, though some species like the horned lark are primarily granivorous (seed-eaters). • Grassland/shrub-steppe birds are associated with arid landscapes dominated by grasses; low shrubs (*e.g.*, big sagebrush) can be a major component of these ecosystems. Both migratory and non-migratory (*e.g.*, sharp-tailed grouse) species are included within the grassland/shrub-steppe bird community, and therefore, some species are present in the Wildlife LSA year-round. • Throughout North America, grassland and shrub-steppe associated birds have been suffering marked declines, and as a community, their rate of decline outpaces that of any other species guild. These declines are principally related to the loss of grassland ecosystems due to forest and dense shrub encroachment (from fire-suppression), agricultural development, industrial development, and conversion of grasslands for urban uses (Brennan and Kuvlesky 2005). • The Lac du Bois Grasslands area, specifically Lac du Bois Grasslands Protected Area, contains the greatest number of sharp-tailed grouse leks in the Thompson Basin, and provides winter habitat for sharp-tailed grouse. Sage thrasher has also been recorded in the Lac du Bois Grasslands Protected Area (Grasslands Conservation Council of British Columbia 2009). • The proposed pipeline corridor crosses burrowing owl range in the Thompson-Nicola region (BC CDC 2013). Re-introductions have occurred annually in several locations including Lac du Bois Grasslands Protected Area, Knutsford, Hamilton Commonage, and Quilchena. In the Lac du Bois Grasslands Protected Area, the proposed pipeline corridor is located approximately 1,400 m from the nearest burrowing owl re-introduction site (Grasslands Conservation Council of BC 2009). The program has not yet established a self-sustaining population. In 2005, 84 owls were released and they fledged 100 owlets. Approximately 15 owls returned from migration the following year (Environment Canada 2012). The current population of burrowing owls in the region is unknown; however, re-introduction programs continue (Burrowing Owl Conservation Society of BC 2009, Environment Canada 2012). The recovery goal in the Recovery Strategy for the Burrowing Owl (*athene cunicularia*) in Canada is to reverse the population decline in Canada and maintain a self-perpetuating, well-distributed population (*i.e.*, 800 pairs in 5 years) by improving knowledge of annual population changes; mitigating factors contributing to population declines and habitat loss; optimize nesting success and fledging rate; improve survival on Canadian breeding grounds; re-establish wild breeding populations; increase awareness and conservation (Environment Canada 2012). • The proposed pipeline corridor intersects long-billed curlew habitat in upland grassland habitats in BC. The goal of the *Management Plan for the Long-billed Curlew (Numenius americanus) in Canada* is to maintain or increase the recent breeding distribution of the long-billed curlew in Canada. This involves maintenance and improvement of habitat for breeding and migrating (Environment Canada 2013g).

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Grassland/ shrub-steppe birds (cont'd)	• Identified Wildlife Species Accounts for grassland/shrub-steppe bird community species, including the long-billed curlew, prairie falcon, Brewer's sparrow, grasshopper sparrow, sharp-tailed grouse, and sage thrasher, recommend the following provisions and management recommendations: protection of large areas of continuous dry shrub-steppe and sagebrush habitats; and maintain and maximize connectivity of suitable habitats (sagebrush habitats, aspen-dominated ravines). Common recommended general wildlife measures include: establishment of WHAs to protect and maintain suitable breeding, nesting and fledging/brood rearing habitat; minimization of disturbance in grassland and sagebrush habitats during breeding season; maintenance of adjacent riparian and forest habitats; and prevention of forest encroachment. Specific measures include avoiding road and trail development; limiting road use during critical times during the breeding season (April 1 to July 15); not using pesticides; avoiding concentrations of livestock during the breeding season; and maintaining large (>2 ha) patches of sagebrush by managing livestock impacts (BC MWLAP 2004b). • The *Guidelines for Raptor Conservation* recommend the following management guidelines for species, including Swainson's hawk, in grassland and shrub-steppe habitats: protect trees, snags, cliffs, or other roosting and perching structures; retain natural open habitats to provide security cover for both prey species and ground nesting raptors; avoid mowing of fields during the nesting season; and maintain undisturbed buffers of up to 500 m around nest sites (BC MOE 2013e). • Context for short-eared owl and Lewis's woodpecker are provided below. • Table 7.2.10-10 provides a summary of the predicted change in effective grassland/shrub-steppe bird habitat as a result of the Project.
Mature/old forest birds	• The mature/old forest bird community indicator includes bird species known to inhabit mature and old forests, and potentially occur in the Wildlife LSA. The indicator is defined to include 91 species (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C), including the following species of conservation concern (AESRD 2012a, ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - Baltimore oriole (Sensitive in Alberta); - band-tailed pigeon (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - barred owl (Yellow-listed in BC; Sensitive in Alberta, Special Concern by Alberta's ESCC); - black-backed woodpecker (Yellow-listed in BC; Sensitive in Alberta); - black-throated green warbler (Sensitive in Alberta; Special Concern by Alberta's ESCC); - broad-winged hawk (Blue-listed in BC; Sensitive in Alberta); - brown creeper (Yellow-listed in BC; Conservation Framework Priority 1; Sensitive in Alberta); - Canada warbler (Threatened under Schedule 1 of *SARA* and by COSEWIC; Sensitive in Alberta); - Cape May warbler (Sensitive in Alberta; In Process [previously Special Concern] by Alberta's ESCC); - flammulated owl (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - great gray owl (Yellow-listed in BC; Sensitive in Alberta); - least flycatcher (Yellow-listed in BC; Sensitive in Alberta); - northern goshawk, *atricapillus* ssp. (Yellow-listed in BC; Conservation Framework Priority 3; Sensitive in Alberta); - northern goshawk, *laingi* ssp. (Threatened under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 1); - northern pygmy-owl (Yellow-listed in BC; Conservation Framework Priority 3; Sensitive in Alberta); - pileated woodpecker (Yellow-listed in BC; Sensitive in Alberta); - spotted owl (Endangered under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 2); - western screech-owl, *kennicotti* ssp. (Special Concern under Schedule 1 of *SARA*; Threatened by COSEWIC; Blue-listed in BC; Conservation Framework Priority 1); - western screech-owl, *macfarlanei* ssp. (Endangered under Schedule 1 of *SARA*; Threatened by COSEWIC; Red-listed in BC; Conservation Framework Priority 1); - western tanager (Yellow-listed in BC; Sensitive in Alberta); - western wood-pewee (Yellow-listed in BC; Conservation Framework Priority 2; Sensitive in Alberta); and - Williamson's sapsucker (Endangered under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2). • The mature/old forest birds includes species that are most commonly associated with mature, structurally complex forests, characterized by multi-storied canopies and well-developed understories. Waterhouse *et al.* (2003) suggest that representation of old-growth forest by BGC Zone, forest stand structure, and elevational gradient helps maintain bird diversity. • Context for wood warblers, flammulated owl, Williamson's sapsucker, western screech-owl, spotted owl and northern goshawk are provided below. • Table 7.2.10-10 provides a summary of the predicted change in effective mature/old forest bird habitat as a result of the Project.

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Early seral forest birds	• The early seral forest bird community indicator includes species that inhabit young forest habitats and potentially occur in the Wildlife LSA. The community indicator is defined to include 86 bird species (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C), including the following species of conservation concern (AESRD 2012a, ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - Baltimore oriole (Sensitive in Alberta); - band-tailed pigeon (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - black-backed woodpecker (Yellow-listed in BC; Sensitive in Alberta); - Cape May warbler (Sensitive in Alberta; In Process [previously Special Concern] by Alberta's ESCC); - Clark's nutcracker (Yellow-listed in BC; Sensitive in Alberta); - least flycatcher (Yellow-listed in BC; Sensitive in Alberta); - northern pygmy-owl (Yellow-listed in BC; Conservation Framework Priority 3; Sensitive in Alberta); - olive-sided flycatcher (Threatened under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2; May Be at Risk in Alberta); - pileated woodpecker (Yellow-listed in BC; Sensitive in Alberta); - sooty grouse (Blue-listed in BC; Conservation Framework Priority 2); - western tanager (Yellow-listed in BC; Sensitive in Alberta); and - western wood-pewee (Yellow-listed in BC; Conservation Framework Priority 2; Sensitive in Alberta). • A similar group consisting of early seral forest breeding birds has been analysed by the North American Breeding Bird Survey (Breeding Bird Surveys); of the birds showing substantial population changes (increasing or decreasing) in North America, 77% (35/46) have been declining (Environment Canada 2013h). • Early seral forests are composed of young shade-intolerant trees and large shrubs that have attained dominance over other vegetation. Such forests are often characterized by their high stem density, broadleaf dominance, and lack of mature trees. In later stages of succession early seral stands undergo self-thinning and vertical structure can become evident (Resource Inventory Committee 1998). These stages of early seral cover support a variety and abundance of birds (Ellis *et al.* 2012). • A unique feature of early seral forests is that they are relatively short-lived under natural disturbance regimes (Bunnell 1995). Under contemporary forest management practices, the life-span of this successional stage is being further shortened and their overall structure is altered as well (Betts *et al.* 2010). In the conifer-dominated portions of the Pacific Northwest, early successional forests typically contain an abundant and long-lasting broadleaf component (Resource Inventory Committee 1998). • Most of the birds inhabiting young forests are leaf-gleaning insectivores (Ellis and Betts 2011). Since broadleaf species promote higher densities of arthropods than do conifers (Hagar 2007, Hammond and Miller 1998), early seral bird abundance increases as broadleaf species become more prolific (Ellis *et al.* 2012). There is also some recent evidence from the Pacific Northwest, that bird species diversity is higher on early seral sites with productivity (McWethy *et al.* 2009, Verschuyl *et al.* 2008). • Early successional forests are gradually being reduced in spatial extent due to intensive management for conifers, fire suppression, and public demand for old-growth forests (Kennedy and Spies 2005). A recent study suggests that the reductions in the extent of early seral forests may be responsible for declines seen in various bird species of the Pacific Northwest (Betts *et al.* 2010). • There currently are no recovery plans for the birds in this indicator (BC MOE 2013f). • Context for Cape May warbler and olive-sided flycatcher are provided below. • Table 7.2.10-10 provides a summary of the predicted change in effective early seral forest bird habitat as a result of the Project.
Riparian and wetland birds	• The riparian and wetland bird community indicator is defined to include 158 bird species, including 35 species of conservation concern. The riparian and wetland bird community includes but is not limited to waterfowl, grebes, pelicans, cormorants, herons, rails, gulls, flycatchers, songbirds and raptors, listed in detail in the Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C. • Species in this indicator rely on wetlands, lakes, watercourses and the associated riparian areas. Aquatic habitats include watercourses, wetlands with varying amounts of emergent vegetation, swamps, bogs, fens, lakes and lake margins. Wetland surveys for the Project identified 638 wetlands (approximately 94.4 km and 570.4 ha) crossed by the proposed pipeline corridor, comprising approximately 9.6% of the length of the proposed corridor (Section 7.2.8.3). Wetlands crossed by the proposed corridor include 141 basin marshes, 67 riparian marshes, 4 lacustrine marshes, 7 slope marshes, 2 hummock marshes, 104 flat swamps, 78 riparian swamps, 2 discharge swamps, 6 slope swamps, 45 basin shallow open water, 19 riparian shallow open water, 13 basin fens, 26 horizontal fens, 13 riparian fens, 2 channel fens, 1 feather fens, 1 slope fen and 1 basin bog. • The primary threats to riparian and wetland birds including both species at risk (*e.g.,* Canada warbler, harlequin duck) and more common species (*e.g.,* spotted sandpiper, dippers) are habitat/wetland loss to development, urban expansion, and livestock degradation, as well as pollution and predation (COSEWIC 2008b). • The proposed pipeline corridor intersects potential yellow rail habitat on the Edmonton to Hinton Segment. Field surveys in 2013 did not detect any yellow rails (Wildlife Technical Report of Volume 5C). The goal of the *SARA* management plan for yellow rail is to protect and maintain the population and habitat of yellow rail in Canada. Recommended management measures include population monitoring and assessment, habitat conservation and management, and outreach (Environment Canada 2013j).

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Riparian and wetland birds (cont'd)	• In the Identified Wildlife Species Account for sandhill crane, management objectives include establishment of WHAs to maintain breeding habitats and recommended general wildlife measures. The proposed pipeline corridor does not encounter any WHAs for sandhill crane. The recommended general wildlife measures are maintenance of the structural integrity of emergent vegetation in and around nesting areas to provide cover and nesting habitat, maintenance vegetated screen around breeding wetlands, minimizing disturbance and access during the breeding season (April 1 to September 21), minimizing human access to important staging areas during the migratory period (April and September/October), and restoration of historical water regimes to wetland areas that have been drained (BC MWLAP 2004b). • Management guidelines for American bittern recommend the following measures in known breeding habitat (Gill 2007): establish a 30 m restricted zone around the wetland in which no forestry activities are permitted within the restricted zone, nor entry during the breeding season (March 1 to September 1) in order to prevent disturbing nesting birds; establish a management zone (200 m to 350 m) around the restricted zone to maintain seclusion of the wetland and minimize disturbance during the breeding season (March 1 to September 1, including harvest, salvage, hauling, and road construction); implement erosion and sediment controls in the management zone; do not use pesticides or herbicides; and do not remove beaver dams where flood areas are being used by American bitterns. • In the status report for trumpeter swans in Alberta, the recommended management strategies include a reintroduction program and implementation of land use legislation such as a 500 m buffer on identified trumpeter swan lakes that precludes long term development (roads, wells, pipelines) and flying restrictions over trumpeter swan lakes during breeding season (April 1 to September 30) (James 2000). Regulatory guidelines for disturbance activities near trumpeter swan nesting habitat in Alberta recommend a year-round disturbance setback distance of 500 m from the bead and shore of identified waterbodies and/or watercourses, and 800 m between April 1 and September 30 (Government of Alberta 2013a). • Recommendations from the BC *Develop with Care Guidelines* for riparian and wetlands habitats include: maintaining riparian vegetation cover including trees, shrubs, and ground cover, as well as emergent aquatic vegetation (*e.g.*, cattails, bulrushes) to reduce flow and wave energy, thereby reducing erosion of shorelines; maintaining the roots of shrubby vegetation such as willows, red-osier dogwood, and hardhack to stabilize banks and prevent bank erosion; avoiding filling or draining permanent or seasonally wet areas; buffering wetlands by 150 m in undeveloped areas, 100 m in rural areas, and 30 m in urban areas (BC MOE 2012a). • The goal of *Management Plan for Peale's Peregrine Falcon (Falco peregrines pealei) in BC* is to maintain the population at a minimum of 100 occupied aeries and to slowly increase the population to numbers that are closer to historical numbers found in the early twentieth century (Cooper 2007). This goal will be achieved through four objectives including: managing the subspecies in order to maintain a well-distributed minimum population of 100 occupied aeries throughout the current range in coastal BC; marinating habitat quality in order to promote and overall mean annual fledging rate of at least 1.5 young per breeding pair, maintaining colonial-nesting seabird populations at current or higher levels; and monitoring organochlorine pesticide contaminants in Peale's peregrine falcons (Cooper 2007). • Environment Canada recommends activities maintain a 100 m setback from the high water mark of wetlands or waterbodies containing a horned grebe nest from April 1 to August 31 (Environment Canada 2011a). In Alberta, a 500 m setback is recommended from April 15 to July 31 for horned grebe nests (Government of Alberta 2013a). Breeding horned grebe were detected along the Edmonton to Hinton Segment during field surveys in 2013 (Wildlife Technical Report of Volume 5C). • Context for bald eagle, black-throated green warbler, Canada warbler, Cape May warbler, common nighthawk, great blue heron, olive-sided flycatcher, rusty blackbird, short-eared owl. spotted owl, and western screech-owl are provided below. • Table 7.2.10-10 provides a summary of the predicted change in effective riparian and wetland bird habitat as a result of the Project.
Wood warblers	• Wood warblers are a group of passerine birds of the family Parulidae. The wood warblers indicator includes species with special conservation status and common species. Habitat models were developed specifically for Cape May warbler and black-throated green warbler, which occupy habitats along the Edmonton to Hinton Segment that may be especially sensitive to anthropogenic disturbances. Some common species included in the wood warblers indicator community are American redstart, blackpoll warbler, Connecticut warbler, MacGillivray's warbler, ovenbird and Wilson's warbler. The indicator community includes the following species of conservation concern (AESRD 2012a, ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - black-throated green warbler (Sensitive in Alberta; Special Concern by Alberta's ESCC); - Cape May warbler (Sensitive in Alberta; In Process [previously Special Concern] by Alberta's ESCC); and - Canada Warbler (Threatened under Schedule 1 of *SARA* and by COSEWIC; Sensitive in Alberta). • The population of black-throated green warblers appears to be stable to slightly increasing across Canada, but within Alberta, observations of the species have declined (Environment Canada 2013h). Populations of Cape May warbler appear to be stable in Canada, with slight increases seen in Alberta (Environment Canada 2013h). Breeding Bird Survey data indicate a steady population decrease for Canada warbler from about 1970 to the present, with an overall loss of 70% of the population during that period (Environment Canada 2013h). • Warblers are present in Alberta from late May until late summer (August/September) (Campbell *et al.* 1990a). • Black-throated green warblers, Canada warblers and common yellowthroats primarily eat insects, including flies, spiders, caterpillars, beetles and bugs (BC MWLAP 2004b, COSEWIC 2008b). Berries and seeds are also foraged. The Cape May warbler is a spruce budworm specialist, foraging in the upper forest canopy (Morse 1978). • The species in the wood warblers indicator group are typically associated with spruce forests (Boreal Avian Modelling Project 2013). Nests are commonly built in coniferous trees or coarse woody debris, in stands with a well-developed understory that provides foraging habitat (Cooper *et al.* 1997a,b, Morse and Poole 2005, Norton 1999, 2001). Black-throated green warblers and Cape May warblers are generally associated with mature forest, while Canada warbler is found in a variety of stand ages, including shrubby riparian areas (Cooper *et al.* 1997a,b, COSEWIC 2008b, Norton 2001).

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Wood warblers (cont'd)	• Black-throated green warblers are found at highest densities in mixedwood forest with some white spruce, although pure white spruce stands and lowland forests are sometimes used (Norton 1999). Cape May warblers are found at their highest densities in pure white spruce stands, with mixed wood stands being used at lower densities. Cape May warblers rarely use lowland forest or deciduous forest (Norton 2001). Cape May warblers are rarely found in disturbed sites (Norton 2001). • Wood warblers are largely insectivorous and therefore experience population fluctuations in response to insect outbreaks (*e.g.*, spruce budworm) (Cooper *et al.* 1997a,b, COSEWIC 2008b, Norton 2001). • Habitat loss and fragmentation resulting from logging, industrial developments and the energy sector are believed to be among the most important limiting factors for wood warbler populations in Alberta (Norton 1999, 2001). • No specific management or recovery plans are available for these species in Alberta; however, habitat retention and fragmentation reduction guidelines are part of some forest management plans (Norton 1999, 2001). • Environment Canada recommends the following setback distance for disturbance activities in proximity to Canada warbler nests: from May 1 to July 31, 300 m setback from active nests for high disturbance activities 150 m for medium disturbance activities and 0-50 m for low disturbance activities (Environment Canada 2011a). • Table 7.2.10-10 provides a summary of the predicted change in effective wood warbler habitat as a result of the Project.
Short-eared owl	• Short-eared owl is listed as Special Concern on Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c), are Blue-listed in BC and have a Conservation Framework Priority rating of 2 (BC CDC 2013), and are listed as May Be at Risk in Alberta (ASRD 2011b). • Short-eared owls are not adequately sampled by regular bird surveys, but the Breeding Bird Surveys (1970-2011) captures the wide population fluctuations characteristic of this species. Most recently, short-eared owls appear to be in a phase of abundance in Alberta (Environment Canada 2013h); however, national trends indicate an overall decline since 1970 (Environment Canada 2013h). In BC, there is inadequate data for a population estimate, however, the population appears to have declined steadily in both breeding and overwintering areas since 1960 (Campbell *et al*. 1990 as cited in BC MWLAP 2004b). • Short-eared owls are nomadic and their distribution and abundance is tied to that of small rodents (BC MWLAP 2004b). • Breeding season of short-eared owls in western Canada typically extends from March to June. In some cases, owls may re-nest if the first clutch is lost, which can extend the breeding period into July (COSEWIC 2008c). Nests are located on the ground in a shallow scrape and are generally in dry areas (Holt and Leasure 1993). Nest sites in BC tend to be located in shrubby, grassy fields adjacent to agricultural areas; use of airport fields, marshes, rangeland, sagebrush plains, bogs, and hayfields has also been documented (Campbell *et al*. 1990b, COSEWIC 2008c). Short-eared owls prefer densely vegetated grasslands, and grazed areas are avoided due to increases in nest predation at these sites (Fondell and Ball 2004). In Alberta, short-eared owls have frequently been found nesting in active cropland with grain stubble. Although these sites may be attractive for nesting, fledging success may be very low (COSEWIC 2008c, Houston 1997). In addition to using agricultural fields and grasslands, young reforested areas (<10 year old) also provide attractive nesting cover (Shaw 1995). • Short-eared owls are sensitive to disturbance, especially during the nesting period, and females have been reported to abandon nests after being flushed and harassed at their nest site (Leasure and Holt 1991). • The primary threat to the short-eared owl is loss of nesting habitat due to rapid urbanization, industrialization, intensive agriculture and human disturbance. Fragmentation of habitats may cause fluctuations in the population of their rodent prey base (COSEWIC 2008c, Demarchi *et al*. 2005). • The Identified Wildlife Species Account for the short-eared owl recommends establishment of WHAs around known breeding areas, minimizing human and livestock disturbance to active winter roosts and nest sites, and maintaining important structural features, such as mid-height to tall grasses with some low shrub cover for nesting (BC MWLAP 2004b). The proposed pipeline corridor does not encounter any WHAs for short-eared owl. • The *Best Management Practices for Raptor Conservation in BC* recommend: retention of undisturbed grasslands, old fields, pastures and natural forest openings; avoidance of mowing of fields during the nesting season; and minimizing disturbance and access to potential nesting areas (Demarchi *et al*. 2005). • The *Guidelines for Raptor Conservation* in BC recommend a 500 m buffer (in undeveloped areas), a 200 m buffer (in rural areas), or an approximately 50 m buffer (in urban areas) around raptor nests, with an additional 100 m quiet buffer during nesting season (BC MOE 2013e). • In Alberta, a 100 m setback is recommended from April 1 to July 15 for short-eared owl nests (Government of Alberta 2013a). • There is no recovery plan or strategy for short-eared owl (BC MOE 2013f, Environment Canada 2013c). • Table 7.2.10-10 provides a summary of the predicted change in effective short-eared owl habitat as a result of the Project.
Rusty blackbird	• Rusty blackbird is listed as Special Concern under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c), are Blue-listed in BC and have a Conservation Framework Priority rating of 2 (BC CDC 2013), and are listed as Sensitive in Alberta (ASRD 2011b). • The rusty blackbird is migratory and is present in Canada from early April to early October (COSEWIC 2006e).The population of rusty blackbird in Canada, which is about 70% of the global population, is estimated at 110,400 to 1.4 million individuals (COSEWIC 2006e). The estimates vary greatly, but include data from Breeding Birds Surveys and the Canadian Migration Monitoring Program. Long-term trend analyses based on Christmas Bird Counts (in the rusty blackbird winter range in the US) indicate that the rusty blackbird population has declined substantially over the last 40 years (COSEWIC 2006e). • Rusty blackbird habitat includes forest wetlands, such as slow moving streams, peat bogs, sedge meadows, marshes, swamps, beaver ponds and pasture edges. In winter, it occurs primarily in damp woodlands and cultivated fields. Females build the nests, which are typically placed in thickets of small conifers, deciduous shrubs or in dead trees, usually over or close to water (COSEWIC 2006e).

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Rusty blackbird (cont'd)	• Rusty blackbirds are highly specialized and, therefore, may have limited ability to adapt to even slight changes in habitat (Smithsonian 2012). Although the reasons for the species' decline are unclear and attributed largely to habitat degradation in wintering habitats, alteration or loss of wetlands in the forest breeding habitat is suspected to be a contributing factor (COSEWIC 2006e, Greenberg and Matsuoka 2010, Smithsonian 2012). Competition with dominant species such as red-winged blackbird, disease, pest control (in the wintering grounds in the US), and increased predation and inter-specific competition in fragmented habitats have also been suggested contributing factors for rusty blackbird declines (COSEWIC 2006e, Greenberg and Matsuoka 2010). • Environment Canada recommends the following species specific setback for rusty blackbird nests: from May 1 to July 31, a 300 m setback for high disturbance activities, a 150 m setback for medium disturbance activities and 0-50 m for low disturbance activities (Environment Canada 2011a). • There is no Identified Wildlife Species Account, recovery plan or strategy for rusty blackbird (BC MOE 2013f, BC MWLAP 2004b, Environment Canada 2013c). • Table 7.2.10-10 provides a summary of the predicted change in effective rusty blackbird habitat as a result of the Project.
Flammulated owl	• Flammulated owl is listed as Special Concern under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c), is Blue-listed in BC and has a Conservation Framework Priority rating of 2 (BC CDC 2013). • Population estimates and distribution are uncertain. A recent population estimate (2001) 1,200-2,000 owls across a range of 113,000 km² in BC (van Woundenberg 2001 as cited in COSEWIC 2010b). Local estimates of individuals include 337 owls were counted in the Kamloops Forest District (Booth and Merkens 1998); 26 owls in 1995 and 40 owls in 1996 at Wheeler Mountain (van Woudenberg and Christie 1997); and 24 owls in the Heffley Creek area in 2007 (Iredale and Ferguson 2007). Estimates of breeding pairs in 1999 were 100 pairs in the Okanagan Valley, 100-200 pairs in the Merritt Forest District, and >200 pairs in the Kamloops Forest District (van Woudenberg 1999). • There is no information regarding population trends for the province. Suitable habitat is declining due to harvesting of old-growth forest and firewood cutting, which may limit the population of flammulated owls (BC MWLAP 2004b). • Flammulated owls are associated with open ponderosa pine forest or Douglas-fir forest. Mature or old forest is important habitat for nesting, roosting and foraging. They are a secondary cavity nester and use either natural cavities or cavities excavated by pileated woodpeckers or northern flickers (Campbell *et al.* 1990b). Ponderosa pine appears to be selected over Douglas-fir for nesting, likely due to greater use by pileated woodpeckers and northern flickers (BC MWLAP 2004b). • Flammulated owls are insectivorous. Foraging occurs in flight and prey is either taken in tall grass or shrubs in forest openings or from the forest canopy (BC MWLAP 2004b). Openings used for foraging can be natural (*e.g.*, blowdown) or result from forest harvesting (van Woudenberg 1992), however, openings must be small (<1 ha) and adjacent to forest cover for security (BC MWLAP 2004b). Foraging generally occurs within 300 m of the nest (BC MWLAP 2004b). • Flammulated owls are present in BC during the breeding season from May to September (BC MWLAP 2004b). They will reuse the same tree or group of trees in subsequent years, but generally occupy different cavities. • Flammulated owls are habitat specialists, and the loss or degradation of old heterogeneous stands of Douglas-fir and ponderosa pine has potential to limit populations in BC. Suitable habitat has decreased substantially from historic levels as the result of forest harvesting, fire suppression, and, more recently, from mountain pine beetle infestation (COSEWIC 2010b). • The British Columbia Provincial Flammulated Owl Working Group (PFOWG) established the *Management Plan for the Flammulated Owl (Otus flammeolus) in British Columbia* in 2011 (PFOWG 2011). The goal of this management plan is to maintain stable or increasing populations of flammulated owl distributed throughout the species' present range. This goal will be achieved through five management objectives: 1) identify population, habitat, and distribution targets required to maintain viable populations; 2) initiate protection and/or management of priority breeding habitats; 3) investigate knowledge gaps related to cumulative impacts of medium impact, extreme severity, or unknown threats (*e.g.*, mountain pine beetle, fire and fire suppression, timber harvest); 4) investigate knowledge gaps related to range management; and 5) establish and implement a monitoring program for flammulated owl populations and habitat. • The Identified Wildlife Species Account (BC MWLAP 2004b) recommends four general measures for management of flammulated owls in BC: establish WHAs that area appropriately sized and structured; minimize disturbance during the breeding season (June 1 to August 31); maintain adequate foraging habitat for productivity; and ensure security cover from predators for both foraging adults and fledglings. The proposed pipeline corridor does not encounter any WHAs for flammulated owl. • Recommendations from the BC *Develop with Care Guidelines* for flammulated owl include protection of nesting, foraging and perching habitats and features, and establishment of buffers around nesting habitats (500 m in undeveloped areas, 200 m in rural areas, approximately 50 m in urban habitats, and an additional "quiet" buffer of 100 m during breeding season) (BC MOE 2012a). • The goal of the *Management Plan for the Flammulated Owl (Otus flammeolus) in Canada* (Environment Canada 2013j) is to maintain stable or increasing populations of flammulated owl throughout the species' range in BC. Specifically, the objectives of the plan are to quantify population, habitat and distribution targets required to maintain viable populations, protect and/or manage of priority breeding habitat, address knowledge gaps with regards to threats and management, and institute a monitoring program of owls and their habitat. • Table 7.2.10-10 provides a summary of the predicted change in effective flammulated owl habitat as a result of the Project.

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Lewis's woodpecker	• Lewis's woodpecker is listed as Threatened under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c), is Red-listed in BC and has a Conservation Framework Priority rating of 2 (BC CDC 2013). • The proposed pipeline corridor crosses early candidate critical habitat for Lewis's woodpecker, which is in the early stages of internal review (Environment Canada 2013d). The Wildlife Technical Report in Volume 5C provides additional information regarding candidate critical habitats. • The BC population was estimated at 600 breeding pairs in 1990 and 630-920 adults in 2007 (BC MWLAP 2004b, COSEWIC 2010c). The current population estimate is 315-460 pairs (Environment Canada 2011b). Lewis's woodpecker populations have declined in total numbers, extent of occurrence and area of occupancy. Population trends in the East Kootenay Trench show an estimated 22% decline in this species from 1997 to 2007 (COSEWIC 2010c). Breeding Bird Surveys show a general decline in sightings of this species in BC (Environment Canada 2013h). • Lewis's woodpeckers typically nest in open areas with low tree densities, and are generally found in three habitat types: open forest or shrub-steppe/grassland with scattered trees (especially ponderosa pine); riparian cottonwood forests adjacent to open areas; and burns (COSEWIC 2010c, Vierling *et al.* 2013). • Lewis's woodpeckers nest in the cavities of trees, especially within ponderosa pine, black cottonwood and Douglas-fir (BC MWLAP 2004b). Western larch, trembling aspen and paper birch may also be suitable for nesting, and utility poles have been used as nest sites when close to good foraging grounds (Cooper and Beauchesne 2000). Lewis's woodpeckers are weak cavity excavators; they can excavate their own nest cavity, but often use holes excavated by other woodpeckers or natural cavities (Cooper and Beauchesne 2000). Large diameter, decaying snags are often ideal for nest cavity excavation by Lewis's Woodpecker, and are important components of breeding habitat (BC MWLAP 2004b). The same cavity is often occupied in consecutive years (COSEWIC 2010c). • The Lewis's woodpecker has a wide ranging diet that changes throughout the year to take advantage of seasonally abundant food sources. A well developed ground cover or understory layer providing suitable foraging opportunities (insects, berries) is an important component of habitat suitability. Large open areas are required to provide enough space and visibility for aerial pursuit of flying insects (BC MWLAP 2004b). • Lewis's woodpeckers are migrants, present in BC from May to September (BC MWLAP 2004b). • The loss or degradation of suitable breeding habitat is believed to be a limiting factor for Lewis's Woodpecker in BC (COSEWIC 2010c). Habitat has been substantially reduced as a result of fire suppression (resulting in the growth of dense forest stands), removal of snags for safety reasons, intensifying agricultural practices, over grazing, urbanization, commercial forestry (especially the selective removal of ponderosa pine and the replanting of dense stands), harvesting trees for firewood, and industrial development (COSEWIC 2010c, Vierling *et al.* 2013). • In their 1998 status report, Cooper *et al.* (1998) recommend the following measures for management of Lewis's woodpecker in BC: management of ponderosa pine forests and riparian stands of black cottonwood to maintain an adequate abundance of soft snags; habitat enhancement including girdling of live, mature ponderosa pines or black cottonwoods to produce snags suitable for nesting, and managed burns to create open habitats; public education to raise awareness of the value of wildlife and wildlife habitat; habitat acquisition including purchasing lands to protect habitat; and a wildlife tree sign program. • The *Ecological Area Assessment for the Lac du Bois Grasslands Protected Area* identifies habitat potential for Lewis's woodpecker and recommends that large standing snags should be retained as wildlife trees for Lewis's woodpecker and other cavity nesting birds (Grasslands Conservation Council of British Columbia 2009). • The Identified Wildlife Species Account (BC MWLAP 2004b) recommends the following measures to protect and manage Lewis's woodpecker: establish WHAs to maintain suitable nesting habitat for multiple pairs; provide an adequate supply of large diameter live and dead wildlife trees suitable for foraging and nesting; maintain an open canopy; maintain the integrity of nesting habitat; and maintain adequate shrub cover. • The objective of the *Management Plan for Lewis's Woodpecker (Melanerpes lewis) in Canada* (Environment Canada 2011b) is to increase the breeding population of Lewis's Woodpeckers across their current range in Canada to approximately 600 pairs by 2040. The plan includes six strategies and conservation measures: secure breeding habitat around known nests; develop and implement strategies that will maintain the nests; manage Lewis's Woodpecker nest trees and foraging habitats on unsecured crown lands, private land, and Indian Reserve lands following best management practices; conserve migration stopover and overwintering habitat; assess the threats to Lewis's woodpecker; and conduct research and monitoring. The Management Plan recommends the following best management practices for forest management: maintain open forests (< 25% canopy closure) dominated by ponderosa pine, black cottonwood or Douglas-fir with some large snags and recruitment trees; retention of clusters of trees rather than uniformly distributed trees in salvaged or harvested stands; and retention of naturally vegetated linkages between riparian areas, open forest, and reserve areas. Habitat restoration best management practices include removal of conifer regeneration and encroachment, and creating nest trees and snags. Range use best management practices include management of the distribution and intensity of livestock grazing in suitable habitat and near known nests. Disturbance should avoid frequent or prolonged disturbance at nest sites during the breeding season (May to August) (Environment Canada 2011b). There is currently no federal recovery strategy for Lewis' woodpecker. • Table 7.2.10-10 provides a summary of the predicted change in effective Lewis's woodpecker habitat as a result of the Project.

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Williamson's sapsucker	• Williamson's sapsucker is listed as Endangered on Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c) and is Blue-listed in BC (BC CDC 2013). The *thyroideus* ssp. occurs within the Wildlife LSA and RSA. • The proposed pipeline corridor intersects proposed critical habitat for Williamson's sapsucker (Environment Canada 2013d). The proposed recovery strategy for Williamson's sapsucker has not yet been posted on the Species at Risk Public Registry for public review and comment. The Wildlife Technical Report in Volume 5C provides additional information regarding proposed critical habitats. • Based on inventory data to 2007, the estimated Williamson's sapsucker population in BC is 460-1,000 breeding birds (BC MOE 2012b). There are no reliable trend data for the Canadian population, but in Oregon, where it has been assessed, this species has declined at an average rate of 3.3% per year from 1980 to 2003 (COSEWIC 2005). Williamson's sapsucker is considered an accidental species in Alberta. • The Williamson's sapsucker is found in mature coniferous or mixed deciduous mountain forests at mid to high elevations with large-diameter partially decaying trees as nest trees (Gyug *et al.* 2009). They are strongly associated with forests containing western larch where it occurs. They may also use spruce, Douglas-fir, lodgepole pine, ponderosa pine and trembling aspen as nest trees (BC MWLAP 2004b, Gyug *et al.* 2009). • Feeding sites may range up to 460 m from the nesting sites, but are typically less than 100 m from the nest tree (COSEWIC 2005; Gyug *et al.* 2009). Forage trees are typically live mature conifers (*e.g.*, Douglas-fir, ponderosa pine, western larch, lodgepole pine), but also include snags and aspen that contain abundant forage (especially ants) (Gyug *et al.* 2009, Gyug *et al.* 2012). • A migratory species, the Williamson's sapsucker is present in BC from April to July (BC MWLAP 2004b). • Habitat with suitable nest sites is believed to be the primary limiting factor for Williamson's sapsucker in Canada (COSEWIC 2005, Gyug *et al.* 2012). Large, partially decaying trees are necessary and they do not occupy isolated trees within openings or small remnant patches of aspen within non-forested habitat (COSEWIC 2005, Gyug *et al.* 2012). Nest productivity (*i.e.*, number fledged per nest) is reduced in open stands with low tree density; in particular, when tree density goes below 85 trees/ha in the breeding territory (Gyug *et al.* 2010). • Williamson's sapsuckers are generally tolerant of disturbance and often forage near or within forest openings (Gyug *et al.* 2012). The primary impact of human activities is likely through direct habitat loss and the removal of large dead or decaying trees. However, it was assumed that high levels of noise would reduce habitat quality by impeding intra-specific communication or predator detection (Gyug *et al.* 2012). • Loss of old forest as a result of short-rotation forestry and industrial development is a concern for management of Willamson's sapsucker habitat (COSEWIC 2005). • The Identified Wildlife Species Account for Williamson's sapsucker identifies the primary threats to Williamson's sapsucker as a small population size making the species vulnerable to extirpation, and habitat loss due to logging of mature or old western larch and Douglas-fir stands. The conservation and management goals recommended include maintenance of suitable nesting trees during industrial and forestry activities, and establishment of WHAs that area appropriately sized and structured (BC MWLAP 2004b). • The *Recovery Plan for the Williamson's Sapsucker* (Sphyrapicus thyroideus) *on Crown Lands in British Columbia* (BC MOE 2012b) was developed with the goal to ensure the persistence of Williamson's sapsucker in Canada by maintaining the population at or above the current abundance, distribution, and area of occupancy. To achieve this goal, habitat attributes will need to be identified and locations of suitable habitat described to facilitate management and mitigate habitat threats (BC MOE 2012b). • Table 7.2.10-10 provides a summary of the predicted change in effective Williamson's sapsucker habitat as a result of the Project.

Western screech-owl	• Separate habitat models were completed for the coastal and interior subspecies of western screech-owl (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C), however, the two subspecies are assessed as a single indicator (ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c):
	  - *Megascops kennicotti kennicotti* (Special Concern under Schedule 1 of *SARA*; Threatened by COSEWIC; Blue-listed in BC; Conservation Framework Priority 1); and
	  - *M.k. macfarlanei* (Endangered under Schedule 1 of *SARA*; Threatened by COSEWIC; Red-listed in BC; Conservation Framework Priority 1).
	• It is estimated that 50-200 owls (*macfarlanei* ssp.) inhabit a range of 22,000 km² in the interior region of BC, mostly within the Okanagan and lower Similkameen valleys (COSEWIC 2002c, western screech-owl, *macfarlanei* ssp. Recovery Team 2008). The provincial population estimate for this subspecies is 350-500 individuals (COSEWIC 2012e).
	• There are approximately 3,000-10,000 owls (*kennicotti* ssp.) inhabiting the 50,000 km² area along the southern coast of BC and about 10 breeding pairs in the Greater Vancouver area (COSEWIC 2002c). More recent population surveys for the *kennicotti* ssp. estimate 1,500 to 3,000 individuals in BC (COSEWIC 2012e).
	• Data from the BC-Yukon Nocturnal Owl Survey on the central and south coast show a steep decline in western screech-owl detections between 2000 and 2009 (COSEWIC 2012e). Christmas Bird Count data from the south coast of BC similarly show a substantial population decline (COSEWIC 2012e).
	• Western screech-owls are non-migratory, territorial birds found in woodland habitats, generally at low elevation and near riparian habitat (BC MWLAP 2004b, Campbell *et al.* 1990b). Nests are located in secondary or natural tree cavities; nest boxes are sometimes used where provided (COSEWIC 2012e). Egg-laying occurs between March and May; the young stay in the nest as late as August before dispersing (BC MWLAP 2004b).

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Western screech-owl (cont'd)	• Western screech-owls prefer mature mixedwood or deciduous forests in close proximity to riparian habitat, likely due to the presence of large deciduous trees in these areas. Black cottonwood, trembling aspen and water birch are preferred species for nesting, due to a propensity for natural cavities. Coniferous trees are also used, especially when there are nesting cavities previously made by pileated woodpecker or northern flicker (Cannings and Davis 2007). • As a secondary cavity nester, the availability of suitable nesting trees is a limiting factor for nesting habitat since each breeding pair requires a minimum of two nest cavities (BC MWLAP 2004b, Cannings and Davis 2007). • Habitat loss through forestry activities (*i.e.*, timber harvesting and the removal of dead trees and snags that serve as potential nest cavity trees) is the primary threat to both subspecies of western screech-owl (BC MOE 2013h, COSEWIC 2012e). In the southern interior of BC, an estimated 50% of its habitat has already been lost and the majority of the remainder is degraded (BC MWLAP 2004b). • Additional threats to western screech-owl (*kennicotti* ssp.), especially on the southern part of Vancouver Island and the lower mainland, include urbanization and increased predation from newly established populations of barred owls (BC MOE 2013h, COSEWIC 2012e). • There is no Identified Wildlife Species Account available for western screech-owl (*kennicotti* ssp.) (BC MWLAP 2004b). The Identified Wildlife Species Account for western screech-owl (*macfarlanei* ssp.) recommends protecting habitat (BC MWLAP 2004b). The proposed pipeline corridor does not encounter any WHAs for western screech-owl. • The *Recovery Plan for the Western Screech-owl, kennicottii ssp. (Megascops kennicottii kennicottii) in British Columbia* (BC MOE 2013h) identifies the protection of breeding habitat, establishment and implementation of a monitoring program to assess trends in occupancy and habitat availability across the subspecies range, and assessment and mitigation of current threats as primary objectives. • The western screech-owl, *macfarlanei* ssp. Recovery Team was established with the goal of maintaining a viable, well-distributed population in secure habitat across its known range (Western Screech Owl, *macfarlanei* subspecies Recovery Team 2008). The objectives of the Recovery Team are to secure a minimum of 400 ha of nesting habitat and adjacent foraging habitat at priority sites and to address knowledge gaps of population size, distribution, demographics, viability, habitat requirements and distribution, genetics, and clarification of potential threats. • Recommendations from the BC *Develop with Care Guidelines* for western screech-owl include: protect nest sites with a buffer of at least 1.5 tree lengths in urban areas and 200 m in rural areas plus an additional 200 m buffer during the breeding season (March 15 to August 31); retain existing habitats and features; restore availability of nest cavities by replacing any that were damaged or lost with suitable nest boxes; and protect roost and perch sites (BC MOE 2012a). • The BC *Guidelines for Raptor Conservation* recommend a 500 m buffer around western screech-owl nests in undeveloped areas, and an additional 'quiet' 100 m buffer (*i.e.*, a total of 600 m) during the breeding season (February 17 to August 25) (BC MOE 2013e). • Table 7.2.10-10 provides a summary of the predicted change in effective western screech-owl habitat as a result of the Project.
Great blue heron	• The coastal and interior subspecies of great blue heron are included in this indicator, which is assessed at the species level. The status designations of the subspecies are (BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - *Ardea herodias fannini* (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 1); and - *A. h. herodias* (Blue-listed in BC; Conservation Framework Priority 2; Sensitive in Alberta). • Population size has been difficult to estimate for great blue heron since colonies are not stable entities and are difficult to track in a standardized fashion (Gebauer and Moul 2001). The *fannini* ssp. in BC is currently estimated at 3,626 breeding adults, with an estimated 3,326 adults breeding in the Strait of Georgia and 300 breeding elsewhere on the coast (Gebauer and Moul 2001). The population size of the *herodias* ssp. in BC is not known, but probably ranges between 300 and 700 individuals (Gebauer and Moul 2001). • There is conflicting information regarding population trends for great blue heron in BC. The Christmas Bird Count shows declines over the last three generations, while the Coastal Waterbird Survey shows a five-year increase. Colony surveys suggest that there have been substantial declines in productivity and success since 1970 (COSEWIC 2008d). • Great blue herons require different habitats for nesting and for foraging. Foraging habitat must be within 10 km of nesting habitat. Important foraging habitats include estuaries, eelgrass beds, tidal flats, freshwater marshes and other wetlands, old fields, river and lake edges, and flooded fields (BC MOE 2012a, BC MWLAP 2004b). Inland fields are considered an important foraging habitat for both adults and juveniles in the lower Fraser Valley and on southern Vancouver Island (Gebauer and Moul 2001). Nesting habitats include contiguous forest, fragmented forest, and solitary trees The most common tree species used for breeding on the coast are red alder, black cottonwood, bigleaf maple, lodgepole pine, Sitka spruce and Douglas-fir (Gebauer and Moul 2001). In the southeastern interior, black cottonwood comprises 54% of nest trees with coniferous species (Douglas-fir, western white pine, hybrid white spruce , ponderosa pine, western redcedar and western hemlock) accounting for the remaining 46% (BC MWLAP 2004b). • Great blue herons are sensitive to disturbance, which can result in nest and/or colony abandonment (BC MWLAP 2004b, COSEWIC 2008d). • Direct threats to great blue heron populations in BC include human disturbance, mortality from predators (*e.g.*, bald eagles) and humans, limited food supply, and stochastic weather events, including high rainfall events and wind storms (BC MWLAP 2004b).

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Great blue heron (cont'd)	• The Status of the Great Blue Heron in British Columbia report recommends the following measures to manage and protect the populations in BC: buffer zones; barriers to disturbance such as fences, ditches, other watercourses, and dense forests; seasonal windows of activity (activities that may negatively affect herons should be avoided between mid-February and early August on the coast and between March and August in the interior); establishment of protected areas; timber harvest plans to protect future heron nesting sites; urban planning to include suitable habitats in designs for parks, greenbelts, and subdivisions; agricultural planning to include treed hedgerows for nesting and roosting adjacent to winter foraging fields and drainage ditches; and habitat enhancement (Gebauer and Moul 2001). • The Identified Wildlife Species Account for great blue heron in BC identifies the following measures for management and recovery: establishment of WHAs to protect nesting sites; minimization of disturbance during the breeding season (February 15 to August 31) and between November 1 and March 31 for colonies that occupy areas year round; and maintenance of important structural elements for nesting and foraging (*i.e.*, suitable nest trees, non-fragmented forest around nest trees, wetland characteristics for foraging if applicable, roost trees, and ground barriers to exclude mammalian predators) (BC MWLAP 2004b). • Recommendations from the BC *Develop with Care Guidelines* for great blue herons include: protection of potential heron nesting habitats that occur within 3–4 km of known foraging areas; establishment of buffers around nesting areas (300 m in undeveloped areas, 200 m in rural areas, and 60 m in urban areas) including an additional "quiet" buffer of 200 m during breeding season; and timing of construction in the Least Risk Window of September 1 to February 15 (new disturbances should be avoided between February 15 and August 31 when herons are nesting) (BC MOE 2012a). • In Alberta, it is recommended that activities not occur within 1,000 m of great blue heron nesting colony (Government of Alberta 2013a). • Table 7.2.10-10 provides a summary of the predicted change in effective great blue heron habitat as a result of the Project.
Spotted owl	• Spotted owl is Endangered under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c), is Red-listed in BC and has a Conservation Framework Priority rating of 2 (BC CDC 2013). • The proposed pipeline corridor crosses the Sowaqua Spotted Owl WHA (2-498) for spotted owl, which is identified as a Long-term Owl Habitat Area (LTOHA). • The population of spotted owls in BC was estimated to be about 500 pairs prior to European settlement (Blackburn *et al.* 2002), and has been steadily declining from less than 30 pairs (60 birds) in 2002 to 19 birds at 14 sites in 2007 (Blackburn and Godwin 2004a, COSEWIC 2008e, Hausleitner 2006, Hobbs 2005). • The spotted owl is associated with a variety of forest types but is generally found in mature to old growth forests dominated by coniferous tree species (COSEWIC 2008e). The requirements for all life requisites (foraging, roosting and nesting) are met in these habitats. • Habitat requirements include structural diversity (structural deformities, snags, broken tops of trees), multiple canopy layers with open spaces for flying, moderate to high canopy cover, and large amounts of large coarse woody debris on the forest floor (Blackburn and Godwin 2004a). High suitability habitat is more likely to be used for nesting, while low suitability habitat may only be used for foraging or roosting. • Spotted owls require very specific structural habitat features for nesting. The spotted owl does not create its own nesting cavities or platforms but uses cavities excavated by other birds (*e.g.* pileated woodpecker), platforms constructed by other birds (*e.g.*, northern goshawk), natural cavities, or accumulations of debris that form nesting platforms (Blackburn and Godwin 2004a). Spotted owl nests average approximately 50 cm in diameter; therefore, large diameter trees with large branches, snags, or cavities are required. These trees are generally found in mature and old growth forests with a mean tree age >140 years. • Home range size varies throughout the year, from a small area surrounding the nest in breeding season to several thousand hectares in the winter (Forsman *et al.* 1984). • The spotted owl is vulnerable to extirpation in BC due to its small population size and low densities. The primary threats facing the spotted owl are habitat loss and fragmentation, and increased competition with the barred owl, likely as the result of habitat fragmentation (Blackburn and Godwin 2004b, Dugger *et al.* 2011, Kelly *et al.* 2003). The small population size combined with habitat fragmentation may limit the connectivity of the spotted owl population in BC by reducing recruitment of dispersing juvenile owls, increasing the number of sites occupied by a single owl (rather than pairs), and increasing the distance between breeding pairs (COSEWIC 2008e). The amount and distribution of suitable habitat can further affect reproductive success since spotted owls show site fidelity to breeding habitats (COSEWIC 2008e). • The reproductive success of northern spotted owls has been shown to decrease within 100 m of noisy roads in northern California (Hayward *et al.* 2011). Nesting success did not decrease near quiet roads in northern California; however, northern spotted owls are known to avoid nesting within 100 m for a forest edge (Johnson 1993) and California spotted owls show a positive selection for the amount of interior forest habitat (>100 m from an edge) (Chatfield 2005). Due to competition with barred owls, a negative response to forest edge is likely to occur in BC. • The goal of the *Spotted Owl Management Plan* (1997) was to achieve a reasonable level of probability that populations would stabilize, and possibly improve over the long-term, without substantial short-term impacts on timber supply or forest industry employment (Spotted Owl Management Inter-Agency Team 1997). As a part of the Spotted Owl Management Plan, 21 special resource management zones were established. In the 5 years following this document, the population of spotted owls continued to decrease dramatically. In 2004, additional habitat protection was afforded to known spotted owl occurrences in the form of WHAs (Spotted Owl Best Management Practices Working Group 2009). • The goal of the *Recovery Strategy for the Northern Spotted Owl (Strix occidentalis caurina) in British Columbia* is to down-list the spotted owl from Endangered status by establishing a stable or increasing, self-sustaining population distributed throughout the species' natural range (Chutter *et al.* 2004). This recovery strategy was reviewed and adopted by the BC provincial government in 2006.

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Spotted owl (cont'd)	• Following the recovery strategy, the Spotted Owl Population Enhancement Team (SOPET) was formed in 2006. The team produced a Five-year Action Plan, with a primary goal of facilitating the recovery of the spotted owl population in BC through population enhancement. The plan included establishment of a captive breeding and reintroduction program for spotted owls within BC. As part of this, predator and competitor control programs were also proposed (SOPET 2007). • In 2009, the previous management plans were revisited and revised. The resultant document, *Best Management Practices for Managing Spotted Owl Habitat* (Spotted Owl Best Management Practices Working Group 2009), aims to recover and sustain the spotted owl population and protect spotted owl habitat by establishing WHAs (LTOHAs and Managed Future Habitat Areas). One LTOHA for spotted owls is intersected by the proposed pipeline corridor (WHA 2-498). The management goal in a LTOHA is to achieve 100% suitable spotted owl habitat conditions by conserving the existing spotted owl habitats and creating additional spotted owl habitats. A no-net-loss policy is in place in the LTOHAs and management recommendations include limited clearing, retention of large trees and prioritizing regeneration of vegetation and trees in clearings (Spotted Owl Best Management Practices Working Group 2009). • Table 7.2.10-10 provides a summary of the predicted change in effective spotted owl habitat as a result of the Project.
Bald eagle	• Bald eagle is Yellow-listed in BC (BC CDC 2013) and is listed as Sensitive in Alberta (ASRD 2011b). The species is designated Not at Risk by COSEWIC (COSEWIC 2007). • Aboriginal participants reported that the bald eagle is a species of high cultural value. The bald eagle represents many things, including luck, womanhood, wisdom and protection; and bald eagle bones and feathers have many ceremonial uses. Primary concerns identified during Aboriginal participation in field studies for the Project were disturbance or destruction of bald eagles' nests during construction (Wildlife Technical Report of Volume 5C). • The global population of bald eagles was estimated to be 70,500 birds in 1980. Of this total, approximately 30,000 bald eagles occurred in Canada with 28,500 in BC (Gerrard 1983 cited in Blood and Anweiler 1994). Since the 1970s, observations of this species have been increasing steadily throughout its Canadian range (Environment Canada 2013h). • In the Pacific Northwest, the population of bald eagles increased four-fold in the last 30 years (Elliott *et al.* 2011). • The bald eagle nests earlier in the year than other birds in the same area and it tends to be territorial during the breeding season (Blood and Anweiler 1994). The nesting densities of bald eagles vary by region and are generally highest where food abundance is highest (Blood and Anweiler 1994). • In BC, most of bald eagle nests have been found in old growth ponderosa pine, Douglas-fir, Sitka spruce and western hemlock trees within 1.6 km of a large waterbody (Blood and Anweiler 1994). Nests are often used for several years and there may be alternate nest sites within a single territory. Nest site selection appears to be dependent on structural characteristics of the tree (*e.g.*, tallest tree in area, clear flight path to nearby water, view of surrounding area, proximity to food source) rather than tree species (Blood and Anweiler 1994). • The seasonal movements of the bald eagle are complex and vary by geographic region, weather, food availability, individual birds (Blood and Anweiler 1994). Some bald eagles migrate, while other populations occur year-round in BC (Blood and Anweiler 1994). • Ice-free waterbodies, including rivers, are the most important habitat requirement for bald eagles wintering in BC, and population sizes will fluctuate regionally and seasonally, based on the availability of prey. Bald eagles use the entire coastline during the winter, focusing largely on fish spawning rivers, and estuaries and mudflats with wintering waterfowl (Blood and Anweiler 1994). In addition to foraging habitat, bald eagles also require adequate perching and roosting habitat in proximity to waterbodies throughout the winter. Roosting and perching habitat includes snags, deciduous or spindly coniferous trees, pilings, log booms, or unvegetated ground. • The primary threats to bald eagles are shooting mortality, pesticide contamination, and habitat loss (Blood and Anweiler 1994). The 1994 report on the status of the bald eagle in BC identifies inventory, protection and research as necessary for bald eagle protection and management, and recommends the following measures: a province-wide nest tree inventory; protective buffering around nest trees, key forage resources, and habitats; province-wide elimination of lead shot; discontinued use of some pesticides; movement of ungulate carcasses away from road edges; modified design of power lines; reduced use of leg-hold traps and snares; increased support of rehabilitation programs; and research to fill knowledge gaps in eagle ecology, mortality and tolerance to human disturbance (Blood and Anweiler 1994). • There is no Identified Wildlife Species Account available for bald eagle (BC MWLAP 2004b). • Recommendations from the BC *Develop with Care Guidelines* for bald eagles include: management and restoration of raptor habitat and features including feeding, roosting, and perching sites; preserve good foraging sites include shorelines, estuaries, wetlands, shrubby areas, old fields, hedgerows, and riparian areas; establishment of buffers around nesting areas (200 m in undeveloped areas, 100 m in rural areas, and approximately 50 m in urban areas) including an additional "quiet" buffer of 100 m during breeding season; and timing of construction within the Least Risk Window of September 1 to December 31 (BC MOE 2012a). • The proposed pipeline corridor crosses Sensitive Raptor Range for bald eagle along the Edmonton to Hinton Segment. In Alberta, a year-round 1,000 m buffer is recommended for bald eagle nests (Government of Alberta 2013a). • Table 7.2.10-10 provides a summary of the predicted change in effective bald eagle habitat as a result of the Project.

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Common nighthawk	• Common nighthawk is listed as Threatened under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c), is Yellow-listed in BC and has a Conservation Framework Priority rating of 2 (BC CDC 2013) and is listed as Sensitive in Alberta (ASRD 2011b). • Based on Breeding Bird Surveys, the population estimate of common nighthawks in Canada is 400,000 individuals (COSEWIC 2007a). Between 1976 and 2011, this species has been declining on a national scale at an average annual rate of 3.81% (Environment Canada 2013h). In BC, the species has experienced an average annual decline of 2.52% from 1970 to 2011 in BC (Environment Canada 2013h). • Common nighthawks breed in a variety of open habitat types, including sand dunes and beaches, recent burns and logged areas, forest clearings, prairies, pastures, bogs, marshes, lakeshores, gravel roads, river banks, rock barrens and outcrops, railways, quarries, urban parks, airports, mines (COSEWIC 2007a), clear-cuts and burns (Poulin *et al.* 2011), and open ponderosa pine forests (Campbell *et al.* 1990b). Although common nighthawks may use urban areas, natural sites are preferred (Brigham 1989). • Non-vegetated sites with bare ground or rock are markedly preferred for nesting (Allen and Peters 2012, Lohnes 2010). In urban areas, gravel rooftops can provide attractive nesting habitat, although high sun exposure at these sites has been associated with nestling mortality (COSEWIC 2007a). When nesting in natural habitats, young nighthawks seek refuge from the sun and heat in nearby vegetation (Lohnes 2010). • Common nighthawks are limited by the availability of suitable nesting habitat. Habitat loss has resulted from forest fire suppression, changes to forest harvesting practices, reforestation efforts, and intensive agricultural practices. All of these changes result in fewer open areas suitable for common nighthawk nesting (COSEWIC 2007a). A general decline in insect populations due to pesticide use, particularly in urban environments, may be responsible for the decline in some common nighthawk populations (COSEWIC 2007a, Nebel *et al.* 2010, Poulin *et al.* 1996). • Environment Canada recommends the following species-specific setback for common nighthawk: from May 1 to August 31, a 200 m setback for high disturbance activities, 100 m setback for medium disturbance activities, and 0-50 m for low disturbance activities (Environment Canada 2011a). • There is no Identified Wildlife Species Account available for common nighthawk (BC MWLAP 2004b). There is currently no recovery plan or strategy for common nighthawk (BC MOE 2013f, Environment Canada 2013c). • Table 7.2.10-10 provides a summary of the predicted change in effective common nighthawk habitat as a result of the Project.
Northern goshawk	• Northern goshawk *laingi* spp., is listed as Threatened under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c) is Red-listed in BC and has a Conservation Framework Priority rating of 1 (BC CDC 2013). • It is difficult to determine population size or trends for northern goshawk as the species breeds at low densities and can be difficult to detect (Northern Goshawk Recovery Team [NGRT] 2008). The Breeding Bird Survey results are insufficient to estimate population trends for northern goshawk species (Environment Canada 2013h). Nevertheless, goshawks are believed to be declining in Canada due to the loss of mature forests which they require for nesting and foraging (Cooper and Stevens 2000). In BC, the *laingi* ssp. is believed to number <1,000 individuals (COSEWIC 2000). • Northern goshawk nest sites occur in a wide variety of forest types, including deciduous, coniferous and mixed forests. Northern goshawks require mature to old growth (>80 years old) forest (BC MFLNRO and MOE 2013, Coopers and Stevens 2000, Penteriani 2002). Preferred habitats have an open understory, which provides necessary space for foraging, flying and access to nests (Mahon 2009, Penteriani 2002, Schaffer *et al.* 1999). The home range of the northern goshawk includes nest areas (fine-scale), post fledging areas, and foraging areas (larger scale) (Reynolds *et al.* 1992). In BC, most northern goshawks are residents and overwinter close to a foraging home range, which includes the nest site (Stuart-Smith *et al.* 2012). • The primary threat facing northern goshawks is the loss of mature forest habitat for nesting and foraging (Cooper and Stevens 2000, Stuart-Smith *et al.* 2012). Loss of mature forest results in fewer suitable nesting sites and reductions in prey diversity and availability (NGRT 2008). Forest fragmentation has the potential to adversely affect northern goshawk populations as exposure to cold and rain can cause nestling mortality increases (Squires and Reynolds 1997). Dense canopy in the nest stands can maintain a mild and stable microclimate (Schaffer 1998, Schaffer *et al.* 1999). Northern goshawks may alter their behaviour to avoid forest clearings and industrial and forestry disturbances (Coopers and Stevens 2000), which potentially alters their dispersal and may lead to genetic isolation. Additional known and perceived threats include introduced species, depredation and competition, climate change, and disease (NGRT 2008). • Recommendations from the BC *Develop with Care Guidelines* for northern goshawk include: conserve habitat and habitat connectivity; minimize disturbance around known breeding territories; and protect nest sites (BC MOE 2012a). • The long-term goal of the *Recovery Strategy and Management Plan for the Northern Goshawk, laingi subspecies (Accipiter gentilis laingi) in British Columbia* and management plan for *A. g. laingi* in BC is to ensure viable populations of northern goshawk, *laingi* ssp. persist in each conservation region in BC (NGRT 2008, BC MFLNRO and MOE 2013). The objectives set forth in the 2008 BC Recovery Strategy are to manage, conserve, and recover habitat that meets the needs of the northern goshawk, *laingi* ssp. through its annual cycle; and to conserve and recover well-distributed and viable populations within coastal BC (NGRT 2008). The proposed pipeline corridor crosses the South Coast Northern Goshawk (*laingi* ssp.) Recovery Region (NGRT 2008). The South Coast region contains an estimated 106-116 *A. g. laingi* breeding pairs (NGRT 2008). • The BC *Guidelines for Raptor Conservation* recommend a 500 m buffer around northern goshawk nests in undeveloped areas, and an additional ‘quiet’ buffer (to be determined by a professional biologist) during the breeding season (BC MOE 2013e). The breeding season for northern goshawk is May 7 to August 21(BC MOE 2013e). • Table 7.2.10-10 provides a summary of the predicted change in effective northern goshawk habitat as a result of the Project.

TABLE 7.2.10-8 Cont'd

Indicator	Ecological Context
Olive-sided flycatcher	• The olive-sided flycatcher is Threatened under Schedule 1 of *SARA* and by COSEWIC (COSEWIC 2013, Environment Canada 2013c), is Blue-listed in BC and has a Conservation Framework Priority rating of 2 (BC CDC 2013) and is listed as May Be at Risk in Alberta (ASRD 2011b). • There are approximately 450,000 breeding olive-sided flycatchers within Canada (COSEWIC 2007b). Nationally, observations of olive-sided flycatcher have been declining at an average annual rate of 3.22% (Environment Canada 2013h). Observations of olive-sided flycatchers have been declining in Alberta, but it is not clear if this represents a decline in populations. BC's population appears to be declining at an average annual rate of 3.23% (Environment Canada 2013h). • Olive-sided flycatchers are migratory and present in their Canadian range from late April to September (Campbell *et al.* 1997). • Olive-sided flycatchers are found in coniferous-dominated and mixedwood forest of a variety of forest age classes, but are most often found in fragmented forest habitat with abundant edges (either natural or man-made), mature coniferous forests (especially patches adjacent to water), and burned sites (Campbell *et al.* 1997, COSEWIC 2007b, Wright 1997). They are also found in open woodlands, deciduous woodlands, swamps, floodplain forests, and along steep mountain slopes (Campbell *et al.* 1997, COSEWIC 2007b). • In Alberta, olive-sided flycatchers are most abundant in shrubby and wetland-fringe habitats (Alberta Biodiversity Monitoring Institute 2012). They require access to living trees and snags that are higher than the surrounding vegetation to use as perches, likely because they enhance territory maintenance, mate attraction, and prey detection (Campbell *et al.* 1997, COSEWIC 2007b). On average, foraging trees are 1.4 times taller than the surrounding canopy and are preferentially on steeper slopes (Wright 1997). • Olive-sided flycatchers are considered an early post-fire dependent species. Forest management practices and other human-caused forest disturbances provide additional nesting habitat for this species, but these areas may be ecological sinks as reproductive success is comparatively low on harvested sites than in natural openings (Robertson and Hutto 2007). • The primary threats to olive-sided flycatchers are habitat loss and change, and potentially reduction in insect prey, due to pesticide use (COSEWIC 2007b). • A 2002 study (Waterhouse *et al.* 2003) suggests that representation of old-growth forest by biogeoclimatic zone, forest stand structure, and elevational gradient helps maintain bird diversity. • Environment Canada recommends the following species-specific setback for olive-sided Flycatcher: from May 1 to August 31, a 300 m setback for high disturbance activities, a 150 m setback for medium disturbance activities, and 0-50 m for low disturbance activities (Environment Canada 2011a). • There is no Identified Wildlife Species Account or recovery strategy available for olive-sided flycatcher (BC MOE 2013f, BC MWLAP 2004b). • Table 7.2.10-10 provides a summary of the predicted change in effective olive-sided flycatcher habitat as a result of the Project.

Construction and operations of the proposed pipeline corridor will create new forest clearing, increase the existing corridor width where existing rights-of-way are paralleled, remove potential nesting and perch trees, and require ongoing clearing as part of vegetation management during operations. Although the Footprint will be reclaimed following construction and temporary workspace will be allowed to regenerate to natural vegetation communities, the permanent pipeline right-of-way (18 m wide) will require ongoing clearing during operations to meet safety and regulatory requirements for monitoring. This will result in the long-term maintenance of forest habitat to earlier seral stages (herbaceous and shrub stages). Some disturbed grassland/shrubland and wetland habitats will likely regenerate following reclamation in the medium-term. Sagebrush habitat is expected to regenerate to grassland habitat in the medium-term, and will progress to a sagebrush community over the long-term. Given the planned phased approach to Project construction, sensory disturbance associated with Project construction and reclamation is expected to be relatively localized and of short-term duration. Birds may also experience Project effects related to changes in movement and increased mortality risk during construction (*e.g.*, clearing, sensory disturbance) and operations (*e.g.*, predation risk, reluctance to move across wide openings). The significance evaluation of potential residual effects of Project construction and operations on the bird indicators is summarized in Table 7.2.10-9. The rationale used to evaluate the significance of the residual environmental effects is provided below.

TABLE 7.2.10-9

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON BIRD INDICATORS

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
7. Wildlife Indicator – Grassland/Shrub-steppe Birds									
7(a) Combined Project effects on grassland/shrub-steppe birds resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	LSA	Short-term	Periodic	Long-term	Low	High	Moderate	Not significant

Notes: 1 LSA = Wildlife LSA.

2 Significant Residual Environmental Effect: a high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Change in Habitat

The Project will change the area of available effective habitat for birds. Possible mechanisms for changing effective bird habitat include vegetation clearing, anthropogenic noise and artificial night-time light. Aboriginal participants shared concern about potential effects of the Project on bird habitat, in particular, direct disturbance of nesting trees along large watercourses for raptors (*e.g.*, bald eagle), clearing of nesting habitat for ground nesting birds (*e.g.*, grouse), disturbance of wetland and riparian habitat for ducks and geese, and removal of cavity trees and wildlife trees used by cavity nesting birds. Details of information identified during Aboriginal participation in field studies are provided in the Wildlife Technical Report of Volume 5C.

As a result of vegetation clearing for the Project, earlier seral stages (herbaceous and shrub stages) will replace previously forested areas along the pipeline right-of-way until disturbed areas regenerate following abandonment in the long-term. Grassland/shrub-steppe habitats and wetlands will be revegetated with native vegetation or allowed to revegetate naturally following Project construction.

The wetland assessment estimates approximately 570.4 ha of wetland habitat is encountered by the proposed pipeline corridor, of which 236.2 ha have High Functional Condition, 175.3 ha have High-Moderate Functional Condition, 28.7 ha have Low-Moderate Functional Condition and 0.1 ha have Low Functional Condition (refer to Section 7.2.8 for definitions of wetland functional condition). These estimates reflect the total area of wetlands crossed by the 150 m wide proposed pipeline corridor; however, the expected Footprint will be approximately 45 m wide on average. Therefore, it is anticipated that the area of wetland disturbance will be substantially lower than estimated for the corridor. Monitoring of past projects of similar scope and ecological characteristics have demonstrated that with implementation of appropriate mitigation, wetlands are resilient to pipeline construction disturbance, and habitat function can be restored in the medium to long-term. Additional information and supporting documentation is provided in Section 7.2.8.6.

Vegetation clearing for the Project will directly decrease available bird habitat by removing potential nesting and perch trees and temporarily removing grassland/shrub-steppe and wetland vegetation. The openings created by the Project may also increase bird habitat for forest habitat species that use open spaces for hunting (*e.g.*, northern goshawk) and for habitat generalists (*e.g.*, band-tailed pigeon) or grassland/shrub-steppe specialists (*e.g.*, common nighthawk) (Jalkotzy *et al.* 1997).

As habitat loss increases, the remaining habitat becomes increasingly fragmented or the habitat patches are increasingly isolated, which may compound the effects of habitat loss (Swift and Hannon 2010). Habitat fragmentation occurs when habitat loss results in the remaining habitat becoming increasingly fragmented and/or habitat patches are increasingly isolated (Swift and Hannon 2010). Numerous scientific studies suggest that habitat availability is the primary habitat variable determining species occurrence, distribution and abundance, and that the spatial arrangement of habitat (*i.e.*, fragmentation) has comparatively very little effect on population variables unless the level of habitat loss is very high (Andrén 1994, Cunningham and Johnson 2011, Fahrig 1997, Flather and Bevers 2002, Forman and Collinge 1997, Lichstein *et al.* 2002, Rich *et al.* 1994, Schmiegelow and Mönkkönen 2002, Swift and Hannon 2010, Trzcinski *et al.* 1999). Nonetheless, short and long-term declines of various species of forest birds have been attributed to the reduction and fragmentation of forest cover (Lynch and Whigham 1984, Schmiegelow and Mönkkönen 2002, Sekercioglu *et al.* 2002). Precise determination of the actual magnitude and significance of forest fragmentation is made difficult by virtue of the interaction between a given bird species and factors such as: residual patch size, dynamics, duration and nature of loss (*e.g.*, differences in disturbance between agricultural, urban, industrial, mineral, fire and forestry disturbances); species specialization; and presence of parasitic or generalist predators (*e.g.*, brown-headed cowbird, crows) (Schmiegelow *et al.* 1997, Schmiegelow and Mönkkönen 2002). Habitat fragmentation has been identified as a potential mechanism contributing to population declines for many of the bird indicators including rusty blackbird, spotted owl and northern goshawk (COSEWIC 2006e, COSEWIC 2008e, Greenberg and Matsuoka 2010, NGRT 2008).

Edge effects are the biotic and abiotic conditions that result from the interaction between two adjacent ecosystems separated by an abrupt transition (*i.e.*, the edge) (Murcia 1995). Disturbance-related edge effects occur when changes in the amount of available habitat due to a disturbance extend into a zone of influence immediately adjacent to the disturbed area. Disturbance-related edge effects will occur adjacent to the direct footprint of the Project. New edge effects will be minimal where the proposed pipeline corridor parallels existing linear disturbances. Edge effects can have negative impacts on wildlife. However, there is evidence to suggest that edge effects resulting from oil and gas linear corridors have a minimal effect on birds. A study by Machtans (2006) on seismic lines and boreal forest songbirds found that most birds were able to incorporate seismic lines into their territories, resulting in no change in bird abundance, average location and size of territories. Similarly, a study of edge effects on breeding songbirds south of Grande Prairie, Alberta concluded that species richness and abundance did not differ between edge habitats along pipeline rights-of-way and forested control areas (Fleming and Schmiegelow 2002). It is important to note, however, that Fleming and Schmiegelow (2002) did not differentiate between interior forest specialists and more generalist species. Other potential consequences of increased forest fragmentation and subsequent edge effects on songbirds and owls include increased nest predation (BC MOE 2013h, Vergara 2011) and exposure to the elements (light, temperature, and moisture) (Cadenasso *et al.* 1997).

To minimize vegetation clearing and reduce the fragmentation and isolation of habitat patches, the proposed pipeline corridor parallels existing corridors for approximately 89% (881 km) of its length and incorporates existing disturbances where practical (*e.g.*, shared workspace on adjacent disturbance). The final routing will be aligned to avoid wetlands to the extent feasible. The proposed mitigation measures (Table 7.2.10-3) are expected to reduce residual Project effects on bird habitat by minimizing the area of new disturbance and reclamation of disturbed habitat. The proposed watercourse and wetland crossings will be designed to limit disturbance to wetlands and stream channels, and prevent to erosion and sedimentation, which can adversely affect the invertebrate food supply for birds that forage in streams and wetlands (*e.g.*, dippers, ducks, thrushes, rusty blackbird). Application of sediment control measures from Standards and Best Practices for Instream Works (BC MWLAP 2004a) will prevent siltation in streams and wetlands that provide valuable invertebrate food sources for birds.

The proposed pipeline corridor is within the Sowaqua Spotted Owl WHA (2-498) for approximately 11.5 km. There is a no-net-loss policy for spotted owl habitat in the Sowaqua Spotted Owl WHA. The Project will affect the long-term management goal of the WHA, since clearing for Project construction will result in habitat loss and fragmentation. Consultation with BC MFLNRO regarding the Project's interaction with the WHA and an appropriate approach for mitigating effects has been initiated and is ongoing. A mitigation plan will be developed in consultation with BC MFLNRO, which is anticipated to include measures to avoid, mitigate, restore and offset adverse effects on spotted owl habitat.

The proposed pipeline corridor intersects proposed critical habitat for Williamson's sapsucker and early candidate critical habitat for Lewis's woodpecker (Environment Canada 2013d). Consultation with Environment Canada and BC MFLNRO regarding the Project's interaction with these sensitive habitat areas and an appropriate approach for mitigating effects has been initiated and is ongoing.

High levels of chronic industrial noise have been shown to have a negative effect on birds. Bird species richness, diversity and densities have been demonstrated to be substantially lower in proximity to noisy facilities and roadways compared to less noisy habitats (Bayne *et al.* 2008, Kaseloo 2005, Rheindt 2003). Results of several studies on effects of traffic noise on bird populations suggest that sound levels above 50 dBA can be considered potentially deleterious to some, but not all, bird species (Kasaloo 2005). Bayne *et al.* (2008) demonstrated that noise associated with facilities in boreal Alberta reduced abundance of one third of the songbird species detected, when compared to quiet sites. High levels of ambient noise can also affect mate attraction, pair bonding and territory defense by impairing communication between birds (Brumm 2004, Swaddle and Page 2007). Habib *et al.* (2007) found that chronic industrial noise (*e.g.*, arising from facilities) affected pairing success and age structure of ovenbirds in boreal forests of Alberta. Breeding success of passerines is also reduced in areas near noisy facilities in boreal Alberta (Bayne *et al.* 2008). Brumm (2004) demonstrated that birds in noisier territories sang more loudly than birds at less noisy locations, presumably to mitigate impairment of communication between individuals. High levels of ambient noise can affect mate attraction, pair bonding and territory defense by impairing communication between birds (Brumm 2004, Swaddle and Page 2007). Metabolic costs of increasing song amplitude do not appear to be high, but increased detection by predators may contribute to the costs of increased song amplitude (Brumm 2004). Furthermore, although birds may be able to adapt their song somewhat by increasing amplitude, Rheindt (2003) suggests that most birds are unlikely to have had sufficient time to modify their frequency range to adapt to an increasingly noisy environment. To minimize anthropogenic noise during construction, noise equipment on machinery will be in good working order.

Table 7.2.10-10 and Figures 7.2.10-2 and 7.2.10-3 summarize the predicted change in effective habitat for bird indicators in the Wildlife LSA. Direct disturbance of bird habitat resulting from the Project will be reduced by implementing the measures listed in Table 7.2.10-3 related to habitat loss and alteration, such as pre-construction surveys to identify site-specific habitat features (*e.g.*, nests) and implementing buffers to avoid disturbance, minimizing the area of new footprint, and reclaiming the disturbed footprint to natural vegetation. Grassland and some shrub-dominated habitats (*e.g.*, shrubby wetlands and riparian areas) are likely to regenerate in the medium-term following construction. Residual Project effects on sagebrush grasslands (*e.g.*, shrub-steppe) and forested habitats are predicted to extend over the long-term.

Notes:
1. The nesting life requisite is defined as habitat that is used for nesting and rearing young. It also includes foraging habitat for species that defend territories which include both foraging and nesting habitat (*e.g.*, most songbirds).
2. The growing season generally includes spring, summer and fall. It includes cases where the life requisite habitat is important throughout most of the year, seasonal habitat use can only be roughly differentiated, or the indicator is not present during the winter, as in many migratory bird species.
3. ↓ represents a decrease and ↑ represents an increase.

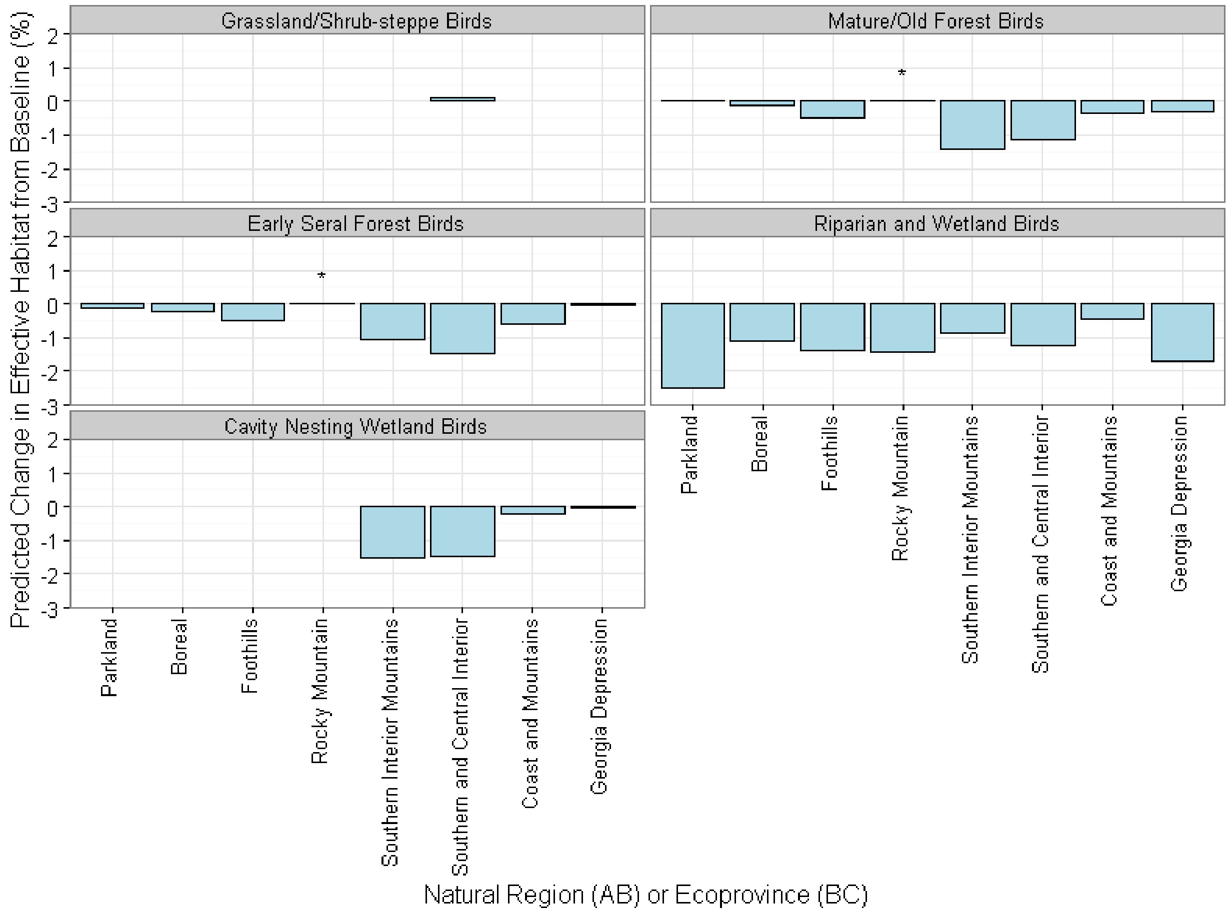

Figure 7.2.10-2 Predicted Change in Effective Habitat for Bird Community Indicators
The change in effective habitat within the Wildlife LSA is presented as the percent change from baseline to Project conditions within each Natural Region in Alberta and Ecoprovince in BC.

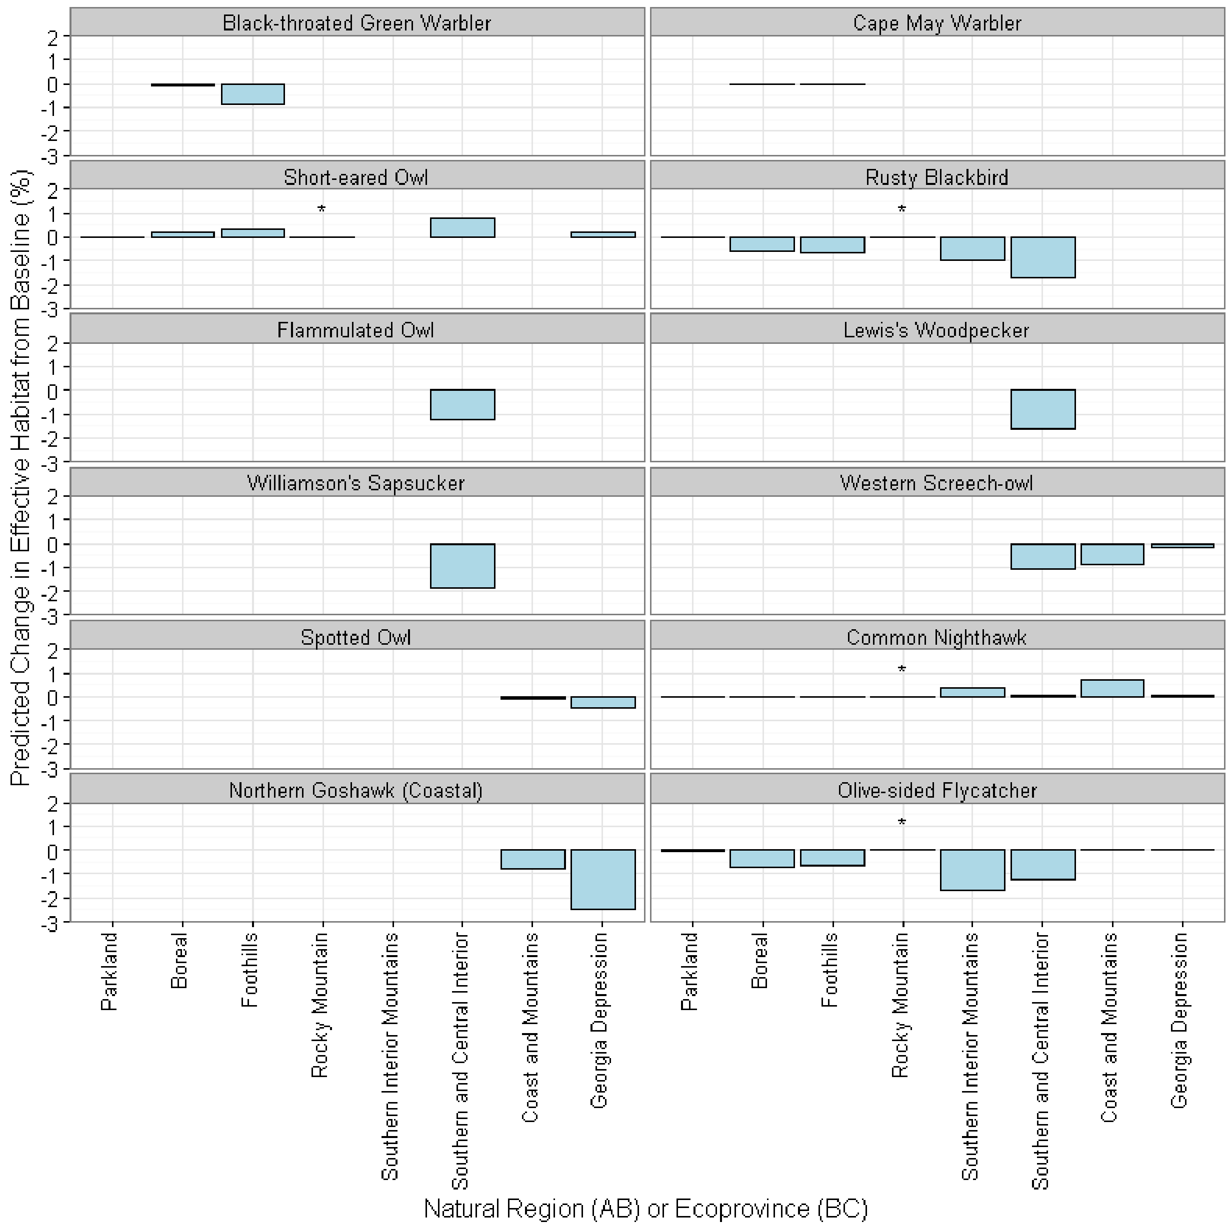

Figure 7.2.10-3 Predicted Change in Effective Habitat for Bird Indicators

The change in effective habitat within the Wildlife LSA is presented as the percent change from baseline to Project conditions within each Natural Region in Alberta and Ecoprovince in BC. Both the interior and coastal western screech-owl are provided in the results at the species level, but can be distinguished by the Ecoprovince (*i.e.*, interior subspecies occurs within the Southern and Central Interior Ecoprovince; coastal subspecies occurs within the Coast and Mountains, and Georgia Depression Ecoprovince).

Change in Movement

The Project will require new clearing, create new linear disturbance and increase the width of existing linear disturbance features. The Footprint may act as a filter or barrier for movement of some bird species. Forest gaps have been shown to affect movements of forest birds (Bayne *et al.* 2005, Desrochers and Hannon 1997, Fleming and Schmiegelow 2002) and owls (COSEWIC 2008e). Wider corridor widths increase barrier effects on bird movements more than narrower corridors (Desrochers and Hannon 1997), and parallel forest openings can cause a cumulative barrier effect at the landscape scale for some species (Bélisle and St. Clair 2001). Desrochers and Hannon (1997) found that gaps less than 30 m in width had little effect on bird movements, though wider gaps constrained movement for specific species. Residual forest patches, or detours, may facilitate bird movements across gaps (Desrochers and Hannon 1997, St. Clair *et al.* 1998).

Changes in movement patterns may also occur as some species are attracted to early seral vegetation. Species that prefer edges and habitat generalists are most likely to use disturbed areas (Jalkotzy *et al.* 1997). Species that use open spaces for hunting (*e.g.*, northern goshawk), foraging (*e.g.*, sandhill crane) or nesting (*e.g.*, grassland/shrub-steppe birds, short-eared owl, common nighthawk) may also benefit.

With the proposed mitigation (*e.g.*, sharing workspace with the adjacent right-of-way to reduce the construction right-of-way-width, minimum disturbance construction, where feasible, reduce grubbing near watercourses, wetlands, and other wet areas to facilitate the restoration of deciduous tree and shrub communities), forest openings resulting from the Project and other existing disturbances are expected to result in filters, but not complete barriers to movement of some bird species.

Increase Mortality Risk

Vegetation clearing, human activity (including traffic and equipment operations) and artificial lighting have potential to affect bird mortality risk. Birds are particularly vulnerable during the nesting stage. Bird mortality during construction may occur if nests are encountered during vegetation clearing for construction of the Project. Construction activities also have potential to increase bird mortality risk by disrupting bird nesting and breeding behaviour to an extent that causes nest failure or abandonment of the breeding area. Most bird species are sensitive to human disturbance in proximity to nest sites and often have physiological or behavioural responses (Antoniuk and Ainsle 2003) that may result in population effects such as nest desertion, reduced parental care of young, decreased feeding efficiency and increased dispersal distances of young (Hill *et al.* 1997, Jalkotzy *et al.* 1997, Richardson and Miller 1997). 'Flushing' is a common short-term response of birds to disturbance, where birds temporarily leaving the nest or perch site in response to unfamiliar noises, pedestrian approach or traffic (*e.g.*, vehicle, boat, aircraft, ATV) (Antoniuk and Ainsle 2003).

Declines of various species of birds have been attributed to the reduction and fragmentation of forest cover (Lynch and Whigham 1984, Sekercioglu *et al*. 2002, Schmiegelow and Mönkkönen 2002). Increased risk of nest predation resulting from edges in forested landscapes is a potential issue for some breeding birds, particularly ground nesters (Flaspohler *et al.* 2001). Numerous studies in forested landscapes have found no evidence of increased nest predation due to either forestry (Bayne and Hobson 1997, Cotterill and Hannon 1999, Ibarzabal and Desrochers 2001, Schmiegelow and Mönkkönen 2002) or roads (Ortega and Capen 1999). Regional differences in predator communities can also influence the potential effects of fragmentation on nest predation (Chalfoun *et al.* 2002). A study by Cavitt and Martin (2002) found that forest fragmentation was related to an increase in nest predation east of the Rocky Mountains (in the US), but that nest predation decreased with fragmentation west of the Rocky Mountains.

Artificial night-time light sources attract songbirds that migrate at night and can increase bird mortality risk from collisions, excessive energy expenditure and predation (Jones and Francis 2003, Poot *et al.* 2008). Light pollution from the Project facilities will be reduced by using directional or shielded lighting, where practical. Aboriginal participants identified potential effects of the Project on mortality risk through physical (*e.g.*, riparian vegetation clearing) and sensory disturbance (*e.g.*, noise) of nests and nesting habitat during construction for several bird species including bald eagle, hawks, geese and ducks (Wildlife Technical Report of Volume 5C).

The proposed mitigation (Table 7.2.10-3) is expected to reduce the residual effects of the Project on increased bird mortality risk. Where practical, clearing and construction activities will be scheduled outside the migratory bird nesting period of March 15 to August 15 in BC (Wilson pers. comm.) and the migratory bird restricted activity period (RAP) of May 7 to August 20 in Alberta (Gregoire pers. comm.). Otherwise, potential effects of clearing and construction on bird mortality risk during the nesting period will be mitigated by conducting non-intrusive area searches for evidence of nesting (*e.g.*, presence of singing birds, territorial males, alarm calls, distraction displays). Any active nests will be subject to site-specific mitigation measures.

Summary of Effects Characterization Rationale for Bird Indicators

A summary of the rationale for the effects characterization for the bird indicators is provided below. Environmental and/or regulatory standards considered in the evaluation of magnitude are provided in Table 7.2.10-8 (ecological context bird indicators) and Section 7.2.10.4 (regulatory guidelines). The criteria rating and rationale for spatial boundary, duration, frequency, reversibility, probability and confidence are similar for all of the bird indicators:

- Spatial Boundary: Wildlife LSA – changes to habitat, movement and mortality risk may extend beyond the cleared construction right-of-way (Footprint) into the Wildlife LSA (*e.g.*, edge effects or sensory disturbances).
- Duration: short-term – the events causing effects (*i.e.*, vegetation removal during construction or site-specific maintenance events; vegetation control during operations) occur during the construction phase or will be completed in less than 1 year during operations.
- Frequency: periodic – the events causing effects (*i.e.*, clearing, traffic and activity) occur during construction and intermittently during operations for monitoring, vegetation control and maintenance.
- Reversibility: long-term – effects are reversible in the long-term following decommissioning and abandonment, once native vegetation regenerates over the Project Footprint.

Re-establishment of herbaceous and shrub vegetation on the disturbed Footprint is expected to occur in the short to medium-term following reclamation; however, residual effects on treed wetland habitats and adjacent terrestrial western toad habitats will extend over the long-term. The reversibility of combined Project effects on western toad (*i.e.*, change in habitat, movement and mortality risk) is constrained by the long-term timeline for reclamation of treed habitats (*i.e.*, greater than 10 years following Project construction).

- Probability: high – the Project will alter habitat, cause sensory disturbance and increase mortality risk to affect the indicator.
- Confidence: moderate – the assessment is based on a good understanding of cause-effect relationships and relevant data. Limitations and uncertainty associated with available data pertinent to the Project area reduce the confidence level to moderate.

The criteria ratings and rationale for magnitude vary and are provided below for each bird indicator.

Grassland/Shrub-steppe Birds

- Magnitude: low – several grassland/shrub-steppe bird species with conservation status of concern occur in the Wildlife LSA. The proposed mitigation (*e.g.*, minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects on the grassland/shrub-steppe bird community to low.

Mature/Old Growth Forest Birds

- Magnitude: medium – several mature/old forest bird species with conservation status of concern occur in the Wildlife LSA. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low for most species in the mature/old forest bird community. Additional mitigation will be applied to reduce the magnitude of residual effects on particularly sensitive species/habitats (*e.g.,* refer to spotted owl assessment rationale below). Given the sensitivity of some species in the mature/old forest bird community, the magnitude of residual effects is concluded to be medium.

Early Seral Forest Birds

- Magnitude: low – several early seral forest bird species with conservation status of concern occur in the Wildlife LSA. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects on the early seral forest bird community to low.

Riparian and Wetland Birds

- Magnitude: low – a number of riparian and wetland bird species with conservation status of concern occur in the Wildlife LSA. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects on the riparian and wetland bird community to low.

Wood Warblers

- Magnitude: low – the wood warbler indicator group includes species of conservation concern. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects on wood warblers to low.

Short-eared Owl

- Magnitude: low – short-eared owls are designated as Special Concern under Schedule 1 of *SARA* and by COSEWIC, May Be at Risk in Alberta and Blue-listed in BC. Short-eared owls are sensitive to disturbance, particularly sensory disturbance during the nesting period. The proposed mitigation (*e.g.,* minimizing the Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low.

Rusty Blackbird

- Magnitude: low – rusty blackbird is designated as Special Concern under Schedule 1 of *SARA* and by COSEWIC and is Blue-listed in BC. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low.

Flammulated Owl

- Magnitude: low – flammulated owl is designated as Special Concern under Schedule 1 of *SARA* and by COSEWIC and is Blue-listed in BC. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low.

Lewis's Woodpecker

- Magnitude: medium - Lewis's woodpecker is designated as Threatened under Schedule 1 of *SARA* and by COSEWIC and is Red-listed in BC. Lewis's woodpecker populations have declined in total numbers, extent of occurrence and area of occupancy. The loss or degradation of suitable breeding habitat is believed to be a limiting factor for Lewis's woodpecker in BC. Small population size and low density makes the species particularly sensitive to disturbance and habitat loss. The proposed pipeline corridor intersects early candidate critical habitat for Lewis's woodpecker. Consultation with Environment Canada and BC MFLNRO regarding the Project's interaction with candidate critical habitat areas and an appropriate approach for mitigating effects has been initiated and is ongoing. With application of appropriate mitigation, the residual effects on Lewis's woodpecker are concluded to be medium magnitude.

Williamson's Sapsucker

- Magnitude: medium – Williamson's sapsucker is designated as Endangered under Schedule 1 of *SARA* and by COSEWIC and is Blue-listed in BC. Primary threats to Williamson's sapsucker include its small population size making the species vulnerable to extirpation, and habitat loss due to logging of mature or old western larch and Douglas-fir stands. Williamson's sapsuckers are generally tolerant of disturbance and often forage near or within forest openings. The Project intersects proposed critical habitat for Williamson's sapsucker. Consultation with Environment Canada and BC MFLNRO regarding the Project's interaction with proposed critical habitat and an appropriate approach for mitigating effects has been initiated and is ongoing. With application of appropriate mitigation, the residual effects on Williamson's sapsucker are concluded to be medium magnitude.

Western Screech-owl

- Magnitude: low – the interior (*macfarlanei*) subspecies of western screech-owl is designated as Endangered under Schedule 1 of *SARA*, Threatened by COSEWIC and is Red-listed in BC. The coastal (*kennicotti*) subspecies is designated as Special Concern under Schedule 1 of *SARA*, Threatened by COSEWIC, and is Blue-listed in BC. The species has undergone substantial decline across its range in BC. Small population size and low density makes the species particularly sensitive to disturbance and habitat loss. Habitat loss from forestry activities is the primary threat to both subspecies of western screech-owl. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low.

Great Blue Heron

- Magnitude: low – both subspecies of great blue heron are Blue-listed in BC. *A. g. fannini* is Special Concern under Schedule 1 of *SARA* and by COSEWIC. Proposed mitigation includes alignment of the final Project route to avoid known heron nesting colonies, applying appropriate minimum disturbance buffers, and scheduling clearing and construction outside sensitive time periods. With implementation of mitigation, the residual Project effects on great blue heron are expected to be of low magnitude.

Spotted Owl

- Magnitude: medium – spotted owl is Endangered under Schedule 1 of *SARA* and by COSEWIC and is Red-listed in BC. The population has experienced substantial declines and the species is vulnerable to extinction due to small densities, habitat loss and barred owl competition. There is a no-net-loss policy for spotted owl habitat in the Sowaqua Spotted Owl WHA (2-498) crossed by the proposed pipeline corridor. Construction of the Project in this WHA is inconsistent with the long-term management goal of the WHA, since clearing will result in habitat loss and fragmentation. Consultation with BC MFLNRO regarding the Project's interaction with the WHA and an appropriate approach for mitigating effects has been initiated and is ongoing. A mitigation plan will be developed in consultation with BC MFLNRO, which is anticipated to include measures to avoid, mitigate, restore and offset adverse effects on spotted owl habitat. With application of the appropriate measures, the magnitude of residual Project effects on spotted owl is concluded to be medium.

Bald Eagle

- Magnitude: low – bald eagle is listed as Sensitive in Alberta and the proposed pipeline corridor traverses Sensitive Raptor Range for bald eagle along the Edmonton to Hinton Segment. Bald eagle is not a species of conservation concern in BC, as populations have been increasing in numbers, often in areas with substantial human development. Bald eagles have high cultural value for Aboriginal communities. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, scheduling activities outside of sensitive periods) is expected to reduce the magnitude of residual Project effects to low.

Common Nighthawk

- Magnitude: low – common nighthawk is Threatened under Schedule 1 of *SARA* and by COSEWIC, Sensitive in Alberta, and Yellow-listed in BC. The proposed mitigation (*e.g.,* minimizing the Project

Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low.

Northern Goshawk

- Magnitude: low – coastal northern goshawk (*laingi* ssp.) is Threatened under Schedule 1 of *SARA* and by COSEWIC and is Red-listed in BC. Goshawks are considered sensitive to habitat disturbance. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, scheduling activities outside of sensitive periods, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low.

Olive-sided Flycatcher

- Magnitude: low – olive-sided flycatcher is Threatened on Schedule 1 of *SARA* and by COSEWIC, May Be at Risk in Alberta, and Blue-listed in BC. The proposed mitigation (*e.g.,* minimizing the Project Footprint, avoiding active nests, and reclaiming the Footprint to natural vegetation) is expected to reduce the magnitude of residual Project effects to low.

7.2.10.11 Significance Evaluation of Potential Residual Effects on Amphibian Indicators

Two habitat-based community indicators were selected to assess potential Project effects on amphibians: pond-dwelling amphibians; and stream dwelling amphibians (Section 7.2.10.1). Project construction and operations activities have the potential to affect amphibians by causing changes in habitat, movement and mortality risk. Detailed species accounts are described in the Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C.

Relevant regulatory guidelines, information identified during Aboriginal participation in field studies, and ecological context was considered in the characterization of potential residual effects for the amphibian indicators. A summary of ecological and regulatory context is provided in Section 7.2.10.4. In general, regulatory and planning objectives relevant to amphibians include conserving wildlife habitat, particularly for species at risk, and maintaining biodiversity. Measures to identify, protect, buffer, and restore wetlands and riparian habitat are recommended in LRMPs, SRMPs and Protective Notation (PNT) along the proposed pipeline corridor. Consultation details regarding wildlife and Aboriginal participation in the wildlife field studies are provided in the Wildlife Technical Report of Volume 5C. Additional consultation information is summarized in Section 3.0.

Information on the ecological context for each amphibian indicator (*e.g.,* species status, population trends, known threats, best management practices and conservation strategies) is provided in Table 7.2.10-11. The purpose of the ecological context is to provide an indication of the resilience of each indicator to disturbance effects.

TABLE 7.2.10-11

ECOLOGICAL CONTEXT SUMMARY FOR AMPHIBIAN INDICATORS

Species	Ecological Context
Pond-dwelling amphibians	• The pond-dwelling amphibians indicator includes 14 species of amphibians that use wetland habitats for one or more life requisites (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C), including the following species with conservation status of concern (AESRD 2012a, ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - Canadian toad (May Be at Risk in Alberta); - Columbia spotted frog (Yellow-listed in BC, Conservation Framework Priority 2; Sensitive in Alberta); - Great Basin spadefoot (Threatened under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 1); - northern leopard frog (Endangered under Schedule 1 of *SARA* and by COSEWIC; at Risk in Alberta); - northern red-legged frog (Special Concern under Schedule 1 of *SARA*; Blue-listed in BC, Conservation Framework Priority 1); - Oregon spotted frog (Endangered under Schedule 1 of *SARA* and by COSEWIC, Red-listed in BC, Conservation Framework Priority 1); - tiger salamander (Special Concern by COSEWIC, Secure in Alberta); - long-toed salamander (Yellow-listed in BC; Sensitive in Alberta; Special Concern by Alberta's ESCC); and - western toad (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2; Sensitive in Alberta). • The Oregon spotted frog is restricted to the lower mainland of BC. The population of Oregon spotted frogs in BC declined by approximately 17% between 1997 and 2010 (COSEWIC 2011c). • No population estimate is available for northern red-legged frogs in BC. The species is locally common in some surveyed areas, but suitable habitats are largely under-surveyed (COSEWIC 2002d). Northern red-legged frogs are presumed to be declining due to habitat conversion and an increasing number of bullfrogs in suitable habitats (COSEWIC 2002d). • Western toad is widespread and locally common in a variety of habitats in BC; however, no long-term data sets or abundance estimates are available for this species (COSEWIC 2002e). Western toad juveniles experience high mortality rates and populations can fluctuate in response to climatic conditions. It is presumed that in southern BC western toad have experienced widespread declines and extirpations (COSEWIC 2002e). In Alberta, western toads are locally common (COSEWIC 2002e). • Although there is no accurate count of Great Basin spadefoots, there are an estimated 5,000 to 10,000 individuals in Canada's population (COSEWIC 2007c). There are currently insufficient data to assess population trends for Great Basin spadefoot in Canada; however, the amount of habitat loss suggests that the species is likely experiencing declines. Annual fluctuations in population numbers due to varying water levels and recruitment success increases the species vulnerability to local extirpation (COSEWIC 2007c). • Records of Columbia spotted frog observations suggest that their populations in BC are declining in areas where they were formerly abundant (Ovaska and Govindarajulu 2010). The population size and trend of Columbia spotted frog in Alberta is uncertain; however, they are known to occur at low density and their distribution is discontinuous (James 1998). • Well connected aquatic and terrestrial habitats are required by pond-dwelling amphibians to complete all stages of their life cycle (BC MWLAP 2004c). Some common species that may be encountered by the Project are boreal chorus frogs, Pacific tree frogs, wood frogs, northwestern salamanders and rough-skinned newts (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C). • Amphibian breeding occurs in various natural and artificial aquatic habitats, including permanent and ephemeral ponds, slow streams, shallow margins of lakes, marshes, swamps, bogs, ditches, road ruts and borrow pits (COSEWIC 2002e, 2007c, 2011a, Stevens *et al.* 2006a,b, Wind and Dupuis 2002). Emergent vegetation is preferred by northern red-legged frogs and northern leopard frogs, while Oregon spotted frogs and spadefoots prefer lower amounts of emergent vegetation (BC MWLAP 2004b, COSEWIC 2002d, 2011a, Wagner 1997). • Oregon spotted frogs, Columbia spotted frogs and northern leopard frogs overwinter in ponds that include springs, seeps and low-flow channels that do not freeze. Frogs may bury themselves into silty soil or vegetation to hibernate (BC MOE 2013i, COSEWIC 2011c, Wagner 1997). • Outside of the breeding season, pond-dwelling amphibians can be found in a variety of habitats including wetlands, forests, meadows, riparian areas and muskeg (Matsuda *et al.* 2006, Ovaska and Govindarajulu 2010). Terrestrial adult amphibians (*e.g.*, northern red-legged frogs, western toads, wood frogs, long-toed salamanders and newts) use mature, moist forested habitats with adequate leaf litter and cover objects (*e.g.*, fallen logs, coarse woody debris) for thermal and security cover year round (COSEWIC 2002d,e, BC MOE 2013i, Russell and Bauer 2000). Great Basin spadefoots require terrestrial habitats for underground retreat year-round, including grasslands, shrub-steppe and open forest with loose, friable soils that can be easily burrowed into (BC MWLAP 2004b). Northern leopard frogs, Canadian toads, chorus frogs, and tiger salamanders can be found in a variety of terrestrial habitats outside of breeding season, including grasslands, meadows and open forests (BC MOE 2013i, Russell and Bauer 2000). • Outside of the breeding season, pond-dwelling amphibians can be found in a variety of habitats including wetlands, forests, meadows, riparian areas and muskeg (Matsuda *et al.* 2006, Ovaska and Govindarajulu 2010). Terrestrial adult amphibians (*e.g.*, northern red-legged frogs, western toads, wood frogs, long-toed salamanders and newts) use mature, moist forested habitats with adequate leaf litter and cover objects (*e.g.*, fallen logs, coarse woody debris) for thermal and security cover year round (COSEWIC 2002d,e, BC MOE 2013i, Russell and Bauer 2000). Great Basin spadefoots require terrestrial habitats for underground retreat year-round, including grasslands, shrub-steppe and open forest with loose, friable soils that can be easily burrowed into (BC MWLAP 2004b). Northern leopard frogs, Canadian toads, chorus frogs, and tiger salamanders can be found in a variety of terrestrial habitats outside of breeding season, including grasslands, meadows and open forests (BC MOE 2013i, Russell and Bauer 2000). • Browne *et al.* (2009) suggest landscape variables are more influential to western toad relative abundance than quality of breeding habitat. Even if breeding habitat remains intact, loss or degradation of key terrestrial habitat can potentially result in detrimental impacts to western toad populations (Browne and Paszkowski 2010).

TABLE 7.2.10-11 Cont'd

Species	Ecological Context
Pond-dwelling amphibians (cont'd)	• Disturbed habitats are potentially population sinks for breeding pond-dwelling amphibians (Gyug 1999, Stevens *et al.* 2006a), and research has found that western toads do not use anthropogenic disturbance for hibernating (Browne and Paszkowski 2010). • Primary threats to pond-dwelling amphibians include habitat loss and fragmentation due to agricultural and urban expansion, habitat degradation (including pollution), barriers to movement, water-table changes, road mortality, and predation and competition from non-native species (BC MWLAP 2004c, COSEWIC 2011c). • Disease outbreak or parasite infection (*i.e.*, chytrid fungus, *Aeromonas* bacteria, *Saprolegnia* fungus, trematode infections, *Batrachochytrium dendrobatidis*) have caused population collapses in the US; chytrid fungus has been detected in frogs and toads in southern BC (Deguise and Richardson 2009). Disease and parasites could result in rapid extirpations, or local extinctions, of toad populations in BC (Wind and Dupuis 2002). • Best management practices for pond-dwelling amphibians include preserving wetlands, maintaining natural hydrology, maintaining sufficient terrestrial habitat (and access to it) for amphibians to complete all life history phases, mitigating road mortality and reducing the spread of introduced species (BC MWLAP 2004c). • The *Western Toad Working Report* (Davis 2002) identifies research and management priorities for western toad in BC as long-term monitoring, reducing mortality of adult toads, and study of dispersal patterns and habitat selection. Currently there are no provincial or federal recovery strategies or management plans for western toad (BC MOE 2013f, Environment Canada 2013c). In Alberta, the *Best Management Guidelines for the Enhanced Approval Process* recommends a year-round 100 m buffer around wetlands that provide breeding habitat for western toad for all levels of disturbance (Government of Alberta 2013a). In BC, there is a recommended a minimum 30 m setback distance for western toad breeding ponds (BC MOE 2012a). • The goal of the *Recovery Strategy for the Oregon spotted frog (*Rana pretiosa*) in British Columbia* is to maintain and restore extant populations, expand these populations where feasible, and to establish new self-sustaining population. The recovery objectives for the Oregon spotted frog are to: protect and restore habitat at known occupied locations in the lower mainland of BC and at additional occupied sites if found or established; reduce mortality of all life stages; inventory potentially suitable habitat; monitor population status to determine effectiveness of protection and habitat enhancement; and address knowledge gaps in the life-history, population ecology, threats, and habitat requirements of the species (Canadian Oregon Spotted Frog Recovery Team [COSFRT] 2012). • The objective of the *Management Plan for the Northern Leopard Frog (*Lithobates pipiens*), Western Boreal/Prairie Populations, in Canada* (Environment Canada 2013k) is to maintain and increase the western boreal/prairie populations of the species. The proposed pipeline corridor intersects potentially suitable habitat for northern leopard frogs between Edmonton and Edson. Threats to the species and its habitat should be identified, reduced or eliminated, where possible, through population monitoring, habitat conservation, stewardship, research, and reintroduction of the species (Environment Canada 2013k). In Alberta, the *Integrated Standards and Guidelines – Enhanced Approval Process* (Government of Alberta 2013a) recommends a year-round 100 m setback for northern leopard frog breeding ponds. • The goal of the *Recovery Strategy for Great Basin spadefoot (*Spea intermontana*) in British Columbia* (BC Southern Interior Reptile and Amphibian Recovery Team [SIRART] 2008a) is to ensure that there is sufficient, secure habitat distributed throughout the historic range to maintain self-sustaining populations of Great Basin spadefoot in BC. The objectives of the strategy are to secure known, wetland, breeding and terrestrial habitats throughout the historic range; increase knowledge on the distribution, habitat requirements, population processes, terrestrial movements, threats, population viability, and important habitats; and increase understanding by stakeholders. • The *Ecological Area Assessment for the Lac du Bois Grasslands Protected Area* identifies habitat potential for Great Basin spadefoots in Batchelor Lake and in other alkaline ponds in the Lac du Bois Grasslands Protected Area, and recommends protection of these ponds by fencing and signage (Grasslands Conservation Council of British Columbia 2009). • A year-round 200 m setback is recommended for high disturbance activities and 100 m for medium disturbance activities from long-toed salamander breeding ponds (Government of Alberta 2013a). The proposed pipeline corridor intersects a PNT identified as a Rare and Endangered Species Habitat Protection Area for long-toed salamander along the Edmonton to Hinton Segment (Wildlife Technical Report of Volume 5C). The proposed pipeline corridor is located more than 200 m from the identified ponds. Recommended mitigation in the PNT includes restriction of vehicular activity in spring and early fall to reduce effects during the breeding and dispersal periods (Wilkinson pers. comm.). There is also a known long-toed salamander breeding pond located at the Hinton Pump Station. The pond is located within 200 m of the existing disturbances. • Currently there are no provincial or federal recovery strategies or management plans for Canadian toad (BC MOE 2013f, Environment Canada 2013c). In Alberta, the *Integrated Standards and Guidelines – Enhanced Approval Process* recommend a year-round 100 m setback for Canadian toad breeding ponds (Government of Alberta 2013a). The distribution of Canada toads along the proposed pipeline corridor is limited, potentially occurring between Edmonton and Spruce Grove. In this area, suitable habitat is limited due to existing development and land use. • Table 7.2.10-13 provides a summary of the predicted change in effective pond-dwelling amphibian habitat as a result of the Project. Refer to Table 7.2.10-8 and Section 7.2.8 for information on wetland function, including habitat function.

TABLE 7.2.10-11 Cont'd

Species	Ecological Context
Stream-dwelling amphibians	• The stream-dwelling amphibians indicator includes the following species (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C) (BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - coastal tailed frog (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 1); and - Pacific giant salamander (Threatened under Schedule 1 of *SARA* and by COSEWIC; Red-listed in BC; Conservation Framework Priority 1). • While coastal tailed frogs are moderately widespread and can be common locally, there is very limited information available regarding population size and densities in BC (BC MWLAP 2004b, COSEWIC 2011d). Matsuda and Richardson (2005) surveyed clear-cut and mature second growth forests near Chilliwack, BC and found approximately 60 adults/ha. • A rough estimate of Pacific giant salamanders suggested approximately 20,000 adults in BC, however, the cryptic nature of the species results in a large error associated with the estimate (Pacific Giant Salamander Recovery Team [PGSRT] 2010). The known range of the Pacific giant salamander has not changed substantially in recent history; however, land use practices may be reducing high quality habitats within the species' range (PGSRT 2010). • Aquatic and terrestrial habitats are required for different life stages for both coastal tailed frog and Pacific giant salamander (BC MWLAP 2004b, COSEWIC 2011d). Streams with step-pool morphology adjacent to old forest with abundant understory are preferred habitat for this species (BC MWLAP 2004b). Year-round streamflow is critical for tadpole survival as they spend up to 4 to 6 years instream before morphing into adult form (BC MOE 2012a). • The proposed pipeline corridor crosses early candidate critical habitat for Pacific giant salamander (Environment Canada 2013d), for which a federal recovery strategy has not yet been completed. The Wildlife Technical Report in Volume 5C provides additional information regarding candidate critical habitats. • Preferred breeding streams for both stream-dwelling amphibian species are cool, fish-free, boulder-rich mountain streams that are ice-free in winter (Matsuda *et al.* 2006). They prefer moist, old and mature forest habitat, although maturing forests are also suitable (Matsuda *et al.* 2006, COSEWIC 2011d). They are often found in forests with dense herb and fern cover, although they are not associated with any particular plant species or communities (COSEWIC 2011d). • During terrestrial life phases, coastal tailed frog and Pacific giant salamander juveniles and adults inhabit both the breeding stream and wet, forested habitats close to the streams. Adequate cover objects (*i.e.*, coarse woody debris) must be present on the stream banks and in the surrounding forest for shelter. Individuals may be found up to 50 m from the stream bank (BC MWLAP 2004b, COSEWIC 2011d). Pacific giant salamander adults may be terrestrial or can exhibit facultative neoteny (aquatic adults). Pacific giant salamander neotenes live in streams, and can sometimes occur in larger waterbodies at lower elevations (BC MWLAP 2004b). • Coastal tailed frogs sometimes use instream and terrestrial habitats within clear-cut areas. Clear-cuts can cause stream siltation and alter hydrological regimes, which can negatively impact tailed frog breeding success (Dupuis and Steventon 1999, Wahbe *et al.* 2004). There is some evidence that the density of coastal tailed frog tadpoles is greater in streams running through clear-cuts, which may be linked to increased primary productivity in clear-cuts (Wahbe *et al.* 2004). • Primary threats to stream-dwelling amphibians include habitat loss and degradation (including erosion, siltation, changes in stream flow and structure, removal of riparian vegetation), barriers to movement, predation, and disease (BC MWLAP 2004b, COSEWIC 2011d). • Best management practices for stream-dwelling amphibians include maintaining moist forested habitat with abundant coarse woody debris along streams (at least 30 m extending from both stream banks), avoiding siltation of stream habitats, avoid altering stream-flow patterns, and maintaining abundant in-stream cover (BC MWLAP 2004c). • BC MOE recommends a 30-50 m setback distance for stream-dwelling amphibian breeding streams, and an additional 20-30 m buffer within which disturbance should be minimized (BC MOE 2012a). Where slopes exceed 60%, recommended riparian avoidance buffers extend beyond the top of the ravine (BC MOE 2012a). • The goal of the Recovery Strategy for the Pacific giant salamander (*Dicamptodon tenebrosus*) in British Columbia (PGSRT 2010) is to ensure a well-connected, viable, and self-sustaining population within secure habitat. The short-term objectives are to secure known populations, prevent fragmentation, inventory for unidentified populations, and restore historical populations. • Table 7.2.10-13 provides a summary of the predicted change in effective coastal tailed frog habitat as a result of the Project.

Construction and operations of the Project will create new forest clearing, increase the existing corridor width where existing rights-of-way are paralleled, remove potential site-specific habitat features (*e.g.*, coarse woody debris, small mammal burrows used as daily retreats or for hibernation), and require ongoing clearing as part of vegetation management during operations. The Project will interact with amphibian indicators via all three of the identified effects pathways, including changes in habitat, changes in movement and increased risk of mortality. Table 7.2.10-12 provides a summary of the significance evaluation of the potential residual effects of the construction and operations of the proposed Project on the amphibian indicators. The rationale used to evaluate the significance of the residual environmental effects is provided below.

TABLE 7.2.10-12

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON AMPHIBIAN INDICATORS

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
24. Wildlife Indicator – Pond-dwelling Amphibians									
24(a) Combined Project effects on pond-dwelling amphibians resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	LSA	Short-term	Periodic	Long-term	Medium	High	Low	Not significant
25. Wildlife Indicator – Stream-dwelling Amphibians									
25(a) Combined Project effects on stream-dwelling amphibians resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	LSA	Short-term	Periodic	Long-term	Medium	High	Moderate	Not significant

Notes: 1 LSA = Wildlife LSA.

2 Significant Residual Environmental Effect: a high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Change in Habitat

The Project will change the area of available effective habitat for amphibians. Possible mechanisms for changing effective amphibian habitat include site clearing (wetland and terrestrial habitats), watercourse crossings and soil handling (including trenching). Aboriginal participants raised concerns about potential effects of the Project on amphibian habitat, in particular, direct disturbance, contamination and loss of wetland or stream habitat during construction and operations of the Project (Wildlife Technical Report of Volume 5C).

Vegetation clearing for the Project will disturb both wetland and terrestrial amphibian habitat. Amphibian abundance is often lower in cleared areas and second-growth stands than in mature forests due to changes in micro-climate (Wind 1999). Clearing of wetland and riparian vegetation around ponds and streams can affect the temperatures that amphibians are exposed to both in aquatic and terrestrial habitats (Newton and Cole 2013, Semlitsch *et al.* 2008). Variation in temperatures in breeding ponds and streams can affect the breeding success, tadpole development and survival, and immunity to disease for amphibians (Lucas and Reynolds 1967, Raffel *et al.* 2006). Temperature and moisture variation caused by vegetation and tree clearing in the terrestrial habitat surrounding breeding ponds and streams can affect the dispersal and survival of juvenile and adult amphibians (Naughton *et al.* 2000, Semlitsch *et al.* 2009, Walston and Mullin 2008).

Standard best practices for protecting pond-dwelling amphibian habitat include a recommended set-back distance from breeding ponds (BC MOE 2012a, BC MWLAP 2004c, Government of Alberta 2013a). However, a study by Browne and Paszowski (2010) demonstrated that wetland-based buffers are not sufficient or realistic for protecting some pond-dwelling amphibian (*e.g.*, western toad) hibernation sites, since individuals can move long distances from breeding ponds to hibernation sites. Maintenance of stream structure, complexity and condition, as well as maintenance of riparian habitat buffers are standard best practices for protecting stream-dwelling amphibians. BC MOE (2012a) recommends disturbance buffers and trenchless crossing methods, where possible, to protect suitable amphibian breeding streams. Stream-dwelling amphibians generally remain closer to breeding habitat during terrestrial life stages than do pond-dwelling amphibians. The proposed mitigation measures to reduce disturbance and facilitate restoration of amphibian breeding and terrestrial habitat include minimizing the area of disturbance (including implementing riparian protection buffers to the extent practical), implementing minimal disturbance construction in key habitats, controlling erosion and sedimentation, maintaining streamflow during crossing construction, and reclamation of disturbed habitat to natural vegetation communities (Table 7.2.10-3).

The Project is predicted to change the availability of amphibian habitat in the wildlife LSA (Table 7.2.10-13 and Figure 7.2.10-4). The western toad and Great Basin spadefoot have specific terrestrial habitat requirements and therefore the habitat change was quantified in addition to habitat change for the pond-dwelling amphibian community indicator. The coastal tailed frog range is substantially larger than the Pacific giant salamander and, therefore, the quantification of habitat change for this species will encompass that of the other species in the stream-dwelling amphibians community indicator.

TABLE 7.2.10-13

PREDICTED CHANGE IN HABITAT FOR AMPHIBIAN INDICATORS IN THE WILDLIFE LSA

Wildlife Indicator	Habitat/Life Requisite	Habitat Suitability Rating	Existing Conditions (ha)	Project Conditions (ha)	Incremental Change (ha)[1]	% Change
Pond-dwelling amphibians	Reproductive habitat	High	8,019.8	7,934.5	85.3 ↓	1.06 ↓

Note: 1 ↓ represents a decrease and ↑ represents an increase.

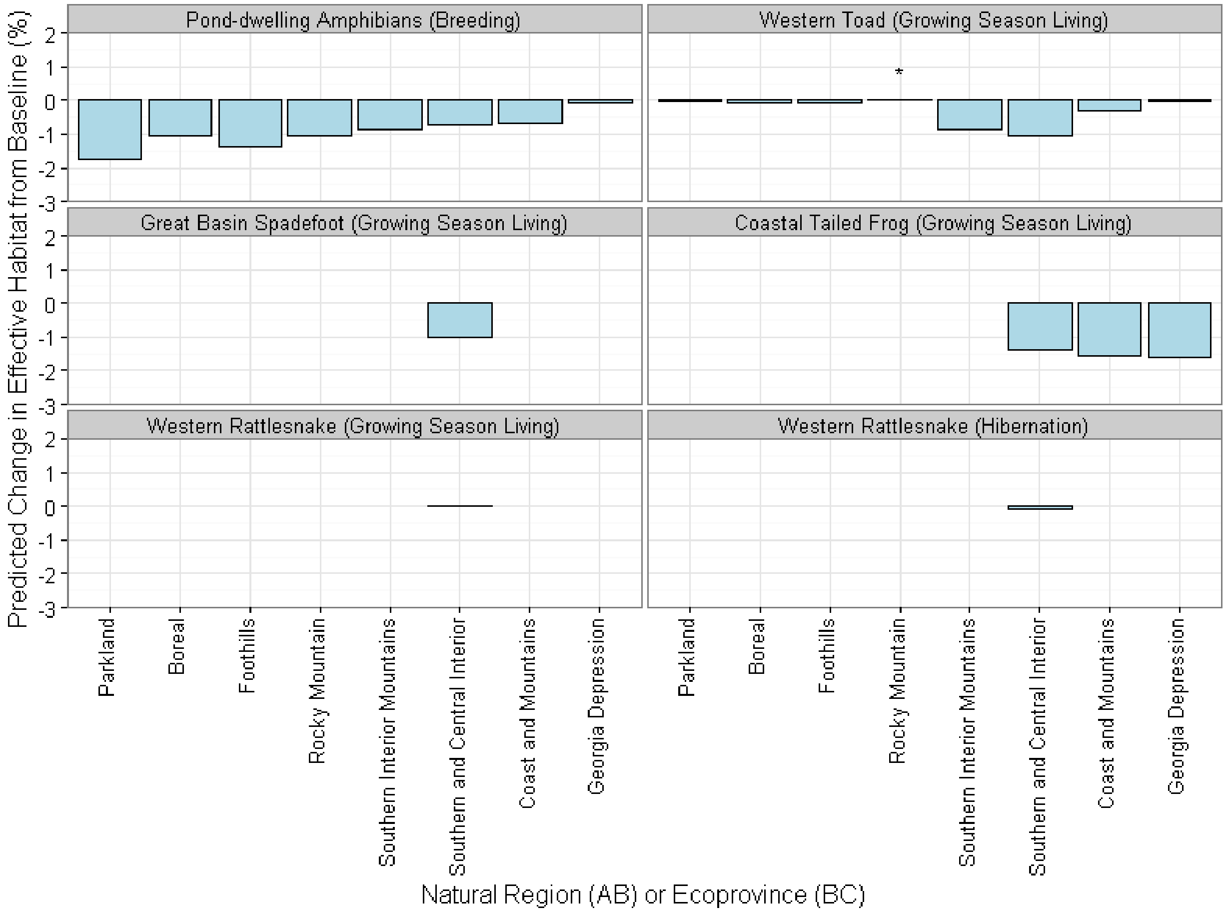

Figure 7.2.10-4 Predicted Change in Effective Habitat for Amphibian and Reptile Indicators
The change in effective habitat within the Wildlife LSA is presented as the percent change from baseline to Project conditions within each Natural Region in Alberta and Ecoprovince in BC.

Change in Movement

Construction of the Project may create barriers to amphibian movement (*e.g.,* spoil piles, brush piles, traffic, strung pipe, open trench), depending on the location of the final Project alignment relative to breeding and upland habitats, and the season of construction. The extent of amphibian movement across the landscape varies between species. Pond-dwelling amphibians may stay in or near the same waterbody during their lifetime, or may migrate seasonally, sometimes for extended distances. Habitat connectivity and movement can be affected by anthropogenic disturbances such as low fences (*e.g.*, sediment or snow fences), soil berms, ditches, deep ruts, roads, or high-impact development (*e.g.*, industrial, commercial, urban, residential areas). The following summarizes typical movement patterns of pond- and stream-dwelling amphibian species that may interact with the Project.

- Oregon spotted frogs may move several hundred metres between breeding and winter habitats (COSFRT 2012). Oregon spotted frogs require connected aquatic habitat for annual movements (COSFRT 2012).

- Great Basin spadefoots utilize habitats in proximity to breeding areas. Maximum dispersal distances from breeding ponds may be as large as 370 m (Garner 2012). Spadefoots move overland.

- A study by Browne and Paszkowski (2010) found that radio tracked western toads in boreal forests of north-central Alberta travelled a distance, on average, of about 1 km between breeding and hibernation sites. Non-breeding western toad habitat is typically within 2 km of breeding areas, but distances of up to 7 km along watercourses have been recorded (Davis 2002). Western toads move overland by climbing and crawling (Wind and Dupuis 2002).

- Seasonal movement by Columbia spotted frogs varies by individual. Some individuals complete their entire life cycle in or near the same lake or pond, while others use different water bodies for breeding, summer feeding and overwintering (James 1998). Male Columbia spotted frogs in Idaho remained within 200 m of breeding ponds, while female frogs moved up to 1 km from breeding ponds to summer habitats (Pilliod *et al.* 2002). In Oregon, Bull and Hayes (2001) measured movements of 15 m to 560 m by some frogs, while approximately half of the frogs remained in the breeding ponds year-round.

- Wood frogs, long-toed salamanders, northwestern salamanders and roughskin newts migrate between breeding ponds and non-breeding terrestrial habitats. Wood frogs travelled an average of 1.2 km away from their ponds, and have been recorded migrating up to 2.5 km away from their ponds (Berven and Grudzien 1990). Female wood frogs generally travel longer distances than males (Regosin *et al.* 2003). Long-toed salamanders migrate seasonally and generally return to the same breeding ponds (Beneski *et al.* 1986), dispersing up to 1.2 km (Funk and Dunlap 1999 in Smith and Green 2005). Roughskin newts may migrate up to several hundred metres, often during or after seasonal rains; males migrate earlier than females (NatureServe 2012).

- Stream-dwelling amphibians typically move within the immediate riparian zone (less than 5 m from the stream) (Matsuda and Richardson 1999). However, both Pacific giant salamanders and coastal tailed frogs have been detected several hundred metres from streams under moist conditions (Ascaphus Consulting 2003, BC MWLAP 2004b). In a study by Wahbe *et al.* (2000), newly emerged juvenile tailed frogs were detected up to 100 m from natal streams.

Application of the proposed mitigation measures (Table 7.2.10-3) is expected to reduce the magnitude of potential residual effects of Project construction and operations on amphibian movement. Leaving periodic gaps in windrows (*i.e.*, grubbing piles, topsoil/root zone material, grade spoil, rollback, strung pipe), avoiding grubbing in shrubby wetlands, and moving any amphibians that are observed on the construction right-of-way will facilitate amphibian movement during Project construction. If warranted, sedimentation fences may be used during construction to redirect amphibian movement away from the construction site. Silt fences used to prevent amphibians from accessing the active construction site, as well as for erosion control, will be removed once they are no longer necessary to prevent barriers to amphibian movement following construction. Recontouring disturbed surface soils to remove deep ruts will also prevent barriers to movement.

Increased Mortality Risk

The Project will increase the risk of amphibian mortality. Possible mechanisms for increasing the risk of amphibian mortality include heavy machinery and vehicle traffic, predation risk, creation of artificial ponds and reduced water quality (*e.g.*, sedimentation). Site clearing, watercourse crossings and vehicle traffic (Beasley 2006, Davis 2002, Wind and Dupuis 2002) will potentially increase mortality risk for pond-dwelling amphibians during construction and operations (*e.g.*, site-specific maintenance activities). Aboriginal participants shared concern about potential effects of the Project on amphibian mortality risk due to increased traffic on roads accessing the work site, and from habitat contamination associated with potential pipeline spills and leaks (Wildlife Technical Report of Volume 5C). The proposed mitigation measures listed in Table 7.2.10-3 (*e.g.*, conducting an amphibian salvage at breeding locations if amphibians are present during construction; moving any amphibians observed on the construction right-of-way or in the trench; using sediment fencing or other measures to redirect dispersing amphibians away from the construction site; minimizing grubbing in shrubby wetland areas to avoid creating pitfall traps) will reduce the potential residual effect of the Project on amphibian mortality risk associated with amphibians moving into and/or becoming trapped in the work site.

Amphibian species that will potentially interact with the Project are not freeze-tolerant, and require thermally stable retreat habitat to overwinter. Suitable hibernation habitats include abandoned small mammal burrows, cover objects or soil (provided soil texture is loose enough to allow burrowing below the depth of frost). The immobility of ground-hibernating animals increases their vulnerability to soil disturbance during the winter (COSEWIC 2002d,e, 2007c). Great Basin spadefoots rely on underground retreats year-round. Soil compaction due to machinery and vehicles can decrease amphibians' ability to burrow into the soil and, therefore, potentially increase mortality due to desiccation or predation (COSEWIC 2007c, Garner 2012). Proposed mitigation measures listed in Table 7.2.10-3 (*e.g.*, conducting an amphibian salvage at known sensitive amphibian species breeding locations if construction is scheduled during the amphibian breeding season; moving any amphibians observed on the construction right-of-way; implementing measures such as packing snow or using mats to avoid excessive soil compaction on the Footprint, particularly in proximity to wetlands and watercourses) are expected to reduce the potential residual effect of the Project on amphibian mortality risk as a result of hibernation habitat disturbance.

Construction activities have potential to create artificial ponds, which can increase amphibian mortality risk. Borrow pits, road ditches, vehicle ruts, and grubbing can create small areas of ponded water. Under coniferous tree cover, pools of such small size would typically be too cold during spring for amphibian breeding, but in open conditions they are sufficiently warm and, therefore, can be attractive breeding sites for pond-dwelling amphibians (*e.g.*, western toads and Oregon spotted frogs) (Gyug 1999, Stevens *et al.* 2006a,b). Artificial ponds often have unfavourable environments for developing embryos and larvae because they dry out too quickly, or have nutrient-limited conditions that limit primary production and available algal food resources for developing larvae (Gyug 1999, Stevens *et al.* 2006a). As a result, artificial ponds can be population sinks for pond-dwelling amphibians (COSFRT 2012, Gyug 1999, Stevens *et al.* 2006a). The proposed mitigation measures listed in Table 7.2.10-3 (*e.g.*, reclaim borrow pits; avoid construction during wet conditions that will create excessive soil rutting, and/or grade ruts in construction access and within the Footprint where rutting cannot be avoided; reduce grubbing in wetlands, riparian areas and wet areas to the extent practical) are expected to avoid creating small pools that are unsuitable for amphibian breeding, and reduce the potential residual Project effect on amphibian mortality risk.

Amphibians are sensitive to water contamination (BC MWLAP 2004c). They can be adversely affected by the high conductivity of water in breeding ponds, which is often related to total dissolved solids, organic or mineral particles, disturbance, or runoff with high sediment levels (Browne *et al.* 2009). Mitigation measures that limit disturbance to wetlands, stream channels and riparian areas, and prevent erosion and sedimentation, are expected to reduce residual Project effects on water quality, and associated amphibian mortality risk. The Emergency Response Plan, which will include prevention, containment and clean-up measures, is expected to alleviate any potential effects on amphibian mortality risk associated with exposure to contaminants (*e.g.*, leaks, spills or chemical release).

During construction and operations, the Footprint may increase amphibian mortality risk, since, like other small animals, amphibians are susceptible to predation in open and unvegetated areas (Gyug 1999, Wind and Dupuis 2002). Oregon spotted frogs and red-legged frogs experience increased predation at various life stages in disturbed areas due to predatory species such as bull frog, raccoon and striped skunk, which are well-adapted to human disturbance (COSFRT 2012). Implementation of the Waste Management Program will reduce the potential for attracting species that may depredate amphibians (*e.g.*, ravens, racoons). Measures to reduce the Footprint, use minimum disturbance construction techniques and reclaim the Footprint to natural vegetation communities will further reduce the residual effect of Project clearing on predation risk for amphibians.

Summary of Effects Characterization Rationale for Amphibian Indicators

A summary of the rationale for the effects characterization for the amphibian indicators is provided below. Environmental and/or regulatory standards considered in the evaluation of magnitude are provided in Table 7.2.10-11 (ecological context for amphibian indicators) and Section 7.2.10.3 (regulatory guidelines). The criteria rating and rationale for spatial boundary, duration, frequency, reversibility and probability are similar for all of the amphibian indicators.

- Spatial Boundary: Wildlife LSA – changes in habitat, movement and mortality risk for the amphibian indicators will primarily be focused on the Footprint, but may extend into the Wildlife LSA.

- Duration: short-term – the events causing effects (*i.e.*, clearing and soil handling, vehicle watercourse crossing installation and removal, instream pipeline installation, construction-related barriers to amphibian dispersal, heavy machinery and vehicle traffic) occur during the construction phase or will be completed in less than 1 year during operations (*i.e.*, site-specific maintenance events).

- Frequency: periodic – the events causing effects (*i.e.*, construction and site-specific maintenance events during operations) will occur intermittently but repeatedly over the assessment period.

- Reversibility: long-term – changes in aquatic habitats resulting from Project construction (*i.e.* water crossings) or sediment introduction (erosion, run-off), are expected to be alleviated in the short to medium-term with application of appropriate mitigation and reclamation measures. Changes in instream habitat, movement barriers and mortality risk are primarily limited to the construction period (*i.e.*, reversible in the short-term). Re-establishment of graminoid and shrub dominated wetland, riparian and upland vegetation on the disturbed Footprint is expected to occur in the short to medium-term following reclamation; however, residual effects on treed wetland and riparian habitats and adjacent terrestrial amphibian habitats will extend over the long-term. Effects are reversible in the long-term following decommissioning and abandonment, once native vegetation regenerates over the Project Footprint.

- Probability: high – the Project will alter habitat and increase mortality risk to affect the indicator.

The criteria rating and rational for magnitude and confidence vary, and are provided below for each bird indicator.

Pond-dwelling Amphibians

- Magnitude: medium – several pond-dwelling amphibian species with conservation status of concern occur in the Wildlife LSA. The proposed corridor traverses suitable habitat for the Oregon spotted frog and Great basin spadefoot, both of which are of conservation concern and have limited geographic ranges within BC, which may make them particularly sensitive to disturbance. The proposed mitigation measures are consistent with the available guidelines and regulatory recommendations, and are expected to reduce the residual effects of the Project on pond-dwelling amphibians to medium magnitude.

- Confidence: low – the assessment is based on a good understanding of cause-effect relationships for habitat and movement effects, and relevant data. Limitations and uncertainty associated with available data pertinent to the Project area, and the potential extent of disturbance to hibernating amphibians during winter construction, reduce the confidence level to low. Supplemental field surveys will be conducted to collect additional information on amphibian occurrence along the final pipeline alignment, which will inform the development of mitigation and increase prediction confidence.

Stream-dwelling Amphibians

- Magnitude: medium – coastal tailed frog and Pacific giant salamander are species of conservation concern. Coastal tailed frogs were observed in streams surveyed along the proposed pipeline corridor. The proposed pipeline corridor traverses early candidate critical habitat for Pacific giant salamanders. There were no confirmed detections of Pacific giant salamander during field surveys for the Project. The proposed mitigation measures are consistent with the available guidelines and regulatory recommendations to reduce riparian and instream habitat loss, and reclaim disturbed habitats. Consultation with Environment Canada regarding the Project's interaction with the candidate critical habitat and an appropriate approach for mitigating effects has been initiated and is ongoing. It is anticipated that, if warranted, an appropriate mitigation strategy (in addition to the measures recommended in Section 7.2.10.6) will be developed to reduce the magnitude of residual Project effects on stream-dwelling amphibians to medium magnitude.

- Confidence: moderate – the assessment is based on a good understanding of cause-effect relationships and relevant data. Limitations and uncertainty associated with available data pertinent to the Project area reduce the confidence level to moderate.

7.2.10.12 Significance Evaluation of Potential Residual Effects on Reptile Indicator

Arid habitat snakes were selected as a habitat-based community indicator for the assessment of potential Project effects on reptiles. The arid habitat snake community includes western rattlesnake, Great Basin gopher snake, yellow-bellied racer, rubber boa and garter snakes. Given the suite of snake species with conservation status of concern (species at risk are typically sensitive to change and good environmental indicators) in arid habitats, particularly the dry southern interior region of BC, as well as the high value (identified in consultation; refer to Section 3.0) and sensitivity of grassland habitats in this region, this reptile indicator is expected to provide a conservative estimate of the potential Project effects on reptiles. For similar reasons, western rattlesnake was identified as a suitable species to model change in habitat. Project construction and operational activities have the potential to affect arid habitat snakes by causing changes in habitat effectiveness, movement and mortality risk. A detailed species account for western rattlesnake is described in the Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C.

Relevant regulatory guidelines, information identified during Aboriginal participation and ecological context were considered in the characterization of potential residual effects for arid habitat snakes. A summary of regulatory guidelines is provided in Section 7.2.10.4. In general, regional planning guidelines have little or no information specific to snakes or other reptile species. Planning objectives relevant to reptiles include conserving wildlife habitat, particularly for species at risk, and maintaining biodiversity. The Kamloops LRMP (BC ILMB 1995) aims to maintain viable populations of all species by ensuring habitat needs are met, and to restore species that are endangered or threatened by human activities. This goal may be accomplished by maintaining and/or enhancing a diversity of viable grassland ecosystems. The Ecological Area Assessment for the Lac du Bois Grasslands Protected Area identifies Batchelor Hills and the Lac du Bois Gateway areas as high value core habitat for arid habitat snakes. Wildlife objectives include maintenance of habitat integrity and connectivity, creating buffers between protected areas and development, and mortality prevention (Grasslands Conservation Council of British Columbia 2009).

The compilation of ATK, including the collection of TEK through Aboriginal field participation and engagement, provided valuable information about wildlife along the proposed pipeline corridor. No concerns regarding the potential effects of the Project on reptiles were identified. Consultation and engagement details regarding wildlife, ATK and TEK are provided in the Wildlife Technical Report of Volume 5C, and this information is included and considered throughout the effects assessment for arid habitat snakes. Consultation with BC MFLNRO and local biologist identified existing information available about reptiles habitat and recommended the area from RK 837 to RK 842 as suitable habitat for arid habitat snakes and surveys.

Information on the ecological context for this indicator (*e.g.,* species status, population trends, known threats, best management practices and conservation strategies) is provided in Table 7.2.10-14. The purpose of including the ecological context is to provide an indication of the resilience of the indicator to disturbance effects.

TABLE 7.2.10-14

ECOLOGICAL CONTEXT SUMMARY FOR THE REPTILE INDICATOR

Reptile Indicator	Ecological Context
Arid Habitat Snakes	• The arid habitat snakes indicator includes the following species (Wildlife Habitat Modelling and Species Accounts Technical Report of Volume 5C) (ASRD 2011b, BC CDC 2013, COSEWIC 2013, Environment Canada 2013c): - western rattlesnake (Threatened under Schedule 1 of the *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - gopher snake, *deserticola* ssp. (Threatened under Schedule 1 of *SARA* and by COSEWIC; Blue-listed in BC; Conservation Framework Priority 2); - yellow-bellied racer (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Blue listed in BC; Conservation Framework Priority 2); - rubber boa (Special Concern under Schedule 1 of *SARA* and by COSEWIC; Yellow-listed in BC; Conservation Framework Priority 1); and - common and terrestrial gartersnakes (Yellow-listed in BC). • The number of snakes in BC is unknown. Due to their cryptic nature and mobility, accurate population estimates have not been possible (Racer Management Team Working Group [RMTWG] 2013, SIRART 2008b,c). • The population estimate for western rattlesnake in BC (extrapolated from counts at known den sites) is approximately 7,900 individuals (Hobbs 2013). This is likely inaccurate due to fluctuation in den counts and the likelihood of undiscovered dens. • Based on the slow reproductive rates, high mortality rates, habitat loss of up to 52% and known local extirpations, the populations of snakes in BC are likely declining (COSEWIC 2004a,b, SIRART 2008b,c). Snakes have discontiguous ranges in BC (COSEWIC 2004a,b), increasing vulnerability to local extirpation. • Arid habitat snakes are restricted to warm, dry habitats including grasslands, ponderosa pine and Douglas-fir forests. Well connected seasonal habitats are required to complete all aspects of the snakes' life history, including hibernating, mating, foraging, and egg-laying. • Dens located in rocky outcrops and talus slopes on south-facing slopes are used for hibernating. Rattlesnakes hibernate communally, at times with other snake species including gopher snakes and racers (Bertram *et al.* 2001, COSEWIC 2004b,c). Gopher snakes and racers also hibernate singly or in small non-specific groups (COSEWIC 2002f, Bertram 2004). • Open grassland and dry forest habitats as well as riparian areas are preferred by rattlesnakes, gopher snakes, and racers for foraging and mating during the active season (COSEWIC 2002f, 2004a,b). • Egg-laying habitat for gopher snakes and racers includes south-facing open areas, with adequate cover. This may include talus, rock fissures, coarse woody debris, abandoned rodent burrows or excavated chambers in sandy soil (BC MWLAP 2004b, Bertram 2004, COSEWIC 2002f). • Rubber boas potentially use a variety of habitats in the southern interior and south coast ecoprovinces, and may occur in the Project area from Black Pines to Westridge. Garter snakes likely occur along the length of the Project from Edmonton to Westridge, in forests, grasslands, riparian areas, wetlands and meadows encountered by the proposed pipeline corridor. • Since populations are seasonally concentrated at hibernating sites, arid snake species are particularly vulnerable to disturbance and local extirpation. Habitat loss and direct mortality due to road construction, utility development, agricultural expansion and urban expansion are the main threats to these species (SIRART 2008b,c). • Best management practices for arid habitat snakes include implementing disturbance buffers around known den sites, preserving important migration and foraging habitats, maintaining corridors for movement between summer and winter habitats, mitigating road mortality, and discouraging killing of snakes (BC MWLAP 2004c). • The goal of the provincial *Recovery Plan for the Gopher Snake deserticola ssp. (Pitophis catenifer deserticola) in British Columbia* (SIRART 2008b) is to maintain self-sustaining populations of the gopher snake, *deserticola* ssp. throughout its range. The specific objectives include: protecting habitat, including suitably connected sites with sufficient habitat for hibernation, egg laying, foraging, and seasonal movements; addressing road kill of snakes at identified sites; and increasing understanding and knowledge of gopher snake ecology and threats. • The goal of the *Management Plan for the Racer (Coluber constrictor) in British Columbia (RMTWG 2013)* is to maintain the current area of occupancy and distribution by protecting and conserving suitable habitat, reducing roadkill, and quantifying racer habitat needs, population demographics, and viability within all 5 population areas. • The goal of the *Recovery Strategy for the Western Rattlesnake (Crotalus oreganus) in British Columbia* (SIRART 2008c) is to maintain self-sustaining populations throughout the species' range. The objectives are to: protect and manage threats to habitat, consisting of suitably connected priority sites with sufficient habitat for hibernation, foraging, gestation, and seasonal movements; reduce road kill mortality of snakes; and develop a research program to increase knowledge of western rattlesnake distribution, population size and demography, habitat use, movements, and threats. • The Ecological Area Assessment for the Lac du Bois Grasslands Protected Area identifies Batchelor Hills and the Lac du Bois Gateway areas as high value core habitat for western rattlesnake and other snake species including the racer, gopher snake and rubber boa. There are three known den sites in the area, and telemetry studies have shown extensive active season movements. The Ecological Area Assessment recommends that wildlife fencing be considered if traffic increases on the Lac du Bois road and that signage be increased for motorized vehicle access control (Grasslands Conservation Council of British Columbia 2009). • Table 7.2.10-16 provides a summary of the predicted change in effective western rattlesnake habitat as a result of the Project.

Construction and operations of the Project will disrupt movement and increase mortality risk due to soil handling and trenching, increase the existing corridor width where existing rights-of-way are paralleled, remove habitat structural features including coarse woody debris and rocks that provide cover for both snakes and small mammal prey species, and increase traffic. The Project will result in the long-term conversion of shrubby sagebrush habitat to grassland. With appropriate construction and reclamation practices, disturbed grassland habitat within the Footprint is expected to regenerate in the short to medium-term following Project construction and reclamation.

The Project is predicted to interact with arid habitat snakes via all three of the identified effects pathways, including changes in habitat, changes in movement and increased risk of mortality. Table 7.2.10-15 provides a summary of the significance evaluation of the potential residual effects of the construction and operations of the proposed pipeline on arid habitat snakes. The rationale used to evaluate the significance of the residual environmental effects is provided below.

TABLE 7.2.10-15

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT CONSTRUCTION AND OPERATIONS ON THE REPTILE INDICATOR

				Temporal Context						
	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Duration	Frequency	Reversibility	Magnitude	Probability	Confidence	Significance[2]
26.	Wildlife Indicator – Arid Habitat Snakes									
26(a)	Combined Project effects on arid habitat snakes resulting from habitat loss or alteration, changes in movement and increased mortality risk.	Negative	LSA	Short-term	Periodic	Long-term	Medium	High	Moderate	Not significant

Notes: 1 LSA = Wildlife LSA.

2 Significant Residual Environmental Effect: a high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Change in Habitat

Project clearing and construction activities will disturb grassland, shrub-steppe and open forest habitat, and site-specific habitat features such as rocks, talus, outcrops and coarse woody debris that comprise suitable habitat components for arid habitat snakes. Disturbance of these habitats is predicted to reduce cover availability for arid habitat snakes as well as their prey species, and alter the availability of effective snake habitat within the Project Footprint. Due to the slow life history (*i.e.*, mature slowly, low reproductive rate) of snakes in temperate regions, they are not resilient to landscape changes (Waldron *et al.* 2013). Snakes are predominantly found under or near cover objects including coarse woody debris, rocks and woody vegetation, used for thermal and security cover (Bertram *et al.* 2001, Gomez 2007). Arid habitat snakes primarily prey on small mammals. Disturbed grassland areas have fewer prey species and at lower density, resulting in lower prey availability for snakes (Grant *et al.* 1982, LoBue and Darnell 1959). A study of western rattlesnakes in southern BC found that snakes in disturbed areas had lower body condition than snakes in undisturbed areas and, therefore, were likely to have lower reproductive rates and survival (Lomas 2013).

The Project is predicted to change the availability of western rattlesnake habitat in the Wildlife LSA (Table 7.2.10-16 and Figure 7.2.10-4). Results of habitat modelling indicate a small increase in effective living habitat for western rattlesnake as a result of the Project, which is a function of clearing of treed habitat in the dry interior region of BC. Of the species within the arid habitat snakes indicator community, the western rattlesnake has the most restricted distribution due to historical extirpation, and least variable habitat requirements of the species in the arid snake community. Therefore, the quantification of habitat change for western rattlesnake is expected to provide a precautionary indication of potential Project effects on arid habitat snakes. Standard best practices for protecting snakes include maintaining buffers of undisturbed native vegetation around breeding, foraging, egg-laying and hibernating habitats

(BC MWLAP 2004c). Application of the proposed mitigation (Table 7.2.10-3), including minimizing the area of disturbance, implementing minimal disturbance construction to the extent feasible, protecting site-specific habitat features habitat features of importance (*e.g.*, rock outcrops) where practical, and restoration of disturbed habitat, is expected to reduce the magnitude of potential residual effects of Project construction and operations on snake habitat.

TABLE 7.2.10-16

PREDICTED CHANGE IN HABITAT FOR WESTERN RATTLESNAKE IN THE WILDLIFE LSA

Wildlife Indicator	Habitat/Life Requisite	Habitat Suitability Rating	Existing Conditions (ha)	Project Conditions (ha)	Incremental Change (ha)[1]	% Change
Western rattlesnake (arid habitat snakes indicator)	Year-round living habitat	High	205.5	204.9	0.5 ↓	0.26 ↓
		Moderate	1048.1	1048.6	0.5 ↑	0.05 ↑
		Low	1438.6	1438.6	< 0.1 ↓	< 0.01 ↓
		Nil	775.9	775.9	< 0.1 ↓	< 0.01 ↓
		Effective Habitat	1253.5	1253.5	< 0.1 ↑	< 0.01 ↑
	Hibernating	High	48.5	48.5	< 0.1↓	0.04↓
		Moderate	50.4	50.3	0.1↓	0.16↓
		Low	0	0	0	0
		Nil	3,372.7	3,372.8	0.1↑	< 0.01↑
		Effective Habitat	98.9	98.8	0.1↓	0.10↓

Note: 1 ↓ represents a decrease and ↑ represents an increase.

Change in Movement

The Project may affect snake movement during construction. Soil and brush piles, traffic and movement of heavy machinery, strung pipe and the pipeline trench could create barriers to snake dispersal. The degree of changes in snake movement will depend on the location of construction activities relative to snake hibernacula and foraging habitats, and the season of construction.

The extent of snake movement across the landscape varies between species. Western rattlesnakes are philopatric (loyal to winter hibernacula), undergoing annual migrations between hibernacula and foraging habitats. These movements range from hundreds of metres to several kilometres (Gomez 2007, Gosling 2013). Gravid females do not migrate and move as little as 10-100 m during the active season (Macartney and Gregory 1988). Great Basin gopher snakes have been known to travel as far as 2.4 km from their hibernation site (Williams *et al.* 2012). The maximum dispersal distance between hibernacula by racers in Utah was measured at 1.8 km (Brown and Parker 1976).

Roads have been found to create barriers to snake dispersal (Jackson and Fahrig 2011, Shepard *et al.* 2008). All snake species experience immobilization (a defensive response where a snake freezes to avoid being detected by a threat) due to traffic. For gopher snakes and racers, the immobilization is momentary; however, for rattlesnakes, immobilization can be extended and may affect their overall dispersal success (Andrews and Gibbons 2005).

Brush and debris piles may create artificial cover features for snakes, which are often found under man-made cover objects (Bertram *et al.* 2001). This may affect natural dispersal patterns.

Increased Mortality Risk

The Project has potential to increase the risk of snake mortality as a result of heavy machinery and vehicle traffic, soil handling and trenching, predation risk, and persecution.

Road kill is a substantial source of mortality for snakes in BC (COSEWIC 2002f, 2003b, 2004a,b). Road mortalities can result in severe "depletion effects" on snake populations (Hobbs 2013, Jackson and Fahrig 2011). Mortality on roads also leads to road avoidance and potential genetic isolation of snake populations (Shepard *et al.* 2008).

Arid habitat snakes (*e.g.*, rattlesnake, gopher snake, racer, rubber boa) are ground-dwelling snakes, with limited climbing abilities (Bertram *et al.* 2001). Snakes that may enter the pipeline trench during construction would likely not be capable of getting out, putting the animal at risk of thermal stress, predation and mortality from equipment, backfilling or human-wildlife conflict.

The primary defense mechanisms against predation used by arid habitat snakes are crypsis (camouflage) and shelter under cover objects (Andrews and Gibbon 2005, COSEWIC 2002f, 2004a,b). Disturbance of snake habitats, including clearing of cover objects and vegetation, exposes snakes to predation by predator species such as hawks and coyotes. Immobilization due to vehicle traffic can increase exposure to predation, as snakes are likely to freeze in place without seeking a safe place to hide (Andrews and Gibbons 2005).

Active persecution of rattlesnakes is prevalent. Although individuals of the species are protected like other animals by the BC *Wildlife Act*, Sections 2(4), 26(2) and 75(1) of the Act provide for the killing of wildlife if a threat to person or property exists. Due to the venomous nature of the rattlesnake and its reputation, the perception of a threat is common and many snakes are killed in situations where the animal could have easily been avoided (Bertram *et al.* 2001, Charland *et al.* 1993). A primary strategy for defense by the gopher snake is to imitate the rattlesnake by shaking its tail and making a rattle noise in the throat. Unfortunately, this often leads humans to mistake harmless gopher snakes for venomous rattlesnakes and to kill the animal in perceived defense (Bertram *et al.* 2001).

Application of the proposed mitigation measures (Table 7.2.10-3), including implementing protective buffers around known hibernacula or breeding sites and scheduling construction activities in identified snake habitats outside the active period (*i.e.*, from April to October), is expected to reduce potential residual Project effects on snake mortality risk due to machinery, vehicles, open trench, and human-wildlife conflict (BC MWLAP 2004c). An education program will be mandatory for all construction staff, and will include measures to avoid snakes and appropriate protocols in the event that a snake is detected on the work site. This mitigation is expected to effectively prevent the killing of snakes that may be perceived as a threat.

Summary of Effects Characterization Rationale for Reptile Indicator

A summary of the rationale for the effects characterization for the arid habitat snakes indicator is provided below. Environmental and/or regulatory standards considered in the evaluation of magnitude are provided in Table 7.2.10-14 (ecological context for the arid habitat snakes indicator) and Section 7.2.10.4 (regulatory guidelines).

- Spatial Boundary: Wildlife LSA – habitat changes (*e.g.*, removal of cover) are expected to be primarily limited to the Project Footprint; changes (*e.g.*, barriers) to movement (*e.g.,* spoil piles, traffic) would likely extend to the Wildlife LSA; and changes in mortality risk (*e.g.*, traffic) are assessed at the regional scale.
- Duration: short-term – the events causing effects are construction and operational activities (*e.g.*, monitoring, vegetation management and site-specific maintenance).
- Frequency: periodic – the events causing effects (*i.e.*, clearing, traffic and activity) will occur during construction and intermittently during operations for monitoring, vegetation control and maintenance.
- Reversibility: long-term – the arid habitat snake community relies primarily on grassland, shrub-steppe and open forest habitats. Grassland habitats are expected to regenerate on the Project Footprint in the short to medium-term. Sagebrush and open forest habitats are expected regenerate in the long-term. Effects are reversible in the long-term following decommissioning and abandonment, once native vegetation regenerates over the Project Footprint.
- Magnitude: medium - the arid habitat snake community includes several species with both provincial and federal conservation status designations of concern. Snake populations in BC are assumed to be declining based on their slow reproductive rates, high mortality rates, habitat loss of up to 52%, and known local extirpations. The slow life history of snakes in the Wildlife LSA means they are not resilient to habitat change. The disconnected distribution of snakes in BC increases their vulnerability to local extirpation. The proposed mitigation to reduce Project effects on snake habitat, movement

and mortality risk are consistent with available best practices and conservation objectives, and are expected to reduce the residual effects of the Project on arid habitat snakes to medium.

- Probability: high – the Project will alter habitat and increase mortality risk to affect the indicator.
- Confidence: moderate – the assessment is based on a good understanding of cause-effect relationships and relevant data. Limitations and uncertainty associated with available data pertinent to the Project area reduce the confidence level to moderate.

7.2.10.13 Summary of Residual Effects Significance Determination for Wildlife and Wildlife Habitat

As discussed in Sections 7.2.10.9 to 7.2.10.12, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on wildlife and wildlife habitat indicators of high magnitude that cannot be technically or economically mitigated. Consequently, the residual environmental effects of Project construction and operations on wildlife and wildlife habitat indicators are concluded to be not significant.

7.2.11 Species at Risk

For the purpose of the assessment, species at risk are considered to include all federally-listed species of conservation concern (*i.e.*, COSEWIC or *SARA* Schedule 1 designation) (COSEWIC 2013, Environment Canada 2013c). Species identified as having the potential to occur along the proposed pipeline corridor and in the element-specific RSAs are based on previous field assessments and existing data.

This subsection discusses the species at risk that have been identified as likely to occur within each element-specific RSA. The list of federal species at risk includes 10 fish species within the Aquatics RSA, 8 vegetation species within the Vegetation RSA, and 57 wildlife species within the Wildlife RSA. Potential effects of the Project on these species are assessed through the use of indicators in Section 7.2.7 Fish and Fish Habitat, Section 7.2.9 Vegetation and Section 7.2.10 Wildlife and Wildlife Habitat.

In selecting the indicators for fish and fish habitat, vegetation and wildlife and wildlife habitat, preference was often given to species at risk. Species at risk are often sensitive to human disturbance and, as a result, are useful indicators since they provide a conservative indication of potential effects. For fish and fish habitat, species at risk identified as indicators include bull trout, Dolly Varden, Chinook salmon, coho salmon, and some populations of cutthroat trout. For vegetation, rare plant and lichen species were identified as an indicator.

For wildlife, species at risk identified as indicators for the Project include grizzly bear, woodland caribou, short-eared owl, rusty blackbird, flammulated owl, Lewis's woodpecker, Williamson's sapsucker, western screech-owl, great blue heron (*fannini* ssp.), spotted owl, common nighthawk, northern goshawk (*laingi* ssp.) and olive-sided flycatcher. In addition, many of the habitat-based communities and species groups identified as indicators included species at risk. In some cases, habitat models were developed for individual species at risk to support the assessment of these indicator communities or groups, including Pacific water shrew, western toad, Great Basin spadefoot, coastal tailed frog and western rattlesnake.

While prioritizing the selection of indicator species with conservation status, indicators were also required to reasonably represent a suite of species with similar habitat requirements, life history characteristics and most importantly, potential sensitivities to Project effects. An important consideration in selecting indicators was whether or not the indicator can be linked to a probable pathway of effect.

In cases where two or more species at risk with similar habitat requirements and life history characteristics were identified as potentially suitable indicators, the assessment considered: priority of conservation concern; the likelihood of the species to occur within the element-specific RSA; and the degree to which the species is considered to be sensitive to potential Project effects. For example, where provincially-listed species were identified with similar habitat requirements and life history characteristics to a federally-listed species, the federally-listed species was typically chosen as the indicator.

While acknowledged differences remain between species represented underneath the indicators (*e.g.*, seasonal timing in the area, preferred habitat, prey), the most important consideration remains the similarities or differences in how the potential effects of the Project manifest for a specific organism, and whether these are adequately captured by the assessment of the indicator.

Most importantly, while determinations of significance focus on the individual indicator species, mitigation is described in consideration of the broader taxonomic group or ecological guild, and will be applied to equally benefit all species at risk, not only the assessment indicators.

In summary, although not all species at risk are discussed explicitly under each indicator, potential Project effects were assessed in consideration of all species at risk. The indicators used to represent fish and fish habitat, vegetation and wildlife and wildlife habitat were carefully selected to ensure that the full range of potential Project effects on species at risk was addressed and mitigation measures to reduce these effects will apply to all species at risk, not just the indicators. Section 7.2.7 Fish and Fish Habitat, Section 7.2. Vegetation and Section 7.2.10 Wildlife and Wildlife Habitat provide the significance rationale for applicable indicator species. No significant adverse effect on species at risk has been identified as a result of the pipeline and facilities component of the Project.

7.2.12 Facilities Located Within Pipeline Right-of-Way

The elements interacting with pipeline facilities (*e.g.,* automated MLBVs) within the pipeline right-of-way and the associated potential residual effects on the environmental indicators are provided in Table 7.2.12-1. The evaluation of significance of the potential residual effects is as described in the applicable subsection of Section 7.2 for the construction and operations of the pipeline.

TABLE 7.2.12-1

POTENTIAL RESIDUAL EFFECTS ASSOCIATED WITH FACILITIES LOCATED WITHIN THE PROPOSED PIPELINE CORRIDOR

Element	Indicator	Potential Residual Effect(s)
Physical and Meteorological Environment	• N/A	• N/A
Soil and Soil Productivity	• Soil productivity	• Mixing of topsoil/root zone material and subsoil.
	• Soil degradation	• Compaction and rutting, surface erosion of topsoil/root zone material and pulverization of soil or sod.
Water Quality and Quantity	• Surface water quality	• Contamination of surface water due to a spill during construction.
	• Surface water quantity	• Localized alteration of natural drainage patterns.
Air Emissions	• CACs and VOCs	• Increase in air emissions during construction and site-specific maintenance activities.
GHG Emissions	• Emissions of CO2, CH4 and N2O • Effect on overall climate change	• Increase in GHG emissions during construction and site-specific maintenance activities. • Changes in environmental parameters (*e.g.*, increase in global average temperature)
Acoustic Environment	• Sound levels	• Increased sound levels at receptors.
Fish and Fish Habitat	• Riparian habitat	• The pipeline right-of-way crosses riparian habitat. The following potential residual effects have been identified if permanent facilities are located within riparian habitat in the pipeline right–of-way. • Riparian habitat loss or alteration due to construction activities. • Clearing of disturbance of riparian habitat during maintenance and operations.
Wetland Loss or Alteration	• Wetland function	• Loss or alteration of wetland habitat, hydrological and biogeochemical functions. • Reduction of wetland habitat, hydrological and biogeochemical functions in the event of a spill during construction.
Vegetation	• Vegetation communities of concern	• Incremental alteration of the composition of native vegetation. • Incremental alteration of grassland communities in the BG BGC Zone. • Grasslands located adjacent to the temporary facility in the BG BGC Zone may be indirectly affected by the Project. • Some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare ecological communities are located adjacent to the temporary facility they may be indirectly affected by changes in hydrology or light levels.

TABLE 7.2.12-1 Cont'd

Element	Indicator	Potential Residual Effect(s)
Vegetation (cont'd)	• Plant and lichen species of concern	• Some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare plant sub-populations are located adjacent to the temporary facility they may be affected by changes in hydrology or light levels. • Some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare lichen sub-populations are located adjacent to the temporary facility they may be affected by changes in hydrology or light levels.
	• Presence of infestations of Provincial weed species and other invasive non-native species identified as a concern	• Weed introduction and spread.
Wildlife and Wildlife Habitat	• All indicator species	• Combined effects on wildlife resulting from habitat loss or alteration, changes in movement and increased mortality risk.
Species at Risk	Refer to fish and fish habitat, vegetation and wildlife and wildlife habitat rows of this table	

7.3 Effects Assessment - Temporary Facilities Construction and Operations

The following temporary facilities that are located beyond the pipeline construction right-of-way are required during the construction of the Project:

- temporary access roads and shoo-flies;
- staging and stockpile sites;
- equipment storage sites;
- construction office sites;
- construction camps, if needed;
- trenchless crossing work areas;
- borrow pits; and
- log decks.

This subsection considers the preparation of the temporary sites and installation of temporary facilities (*i.e.,* construction) as well as the use of the temporary facilities (*i.e.,* operations). Although the need for and the respective general location of some of these sites are the responsibility of the pipeline construction contractor, all temporary facility site locations will require the approval of Trans Mountain's Inspector(s). Temporary facilities will be located within previously disturbed areas within the proposed pipeline corridor, where possible. In the event that specific mitigation is warranted for site(s), the measures developed will be documented in the Pipeline EPP prior to construction. The level of mitigation measures applied will ensure that any adverse residual environmental effects associated with the temporary facilities are reduced to a level that is not significant.

Using the assessment methodology described in Section 7.1, the following subsections evaluate the potential environmental effects associated with the construction and operations of the temporary facilities located beyond the pipeline construction right-of-way. Temporary facilities such as stockpile and staging areas that are located within the construction right-of-way are evaluated in the applicable subsection of Section 7.2. Spatial boundaries for the assessment of temporary facilities are the same as in the applicable subsection of Section 7.2 unless otherwise noted.

Environmental elements potentially interacting with the construction and operations of the temporary construction camps and other temporary facilities include:

- physical elements such as physical and meteorological environment, soil and soil productivity, water quality and quantity, air emissions, GHG emissions and acoustic environment; and
- biological elements such as fish and fish habitat, wetland loss or alteration, vegetation, wildlife and wildlife habitat, and species at risk.

7.3.1 Physical and Meteorological Environment

Sections 7.2.1.1, 7.2.1.2 and 7.2.1.3 provide the assessment indicators, measurement endpoints, spatial boundaries and physical environment context for the assessment of potential effects of the proposed temporary facilities on the physical environment.

7.3.1.1 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the construction and operations of temporary facilities such as access roads and borrow sites were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.3.1-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.1.4.

TABLE 7.3.1-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON THE PHYSICAL ENVIRONMENT

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Physical Environment Indicator – Terrain Instability				
1.1 Terrain instability	Temporary Access Roads Borrow Sites	LSA	<u>Temporary Access Roads</u> • Develop/upgrade each access road only to the extent necessary to accommodate the intended construction traffic during the period of planned use [Section 9.0]. • Where warranted and requested by the appropriate regulatory authority or private landowner, implement measures to deactivate and reclaim the access road including: - recontour the road right-of-way and replace salvaged topsoil/root zone material; - install permanent erosion control structures such as cross ditches and berms; and - seed disturbed areas with an approved cover crop and/or grass mix and, where warranted, install biodegradable erosion control measures [Section 9.0]. <u>Borrow Sites</u> • Ensure the excavation of borrow material does not extend within 1 m (minimum) of a water table [Section 11.0]. • Grade slopes created during the development or operation of upland borrow sites to stable angles (approximately 1:3; rise over run) or as specified in the applicable Pit Development Plan (to be developed and provided under separate cover) or borrow site approval conditions [Section 11.0].	• Areas of terrain instability may occur as a result of construction activities.
2. Physical Environment Indicator – Topography				
2.1 Alteration of topography	Temporary Access Roads Borrow Sites	LSA	<u>Temporary Access Roads</u> • See recommended mitigation measures outlined in potential effect 1.1 of this table. <u>Borrow Sites</u> • See recommended mitigation measures outlined in potential effect 1.1 of this table.	• Topography may be altered at borrow sites and along temporary access roads at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability.
3. Physical Environment Indicator – Acid Generating and Metal Leaching Rock				
3.1 Acid generation or metal leaching	Borrow Sites	LSA	• See recommended mitigation measures outlined in Table 7.2.1-2 Physical Environment.	• Acidification/ contamination of the terrestrial and/or aquatic environment from ARD or metal leaching.

Notes: 1 LSA = Physical Environment LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.3.1.2 Potential Residual Effects

The potential residual environmental effects on physical environment indicators associated with the construction and operations of temporary access roads and borrow sites (Table 7.3.1-1) are:

- areas of terrain instability may occur as a result of construction activities;

- topography may be altered at borrow sites and along temporary access roads at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability; and
- acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching.

7.3.1.3 Significance Evaluation of Potential Residual Effects

Table 7.3.1-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of temporary access roads and borrow sites on the physical environment. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.3.1-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON PHYSICAL ENVIRONMENT

				Temporal Context						
	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Duration	Frequency	Reversibility	Magnitude	Probability	Confidence	Significance[2]
1.	Physical Environment – Terrain Instability									
1(a)	Areas of terrain instability may occur as a result of construction activities.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low	Low	High	Not significant
2.	Physical Environment Indicator – Topography									
2(a)	Topography may be altered at borrow sites and along temporary access roads at locations where cut slopes are too steep to be replaced to the pre-construction profile without creating areas of instability.	Negative	LSA	Short-term	Isolated	Permanent	Low to medium	High	High	Not significant
3.	Physical Environment Indicator – Acid Generating and Metal Leaching Rock									
3(a)	Acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low	Low	High	Not significant

Notes: 1 LSA = Physical Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential effects on terrain instability, topography and ARD or metal leaching rock indicators was determined to be the same for the construction and operations of temporary facilities as for pipeline construction and operations (Table 7.3.1-2, points 1[a], 2[a] and 3[a]). The exception is the probability of areas of terrain instability occurring as a result of construction activities, which for temporary facilities is considered to be low due to the limited extent of ground disturbance anticipated and since temporary facilities will be located on stable, previously disturbed areas, where possible. Table 7.2.1-3 and the accompanying discussion in Section 7.2.1.6 provide an evaluation of potential residual effects of temporary facilities and their significance on the applicable physical environment indicator.

7.3.1.4 Summary

As identified in Table 7.3.1-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on physical environment indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operations of the temporary facilities on the physical environment will be not significant.

7.3.2 Soil and Soil Productivity

Sections 7.2.2.1, 7.2.2.2 and 7.2.2.3 provide the assessment indicators, measurement endpoints, spatial boundaries and soil context for the assessment of potential effects of the proposed temporary facilities on soil and soil productivity.

7.3.2.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with the construction and operations of the temporary construction camps and other temporary facilities on soil and soil productivity indicators are listed in Table 7.3.2-1. These interactions were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.3.2-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.2.4.

TABLE 7.3.2-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON SOIL AND SOIL PRODUCTIVITY

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Soil Indicator – Soil Productivity				
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Mixing of topsoil/root zone material and subsoil.
1.2 Decreased soil productivity from soil diseases (*i.e.,* clubroot disease and potato cyst nematode)	All	LSA	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Clubroot disease introduction and spread. Potato nematode introduction and spread.
2. Soil Indicator – Soil Degradation				
2.1 Degradation of soil structure due to compaction and rutting	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Degradation of soil structure and impairment of rooting zone due to compaction and rutting.
2.2 Loss of topsoil/root zone material through wind and water erosion	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.
2.3 Degradation of soil structure due to pulverization of soil and sod	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.
3. Soil Indicator – Soil Contamination				
3.1 Disturbance of previously contaminated soil	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• No residual effect identified.
3.2 Soil contamination due to spot spills during construction	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• No residual effect identified.

Notes: 1 LSA = Soils LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.3.2.2 Potential Residual Effects

The potential residual environmental effects on soil and soil productivity indicators associated with the construction and operations of the temporary construction camps and other temporary facilities (Table 7.3.2-2) are:

- mixing of topsoil/root zone material and subsoil;
- clubroot disease and potato cyst nematode introduction and spread;
- degradation of soil structure and impairment of rooting zone due to compaction and rutting;
- surface erosion of topsoil/root zone material can be expected until a vegetative cover is established; and
- pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.

Some of the potential effects on element indicators associated with the construction and operations of temporary facilities are predicted to be eliminated through the implementation of mitigation measures (Table 7.3.2-2). The potential effects determined not to have a residual effect are disturbance of previously contaminated soil and soil contamination due to spot spills during construction.

7.3.2.3 Significance Evaluation of Potential Residual Effects

Table 7.3.2-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the temporary construction camps and other temporary facilities on soil and soil productivity.

TABLE 7.3.2-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON SOIL AND SOIL PRODUCTIVITY

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Soil Indicator – Soil Productivity									
1(a) Mixing of topsoil/root zone material and subsoil.	Negative	Footprint	Short-term	Isolated	Medium-term	Low	High	High	Not significant
1(b) Clubroot disease and potato cyst nematode introduction and spread.	Negative	LSA	Short-term	Accidental	Long-term	High	Low	Moderate	Not significant
2. Soil Indicator – Soil Degradation									
2(a) Degradation of soil structure and impairment of rooting zone due to compaction and rutting.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant
2(b) Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.	Negative	Footprint	Short-term	Isolated	Medium-term	Low	High	High	Not significant
2(c) Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	Low to high	High	Not significant
2(d) Combined effects on the soil degradation indicator (2[a] to 2[c]).	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant

Notes: 1 LSA = Soil LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the soil productivity indicator and soil degradation indicator (Table 7.3.2-2 points 1[a], 1[b] and 2[a] to 2[d]) was determined to be generally the same for the construction and operations of temporary facilities as for pipeline construction and operations. The exception is the frequency of the events causing soil degradation, which for temporary facilities is confined to the construction period of the Project (*i.e.,* isolated). Table 7.2.2-3 and the accompanying discussion in Section 7.2.2.6 provide an evaluation of potential residual effects of temporary facilities and their significance on the applicable soil and soil productivity indicator.

7.3.2.4 Summary

As identified in Table 7.3.2-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on soil and soil productivity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operations of the temporary facilities on soil and soil productivity will be not significant.

7.3.3 Water Quality and Quantity

Sections 7.2.3.1, 7.2.3.2 and 7.2.3.3 provide the assessment indicators, measurement endpoints, spatial boundaries and water quality and quantity context for the assessment of potential effects of the proposed temporary facilities on water quality and quantity.

7.3.3.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with the construction and operations of the temporary construction camps and other temporary facilities on the water quality and quantity indicators listed in Table 7.3.3-1 were based on the results of the literature review, desktop analysis and the professional experience of the assessment team. Note that no interactions between temporary facilities and groundwater indicators were predicted and, consequently, no potential effects were identified.

A summary of mitigation measures provided in Table 7.3.3-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.3.4.

TABLE 7.3.3-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON WATER QUALITY AND QUANTITY

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Water Quality and Quantity Indicator – Surface Water Quality				
1.1 Possible contamination of surface water from access road runoff and grey water and sewage water discharge at temporary construction camps	Temporary AccessRoads Construction Camps	LSA	Temporary Access Roads • Do not use de-icer or salt for access road maintenance. Prevent sand used for maintenance purposes from entering watercourses by restricting sand application to access roads within 10 m of waterbodies [Section 9.0]. • Apply only water or non-toxic and non-persistent chemical products as approved to access roads for dust control [Section 9.0]. • Do not apply dust control chemicals to roads during windy conditions or within 300 m of a watercourse/wetland/lake [Section 9.0]. Construction Camps • Ensure that water withdrawal from surface water will not result in detrimental effects to the hydrologic regime [Section 10.0].	• No residual effect identified.

TABLE 7.3.3-1 Cont'd

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Possible contamination of surface water from access road runoff and grey water and sewage water discharge at temporary construction camps (cont'd)	See above	See above	• Process as required and dispose of sewage and grey water in accordance with provincial legislation and requirements [Section 10.0]. • Refer to the Water Withdrawal and Discharge Procedures Management Plan [Appendix C] for additional measures [Section 10.0]. • Follow reclamation measures outlined in the Reclamation Management Plan [Appendix C] for reclamation of sewage lagoons [Section 10.0]. <u>British Columbia</u> • Design and operate sewage facilities in accordance with the BC *Sewage Disposal Regulations* and the BC *Industrial Camp Regulations* under the *Public Health Act*. Sewage facilities in camps of more than 100 people are subject to requirements of a permit issued by the regional Health Authority [Section 10.0]. <u>Alberta</u> • Implement sewage treatment at temporary construction camps as outlined in the *Alberta Private Sewage Systems Standard of Practice* [Section 10.0].	• See above.
1.2 Suspended sediment in water column	Temporary Access Roads Borrow Sites	LSA	<u>Temporary Access Roads</u> • Align new access roads, where needed, to avoid, to the extent practical, watercourse crossings [Section 9.0]. • Align, if feasible, new access roads or extensions to existing access a minimum of 100 m from watercourses/wetlands/lakes [Section 9.0]. • Store mixtures of snow and soil in a manner that prevents sedimentation of watercourses/wetlands/lakes during spring breakup [Section 9.0]. • Install/implement drainage and erosion control measures (*e.g.,* check dams, sediment traps, culverts), as warranted, during the development of new access roads and upgrading of existing roads/trails [Section 9.0]. • Place armouring at both inflow and outflow ends of culverts, if warranted, to prevent erosion [Section 9.0]. • Provide sediment catch basins at the entrance to major culverts as deemed necessary by appropriate regulatory authorities [Section 9.0]. • Ensure ditches do not drain directly into a watercourse, unless limited by topography and approved by the appropriate regulatory authority. Install ditch blocks where required [Section 9.0]. • Apply geotechnical or bioengineering techniques, where warranted, to control chronic slumping problems that have the potential to contribute sediment to nearby watercourses to correct the problem [Section 9.0]. • Remove accumulated debris in a controlled and incremental manner to reduce the risk of flow surges, erosion and/or sedimentation of downstream areas [Section 9.0]. • Monitor and, if warranted, repair erosion control measures and/or implement supplemental erosion control measures, when the risk of erosion and sedimentation of a watercourse exists [Section 9.0].	• Reduction in surface water quality due to suspended sediment during construction and operations of temporary access roads and borrow sites.

TABLE 7.3.3-1 Cont'd

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.2 Suspended sediment in water column (cont'd)	Temporary Access Roads Borrow Sites	LSA	• See also Section 7.2.3 Water Quality and Quantity for additional measures. Borrow Sites • Create retention ponds, where warranted, using the BC *Dam Safety Review Guidelines*, *Canadian Dam Safety Guidelines*, *Stormwater Management Guidelines* for the Province of Alberta, and *Aggregate Operators Best Management Practices Handbook for British Columbia* as a guide to hold sediment laden stormwater runoff until the sediment has settled [Section 11.0]. • Conduct discharge of water from retention ponds as outlined in the Water Withdrawal and Discharge Procedures Management Plan [Appendix C]. • Follow all approval conditions related to the withdrawal or discharge of water associated with the operation of borrow sites [Section 11.0]. • Discharge water from a settling pond, retention pond or other stormwater site onto the borrow site if feasible. Avoid discharging this water into a watercourse/wetland/lake without the approval of the Inspector(s) and acquisition of applicable approvals [Section 11.0]. • Follow water quality guidelines and additional measures for the discharge of water at borrow sites as outlined in the Water Quality Management Plan [Appendix C].	• See above.
1.3 Reduction of surface water quality due to small spill during construction	Temporary Access Roads Borrow Sites Other Temporary Sites	LSA	• See recommended mitigation measures outlined in Table 7.2.3-2 Water Quality and Quantity.	• Contamination of surface water due to a small spill during construction.
2. Water Quality and Quantity Indicator – Surface Water Quantity				
2.1 Localized alteration of natural surface drainage patterns during construction and operations of the temporary access roads, borrow sites and other temporary sites	Temporary access roads Borrow sites Other temporary sites	LSA	Temporary Access Roads • Ensure adequate drainage by maintaining the proper grade and installing culverts to allow for cross drainage. Outslope the crown of the road so that it is a minimum of 15 cm higher than the shoulders to allow the road surface to drain and dry [Section 9.0]. • Ensure that culverts of proper size, number and alignment are in place to handle peak run-off events for the period/duration the culverts will be in place and to reduce water movement along ditches and road surface [Section 9.0]. • Reduce alteration of natural drainage patterns by aligning culverts with the drainage and at angles other than right angles to the road [Section 9.0]. • Remove accumulated debris in a controlled and incremental manner to reduce the risk of flow surges [Section 9.0]. • Monitor the effectiveness of culverts in handling surface drainage across temporary access roads following installation [Section 9.0]. • Remove and reclaim new temporary access roads developed for the Project unless otherwise directed by the appropriate regulatory authority or landowner [Section 9.0]. Follow reclamation measures outlined in the Reclamation Management Plan [Appendix C].	• Localized alteration of natural surface drainage patterns.

TABLE 7.3.3-1 Cont'd

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.1 Localized alteration of natural surface drainage patterns during construction and operations of the temporary access roads, borrow sites and other temporary sites (cont'd)	Temporary access roads Borrow sites Other temporary sites	LSA	<u>Borrow Sites</u> • Grade borrow sites, where feasible, to maintain natural surface drainage or drainage structures. Install/construct ditches or berms to provide surface drainage and direct stormwater around the borrow site [Section 11.0]. • Remove the dykes of settling and retention ponds, if present, and recontour the area. Remove or rip clay liners to restore natural drainage [Section 11.0]. • Seed and revegetate borrow sites to be restored in accordance with the respective Pit Development Plan (to be developed and provided under separate cover) and Reclamation Management Plan [Appendix C] [Section 11.0]. <u>Other Temporary Facilities</u> • Ensure that selected sites for temporary construction camps and staging areas are outside of applicable riparian buffers [Section 10.0]. • Ensure that selected sites for camps and staging areas are above the highest annual flood level (200-year flood), where practical [Section 10.0]. • Inspect all water conveyance installations (*e.g.,* ditches and culverts) and ensure they are functioning appropriately. Take appropriate action prior to and during the spring freshet to clear culverts blocked by ice or debris [Section 7.0]. • Maintain or, when the area is stabilized, remove drainage and erosion control devices and materials at all sites that are no longer in use [Section 7.0]. • Follow reclamation measures outlined in the Reclamation Management Plan [Appendix C] for reclamation of temporary construction sites [Section 10.0].	• See above.

Notes: 1 LSA = Water Quality and Quantity LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.3.3.2 Potential Residual Effects

The potential residual environmental effects on water quality and quantity indicators associated with the construction and operations of the temporary construction camps and other temporary facilities (Table 7.3.3-1) are:

- reduction in surface water quality due to suspended sediment during construction and operations of temporary access roads and borrow sites;
- contamination of surface water due to a small spill during construction; and
- localized alteration of natural surface drainage patterns.

Some of the potential effects on water quality and quantity indicators associated with the construction and operations of temporary facilities are predicted to be eliminated through the implementation of mitigation measures (Table 7.3.3-1). The potential effects determined not to have a residual effect are contamination of surface water from access road runoff and grey water and sewage water discharge at temporary construction camps.

7.3.3.3 Significance Evaluation of Potential Residual Effects

Table 7.3.3-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of temporary construction camps and other temporary facilities on water quality and quantity indicators.

TABLE 7.3.3-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON WATER QUALITY AND QUANTITY

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Water Quality and Quantity Indicator – Surface Water Quality									
1(a)	Reduction in surface water quality due to suspended sediment during construction and operations of temporary access roads and borrow sites.	Negative	LSA	Immediate to short-term	Isolated	Immediate to short-term	Low	High	High	Not significant
1(b)	Contamination of surface water due to a small spill during construction.	Negative	LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
2.	Water Quality and Quantity Indicator – Surface Water Quantity									
2(a)	Localized alteration of natural surface drainage patterns.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low to medium	High	High	Not significant

Notes: 1 LSA = Water Quality and Quantity LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the surface water quality indicator and the surface water quantity indicator (Table 7.3.3-2, point 1[a], 1[b] and 2[a]) was determined to be generally the same for the construction and operations of temporary facilities as for pipeline construction and operations. The exception is the frequency of events causing reduced surface water quality and localized alteration of drainage patterns, which for temporary facilities is confined to the construction period of the Project (*i.e.,* isolated). Table 7.2.3-3 and the accompanying discussion in Section 7.2.3.6 provide an evaluation of potential residual effects of temporary facilities and their significance on the applicable water quality and quantity indicator.

7.3.3.4 Summary

As identified in Table 7.3.3-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on water quality and quantity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operations of the temporary facilities on water quality and quantity will be not significant.

7.3.4 Air Emissions

Sections 7.2.4.1 and 7.2.4.2 provide the assessment indicator, measurement endpoints and spatial boundaries for the assessment of potential effects of the proposed temporary facilities on air emissions.

7.3.4.1 Project Associated Air Emissions

During the construction of temporary facilities, site preparation, operation of vehicles and equipment, and other construction activities will result in air emissions. It is assumed that no burning of slash will be required for the construction of temporary facilities. During operation of the temporary facilities, air emissions are caused by transportation and activities associated with the residence of workers (*e.g.,* space heating and electricity use in construction camps). All air emissions associated with construction and operation of temporary facilities will be intermittent and limited in duration to the construction phase of the Project.

Information on construction and operations activities for temporary facilities was not separated from construction activities for permanent facilities and pipelines. Therefore, air emissions associated with construction and operations activities for temporary facilities are estimated as part of the total construction-related emissions for the pipeline as provided in Section 7.2.4.3.

7.3.4.2 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects on the air emissions indicator that are associated with the construction and operation of temporary construction camps and other temporary facilities are listed in Table 7.3.4-1. These interactions were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of the mitigation measures as provided in Table 7.3.4-1 was principally developed in accordance with Trans Mountain standards and accepted construction methods for temporary facility construction-related activities.

TABLE 7.3.4-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON AIR EMISSIONS

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds				
1.1 Project contribution to emissions	All	RSA	• See recommended mitigation measures outlined in Table 7.2.4-3 Air Emissions. • Ensure that borrow site activities adhere to local air bylaws unless otherwise approved by municipal authorities.	• Increase in air emissions during construction of temporary facilities.
1.2 Dust during construction	Temporary access roads Staging and stockpile sites Borrow sites	RSA	• Trans Mountain will consult with and inform landowners with the potential to be affected by dust emissions from construction activities prior to commencement of these activities in proximity to the respective landowners [Section 8.2]. • When warranted, spray water on access roads, material storage piles, and work areas within borrow sites to minimize dust emissions. Install dust skirts on stockpiling and loading equipment to limit dust emissions where the potential for generation of large quantities of fugitive dust exists [Section 11.0]. • During stockpiling and loading at borrow sites, the drop height will be limited to reduce or avoid the potential for dust generation. The contractor will ensure that dump truck loads are covered prior to travelling on public roads and gate seals are kept tight on dump trucks [Section 11.0]. • Reduce the backhoe bucket drop height during stockpiling and loading of soils and aggregate to limit the potential for noise and dust emissions [Section 10.0].	• Increase in fugitive dust during construction of temporary facilities.

Notes: 1 RSA = Air Quality RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.3.4.3 Potential Residual Effects

The potential residual environmental effects on the air emissions indicator associated with the construction and operation of the temporary construction camps and other temporary facilities (Table 7.3.4-1) are:

- an increase in air emissions during construction of temporary facilities; and
- an increase in fugitive dust during construction of temporary facilities.

7.3.4.4 Significance Evaluation of Potential Residual Effects

Where there are no standards, guidelines, objectives or other established and accepted thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method is considered to be the appropriate method for determining the significance of the anticipated residual environmental effects. Consequently, a qualitative assessment of air emissions was determined to be the most appropriate method where the evaluation of significance of each of the potential residual effects relies on the professional judgment of the assessment team.

Table 7.3.4-2 provides a summary of the significance evaluation of the potential residual environmental effects on air emissions from the construction and operation of the temporary construction camps and other temporary facilities.

TABLE 7.3.4-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON AIR EMISSIONS

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
1.	Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds									
1(a)	Increase in air emissions during construction.	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant
1(b)	Increase in fugitive dust during construction.	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant
1(c)	Combined effects on the primary emissions of CACs and VOCs indicator (1[a] and 1[b]).	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant

Notes: 1 RSA = Air Quality RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the primary emissions of CACs and VOCs indicator (Table 7.3.4-2, points 1[a] to 1[c]) was determined to be the same for the construction and operations of temporary facilities as for pipeline construction and operations. The evaluation of potential residual effects in and their significance on the primary emissions of CACs and VOCs indicator in Table 7.2.4-4, points 1[a], [c], and [d], and the accompanying discussion in Section 7.2.4.6 is also applicable temporary facilities.

7.3.4.5 Summary

As identified in Table 7.3.4-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the air emissions indicator of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operation of the temporary facilities on air emissions will be not significant.

7.3.5 Greenhouse Gas Emissions

As discussed in Section 7.2.5.3, during the construction of temporary facilities, site preparation, operation of vehicles and equipment, and other construction activities will result in GHG emissions. During operation of the temporary facilities, GHG emissions are caused by transportation and activities associated with the residence of workers (*e.g.,* space heating and electricity use). All GHG emissions associated with construction and operation of temporary facilities will be intermittent and limited in duration to the construction phase of the Project.

The assessment of effects on GHG emissions has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, Westridge Marine Terminal and pipeline reactivation), since GHG emissions associated with the construction and operation of each Project component are aggregated for the Project as a whole and then compared to provincial and federal GHG inventory totals.

The assessment of effects on GHG emissions for the Project as a whole is presented in Section 7.2.5. Table 7.2.5-8 and accompanying discussion in Section 7.2.5.3 provide an evaluation of potential residual effects of temporary facilities on GHG indicators.

7.3.6 Acoustic Environment

Sections 7.2.6.1, 7.2.6.2 and 7.2.6.3 provide the assessment indicators, measurement endpoints, spatial boundaries and acoustic environment context for the assessment of potential effects of the proposed temporary facilities on acoustic environment.

7.3.6.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential environmental effects associated with the construction and operations of the temporary construction camps and other temporary facilities, as well as the proposed mitigation measures and resulting potential residual effects, are listed in Table 7.3.6-1. These potential effects were based on the results of the literature review, desktop analysis and the professional experience of the assessment team. Note that no interactions between temporary facilities and the vibration indicator were predicted and, consequently, no potential effects were identified.

A summary of mitigation measures provided in Table 7.3.6-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.6.4.

TABLE 7.3.6-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON THE ACOUSTIC ENVIRONMENT

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Acoustic Environment Indicator – Sound Levels				
1.1 Changes in sound levels during construction and operations of the temporary facilities	All	LSA	• See recommended mitigation measures in Table 7.2.6-2 Acoustic Environment.	• Increase in sound levels associated with temporary facilities during the construction period of the Project.

Notes: 1 LSA = Acoustic Environment LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.3.6.2 Residual Effects

The potential residual environmental effects on the acoustic environment indicator associated with the construction and operations of the temporary construction camps and other temporary facilities (Table 7.3.6-1) include increase in sound levels during the construction period of the Project.

7.3.6.3 Significance of Residual Effects

Table 7.3.6-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of temporary construction camps and other temporary facilities on the acoustic environment indicator.

TABLE 7.3.6-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON THE ACOUSTIC ENVIRONMENT

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Acoustic Environment Indicator – Sound Levels									
1(a) Increase in sound levels associated with temporary facilities during the construction period of the Project.	Negative	LSA	Short-term	Isolated	Short-term	Low to medium	High	Moderate	Not significant

Notes: 1 LSA = Acoustic Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

It is anticipated that the increase in sound levels due to the construction and operations of the temporary facilities during the construction period of the Project (Table 7.3.6-2, point 1[a]) will be similar to the sound levels generated by the construction of the proposed pipeline. The sound levels associated with the use of the temporary facilities during pipeline construction is expected to be less than those associated with the construction of the pipeline itself. Details on the residual effects associated with the pipeline construction are described in detail in Section 7.2.6.6.

7.3.6.4 Summary

As identified in Table 7.3.6-2, there are no situations with respect to the construction and operations of the temporary facilities where there is a high probability of occurrence of a permanent or long-term residual environmental effect on acoustic environment indicators of high magnitude. Consequently, is it concluded that the residual environmental effects of construction and operations of the temporary facilities on the acoustic environment will be not significant.

7.3.7 Fish and Fish Habitat

Temporary facilities may interact with fish and fish habitat indicators through the construction of temporary access roads and vehicle crossings, which may lead to increased sedimentation in watercourses. This can cause an alteration to instream habitat and may lead to fish mortality and injury. The construction of temporary access roads may also result in increased access to watercourses, which may affect riparian habitat, instream habitat and may lead to fish mortality and injury as a result of recreational fishing pressures.

The assessment of effects on fish and fish habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks and pipeline reactivation), since the components will have similar effect pathways (*i.e.,* riparian habitat, instream habitat and fish mortality and injury) on fish indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for fish indicators.

The assessment of effects on fish and fish habitat for the Project as a whole is presented in Section 7.2.7. Table 7.2.7-3 and accompanying discussion in Section 7.2.7.6 provide an evaluation of potential residual effects of temporary facilities on fish indicators.

7.3.8 Wetland Loss or Alteration

Sections 7.2.8.1, 7.2.8.2 and 7.2.8.3 provide the assessment indicators, measurement endpoints, spatial boundaries and ecological context for the assessment of potential effects of the proposed temporary facilities on wetland loss or alteration.

7.3.8.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Although the need for and the respective general location of some of these sites are the responsibility of the pipeline construction contractor, all temporary facility site locations will require the approval of Trans Mountain's Inspector(s). Although unlikely, there is the potential for wetlands to be affected by one or more of these facilities.

Potential effects associated with the construction and operations of the proposed temporary facilities on the wetland indicator are listed in Table 7.3.8-1. These interactions are based on the results of the literature review, available research literature desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.2.8-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines learnings from wetland post-construction environmental monitoring for previous projects and peer-reviewed publications on wetland function as described in Section 7.2.8.4.

TABLE 7.3.8-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON WETLAND LOSS OR ALTERATION

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Wetland Loss or Alteration Indicator – Wetland Function				
1.1 Potential loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.,* habitat, hydrology, biogeochemistry)	All	LSA	• See recommended mitigation measures outlined in Table 7.2.8-2 Wetland Loss or Alteration.	• Alteration of wetland habitat, hydrological and biogeochemical function from the facilities during construction activities until vegetation is re-established and sedimentation is controlled.
1.2 Potential contamination of wetland function (*i.e.,* habitat, hydrology, biogeochemistry) due to a spill during construction	All	LSA	• See recommended mitigation measures outlined in Table 7.2.8-2 Wetland Loss or Alteration.	• Reduction of wetland habitat, hydrological and biogeochemical function in the event of a spill from stored equipment during construction (depending on the volume and type of substance spilled).

Note: 1 LSA = Wetland LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.3.8.2 Potential Residual Effects

The potential residual environmental effects on the wetland indicator associated with the construction and operations of the temporary facilities (Table 7.3.8-1) are:

- alteration of wetland function (*i.e.,* habitat, hydrological, biogeochemical) from temporary facilities during construction until vegetation is re-established, grade and natural flow patterns are restored and until sedimentation is controlled; and
- reduction of wetland habitat, hydrological and biogeochemical function in the event of a spill from stored equipment during construction (depending on the volume and type of substance spilled).

7.3.8.3 Significance Evaluation of Potential Residual Effects

Table 7.3.8-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of temporary facilities on the wetland indicator.

TABLE 7.3.8-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON WETLAND LOSS OR ALTERATION

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Wetland Loss or Alteration Indicator – Wetland Function									
1(a)	Alteration of wetland habitat, hydrological and biogeochemical functions during construction activities until vegetation is re-established, grade and natural flow patterns are restored and sedimentation is controlled.	Negative	LSA	Short -term	Isolated	Medium to long-term	Low	High	High	Not significant
1(b)	Reduction of wetland habitat, hydrological and biogeochemical functions in the event of a spill from stored equipment during construction.	Negative	LSA	Immediate	Accidental	Short to long-term	Low to high	Low	High	Not significant

Notes: 1 LSA = Wetland LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the wetland function indicator was determined to be generally the same for the construction and operations of temporary facilities as for pipeline construction and operations (Table 7.3.8-2, points 1[a] and 1[b]). The exception is the frequency of the event causing alteration of wetland habitat, hydrological and biogeochemical function which for temporary facilities is limited to the construction period of the Project (*i.e.,* isolated). Table 7.2.8-4 and the accompanying discussion in Section 7.2.8.6 provide an evaluation of significance of the potential residual effects of the construction of temporary facilities on wetland loss or alteration.

7.3.8.4 Summary

As identified in Table 7.3.8-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the wetland indicator of high magnitude that cannot be technically or economically mitigated. Consequently, is it concluded that the residual environmental effects of construction and operations of the temporary facilities on wetland loss or alteration will be not significant.

7.3.9 Vegetation

Sections 7.2.9.1, 7.2.9.2 and 7.2.9.3 provide the assessment indicators, measurement endpoints, spatial boundaries and ecological context for the assessment of potential effects of the proposed temporary facilities on vegetation.

7.3.9.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Although the need for and the respective general location of some of these sites are the responsibility of the pipeline construction contractor, all temporary facility site locations will require the approval of Trans Mountain's Inspector(s). It is assumed that temporary facilities will be located within previously disturbed areas and, consequently, the probability of temporary facilities affecting rare ecological communities or plant and lichen species of concern are low. However, should it be determined that temporary facilities may affect native vegetation with potential for rare ecological communities or plant and lichen species of concern, the mitigation measures from the Rare Ecological Community and Rare Plant Population Management Plan (Volume 6B) will be implemented as appropriate.

Potential effects associated with the construction and operations of the proposed temporary facilities on vegetation are listed in Table 7.3.9-1. These interactions are based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.3.9-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.9.4.

TABLE 7.3.9-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON VEGETATION

Potential Effect	Temporary Facility Type	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Vegetation Indicator – Vegetation Communities of Concern				
1.1 Alteration of native vegetation	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.9-3 Vegetation.	• Incremental alteration of the composition of native vegetation.
1.2 Alteration of grasslands in the BG BGC Zone	Temporary facilities in Kamloops area	LSA	• See recommended mitigation measures outlined in Table 7.2.9-3 Vegetation.	• Some disturbance or alteration of grassland communities in the BG BGC Zone.
2. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern				
2.1 Weed introduction and spread	All	RSA	• See recommended mitigation measures outlined in Table 7.2.9-3 Vegetation.	• Weed introduction and spread.

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.3.9.2 Potential Residual Effects

The potential residual environmental effects on vegetation indicators associated with the construction and operations of the temporary facilities (Table 7.3.9-1) are:

- incremental alteration of the composition of native vegetation;
- some disturbance or alteration of grassland communities in the BG BGC Zone; and
- weed introduction and spread.

7.3.9.3 Significance Evaluation of Potential Residual Effects

Table 7.3.9-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of temporary facilities on vegetation indicators.

TABLE 7.3.9-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF TEMPORARY FACILITIES ON VEGETATION

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Vegetation Indicator – Vegetation Communities of Concern									
1(a) Incremental alteration of the composition of native vegetation.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Low to medium	High	Moderate	Not significant

TABLE 7.3.9-2 Cont'd

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
1(b) Some disturbance or alteration of grassland communities in the BG BGC Zone.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Low to medium	Low	Moderate	Not significant
2. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-native Species Identified as a Concern									
2(a) Weed introduction and spread.	Negative	RSA	Short-term	Isolated	Short to medium-term	Low to medium	High	High	Not significant

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the vegetation communities of concern indicator and the presence of infestations of Provincial weed species and other invasive non-native species identified as a concern indicator (Table 7.3.9-2, points 1[a], 1[b] and 2[a]) was determined to be generally the same for the construction and operations of temporary facilities as for pipeline construction and operations. There are two exceptions: the frequency of the event causing the residual effects for the vegetation communities of concern indicator which for temporary facilities, is confined to the construction period of the Project (*i.e.,* isolated); and the probability of some disturbance or alteration of grassland communities in the BG BGC Zone is low due to the expected placement of the temporary facilities. Table 7.2.9-3 and the accompanying discussion in Section 7.2.9.6 provide an evaluation of potential residual effects of temporary facilities and their significance on the applicable vegetation indicator.

7.3.9.4 Summary

As identified in Table 7.3.9-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the vegetation indicators of high magnitude that cannot be technically or economically mitigated. Consequently, is it concluded that the residual environmental effects of the construction and operations of the temporary facilities on vegetation will be not significant.

7.3.10 Wildlife and Wildlife Habitat

The assessment of effects on wildlife and wildlife habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, other ancillary facilities, and the Westridge Marine Terminal), since the components will have similar effect pathways (*i.e.,* change in habitat movement and mortality risk) on wildlife indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for wildlife indicators.

The assessment of effects on wildlife and wildlife habitat for the Project as a whole is presented in Section 7.2.10. Table 7.2.10-6 and accompanying discussion in Section 7.2.10.9 provide the evaluation of potential residual effects of temporary facilities on mammal indicators, Table 7.2.10-9 and accompanying discussion in Section 7.2.10.10 provide the evaluation of potential residual effects of temporary facilities on bird indicators, Table 7.2.10-12 and accompanying discussion in Section 7.2.10.11 provide the evaluation of potential residual effects of temporary facilities on amphibian indicators, and Table 7.2.10-15 and accompanying discussion in Section 7.2.10.12 provide the evaluation of potential residual effects of temporary facilities on the reptile indicator.

7.3.11 Species at Risk

The assessment indicators for fish, vegetation and wildlife and wildlife habitat include species at risk that may be affected by Project activities. Sections 7.3.7, 7.3.9 and 7.3.10 provide the effects assessment of construction and operations of temporary facilities on species at risk for fish, vegetation and wildlife, respectively.

7.4 Effects Assessment – Pump Stations

To accommodate the expansion, the Project will include construction and operations of new pump stations serving the new pipeline at 10 of the existing pump station sites at Edmonton, Gainford, Wolf, Edson and Hinton in Alberta, and at Rearguard, Blue River, Blackpool, Kamloops and Kingsvale in BC. Two new pump stations will also be constructed and operated at a new greenfield site at Black Pines, BC. In addition, the Project also involves expansion, replacement, reactivation and deactivation of pump stations and pump buildings as well as other associated components such as access roads and power lines. Table 7.4-1 describes the activities to be conducted at each pump station facility and whether new lands outside of the existing facility are required.

TABLE 7.4-1

PROJECT ACTIVITIES TO BE CONDUCTED AT PUMP STATION FACILITIES

Pump Station Facility	New Pump Units	Deactivation/ Reactivation	Disturbance of Previously Undisturbed Areas within Existing Fenceline	New Lands Outside of Existing Fenceline	Other Activities
Edmonton, AB	4 x 5,000 HP 1 spare 5,000 HP	No	No	No	• New scraper facilities (sending) on TMEP • New substation • New power line (to be determined by provincial regulatory authority) • Fencing
Gainford, AB	3 x 5,000 HP	No	Yes (forested lands outside existing fenceline but within existing property boundary)	No	• Upgrades to existing substation • Fencing
Niton, AB	No	Reactivation of 2 x 5,000 HP pump units	No	No	• None
Wolf, AB	2 X 5,000 HP	Deactivation	No	No	• Existing pump building will be deactivated • Fencing
Edson, AB	3 x 5,000 HP	No	No	No	• New scraper facilities (sending and receiving) on TMEP • Replace existing substation • New power line (to be determined by provincial regulatory authority) • Fencing and on-site gravel road
Hinton, AB	3 x 5,000 HP	No	No	Yes (0.3 ha of forested lands)	• New scraper facilities (sending) on TMPL • Fencing
Jasper, AB	No	No	No	No	• Relocate two existing 2,500 HP pumps from the TMX Anchor Loop pipeline to TMPL (currently deactivated) • Drag resistant agent injection facility requiring a small storage tank (with secondary containment) and high pressure injection pump
Rearguard, BC	2 x 5,000 HP	No	No	Yes (0.7 ha of disturbed lands)	• Remove scraper facilities (sending and receiving) from Hargreaves • New scraper facilities (sending and receiving) on TMPL and TMEP • Fencing and on-site gravel road
Blue River, BC	3 x 5,000 HP	Deactivation	No	No	• Existing pump building will be deactivated
Blackpool, BC	3 x 5,000 HP	No	No	No	• Upgrade existing transformer • Fencing and on-site gravel road
Darfield, BC	No	No	No	Yes (0.07 ha of agricultural land)	• New scraper facilities (receiving) on TMEP • Fencing

TABLE 7.4-1 Cont'd

Pump Station Facility	New Pump Units	Deactivation/ Reactivation	Disturbance of Previously Undisturbed Areas within Existing Fenceline	New Lands Outside of Existing Fenceline	Other Activities
Black Pines, BC	2 x 2,500 HP 2 x 5,000 HP	No	No	Yes – new facility site on forested lands (2.3 ha)	• New substation to serve both lines • New scraper facilities (sending and receiving) on TMPL and TMEP • New access road approximately 5 m x 25 m • New 138 kV power line approximately 50 m x 2.2 km • Fencing and on-site gravel road
Kamloops, BC	3 x 5,000 HP 1 spare 5,000 HP	No	No	No	• New substation to serve TMEP • New scraper facilities (sending and receiving) on TMEP
Kingsvale, BC	2 x 5,000 HP	No	Yes (forested)	No	• Replace existing substation • New 138 kV power line approximately 50 m x 23.5 km • Fencing
Sumas, BC	1 x 2,500 HP serving the Puget Sound line	No	No	No	• Upgrade existing substation
Total Number of New Pump Units: 35					

A detailed description of the Project activities at pump station facilities is provided in Section 2.0 of this volume and in Volume 2.

Using the assessment methodology described in Section 7.1, the following subsections evaluate the potential environmental effects arising from the Project activities at pump stations (including construction and operations of new pump units and a new pump station facility, associated power lines, and reactivation of existing pump stations).

Environmental elements potentially interacting with the Project activities at pump station facilities are identified in Table 7.4-2. The table also describes the rationale for those environmental elements which are not considered to interact with the Project activities at pump station facilities. Spatial boundaries for the assessment of pump station facilities are the same as in the applicable subsection of Section 7.2 unless otherwise noted.

TABLE 7.4-2

ELEMENT INTERACTION WITH PROJECT ACTIVITIES AT PUMP STATION FACILITIES

Element	Interaction with Pump Station Component		
	Construction	Operations[1]	Reactivation
Physical and Meteorological Environment	Yes	Yes	No – physical environment will not be disturbed as a result of reactivation activities
Soil and Soil Productivity	Yes	Yes	No – soil will not be disturbed as a result of reactivation activities
Water Quality and Quantity	Yes	Yes	No – reactivation activities are not expected to affect water quality or quantity
Air Emissions	Yes	Yes	Yes
GHG Emissions	Yes	Yes	Yes
Acoustic Environment	Yes	Yes	Yes
Fish and Fish Habitat	Yes	Yes	No – reactivation activities are not expected to affect fish or fish habitat
Wetland Loss or Alteration	Yes	No – pump station operations is not expected to impact wetlands	No – reactivation activities are not expected to affect wetlands
Vegetation	Yes	Yes	No – reactivation activities are not expected to affect vegetation
Wildlife and Wildlife Habitat	Yes	Yes	No – reactivation activities are not expected to affect wildlife and wildlife habitat
Species at Risk	Yes	Yes	No – reactivation activities are not expected to affect species at risk

Note: 1 Activities during operations include maintenance activities and vegetation management (*e.g.,* weed control).

7.4.1 Physical and Meteorological Environment

Sections 7.2.1.1 and 7.2.1.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of Project activities at pump station facilities on the physical environment.

7.4.1.1 Physical Environment Context

Considerable grading may be required at Black Pines, Kingsvale and Kamloops pump stations and along the proposed operations access road to Black Pines Pump Station. No considerable grading is anticipated for construction of the proposed 2.2 km power line extending to Black Pines Pump Station and the proposed 23.5 km power line extending to Kingsvale Pump Station.

7.4.1.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the construction and operations of pump stations, power lines and the operations access road were based on the results of the literature review, desktop analysis, engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team. Potential effects associated with physical environment indicators that are not anticipated to result from Project activities at pump stations are: terrain instability at watercourses; alteration of topography from blasting; and acid generation or metal leaching. Furthermore, through proper pole placement and installation, no terrain instability or alteration in topography is anticipated along the power lines.

A summary of mitigation measures provided in Table 7.4.1-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.1.4.

TABLE 7.4.1-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON PHYSICAL ENVIRONMENT

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Physical Environment Indicator – Terrain Instability				
1.1 Terrain instability	Black Pines Pump station Access road Kamloops Kingsvale Pump station	LSA	Pump Stations • Retain vegetation mat outside of the development zone if a competent vegetation mat layer exists, if feasible. In these areas, grade only within the development zone in order to reduce disturbance to the vegetation mat. Grading of the vegetation mat layer will not be permitted on level terrain in these areas [Section 8.2]. • Grade the surface to facilitate water drainage into water conveyance features (*e.g.,* ditches and culverts) [Section 8.2]. • Assess the erosion hazard prior to the commencement of rough and final clean-up. This assessment, to be conducted by the Inspector, in consultation with the Construction Manager, will consider topography, degree of disturbance, soil erodibility, snow depth, access limitations, timing constraints, and the likely schedule for rough clean-up, final clean-up and seeding. Request assistance in conducting the assessment, if warranted, from the Environmental Manager, or the Geotechnical, Soil or Reclamation Resource Specialist [Section 8.4]. Operations Access Roads • Develop/upgrade each access road only to the extent necessary to accommodate the intended construction traffic during the period of planned use [Section 9.0]. • Provide adequate spillways for culverts in unstable areas or where road-fill materials are unprotected [Section 9.0]. • Maintain all side cuts in roads in a stabilized and revegetated condition, to the extent feasible. Apply geotechnical or bioengineering techniques, where warranted, to control chronic slumping problems [Section 9.0].	• No residual effect identified.
2. Physical Environment Indicator – Topography				
2.1 Alteration of topography	Black Pines Pump station Access road Kamloops Kingsvale Pump station	LSA	Pump Stations • Ensure that there is no grading beyond the stakes unless additional workspace rights have been obtained. Grade only those areas essential for construction [Section 8.2]. • Ensure graded material does not spread off-site [Section 8.2]. • Recontour areas disturbed during facility construction outside of the development zone to pre-construction contours (where feasible) and drainage channels if frozen soil conditions prevented completion of this task during facility construction [Section 8.4]. • Regrade areas with vehicle ruts and erosion features [Section 8.4]. • Dispose of excess rock displaced from excavation at an approved location as determined by the Inspector or the appropriate regulatory authority [Section 8.4]. Operations Access Roads • See recommended mitigation measures outlined in potential effect 1.1 of this table.	• Alteration of topography at pump stations and the operations access road where grading is required.

Notes: 1 LSA = Physical Environment LSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.4.1.3 Potential Residual Effects

The potential residual environmental effect on physical environment indicators associated with Project activities at pump station facilities is alteration of topography at pump stations and the operations access road where grading is required (Table 7.4.1-1).

Potential terrain instability resulting from construction and operations of pump stations and the operations access road is concluded not to have a residual effect because instability potential is predicted to be eliminated through the implementation of mitigation measures (Table 7.4.1-1).

7.4.1.4 Significance Evaluation of Potential Residual Effects

Table 7.4.1-2 provides a summary of the significance evaluation of the potential residual environmental effects on physical environment indicators resulting from Project activities at pump station facilities. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.4.1-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON PHYSICAL ENVIRONMENT

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Physical Environment Indicator – Topography									
1(a)	Alteration of topography at pump stations and the operations access road where grading is required.	Negative	Footprint	Short-term	Isolated	Permanent	Low	High	High	Not significant

Notes: 1 LSA = Physical Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Alteration of Topography Where Grading is Required

As a result of construction, topography may be altered at locations where considerable grading is required to obtain a level profile at pump stations. Grading will vary from only topsoil salvaging in some areas to extensive cuts and fills in other areas. Any bedrock encountered will be ripped mechanically using bulldozers and excavators. Following construction, areas disturbed during facility construction outside of the fenced area of the site will be recontoured to pre-construction contours where feasible.

The impact balance of this residual effect is considered negative since local topographic alteration is considered a detriment to the environment. Although this unavoidable consequence is considered to be permanent and of high probability, magnitude is considered to be low (Table 7.4.1-2, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – alterations in topography will be limited to the construction workspace.
- Duration: short-term – the event causing the alterations in topography is construction of the pump stations and access road.
- Frequency: isolated – the event causing the alteration in topography is construction of the pump stations and access road.
- Reversibility: permanent – alterations in topography resulting from levelling of terrain at pump stations will not be reversed (*i.e.,* pre-construction contours will not fully be restored during decommissioning and abandonment).
- Magnitude: low – the extent of alteration of topography at pump stations is considered low due to the limited extent of grading required and because the most extensive grading will take place at existing pump station sites designated for industrial use.
- Probability: high – based on data pertinent to the Project area and the professional experience of the assessment team.

- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

7.4.1.5 Summary

As identified in Table 7.4.1-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on physical environment indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with Project activities at pump station facilities on the physical environment will be not significant.

7.4.2 Soil and Soil Productivity

Sections 7.2.2.1 and 7.2.2.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of Project activities at pump station facilities on soil and soil productivity.

7.4.2.1 Soil Context

Disturbance to soils is expected at the Gainford Pump Station, Hinton Pump Station, Rearguard Pump Station, Darfield Pump Station and Kingsvale Pump Station and associated power line, as well as at the proposed Black Pines Pump Station and associated power line. Section 7.2.2.3 provides additional context on soils.

7.4.2.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the Project activities at pump station facilities on soil and soil productivity indicators are listed in Table 7.4.2-1. These interactions were based on the results of the literature review, desktop analysis, field work, engagement with landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.4.2-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.2.4.

TABLE 7.4.2-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON SOIL AND SOIL PRODUCTIVITY

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Soil Indicator – Soil Productivity				
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging	Gainford Hinton Rearguard Darfield Black Pines Pump station Access road Power line Kingsvale Power line	Footprint	<u>Facilities</u> • Salvage topsoil/root zone material from the development zone and areas to be graded within the facility footprint that will be disturbed during construction (see Drawing [Pump Station Construction – Topsoil/Root Zone Material Salvage] provided in Appendix R) [Section 8.2]. • Salvage all available topsoil/root zone material (minimum 15 cm or 50% organic material) using the Environmental Facility Drawings as a guide, unless the material is unsuitable (*e.g.,* bedrock, gravel, rock) [Section 8.2]. See additional measures under Section 8.2 of the Facilities EPP. • Salvage very deep surface soils to a maximum depth of 70 cm, if encountered [Section 8.2]. • Salvage very shallow surface soils to a minimum depth of 15 cm. If minimum depth of surface soils cannot be salvaged because the underlying material is unsuitable (*e.g.,* bedrock, gravel, rock), salvage all available topsoil [Section 8.2].	• Mixing of topsoil/root zone material and subsoil.

TABLE 7.4.2-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging (cont'd)	See above	Footprint	• Salvage topsoil/root zone material using specialized equipment capable of accurately separating variable depths of topsoil from subsoil (*e.g.,* frozen topsoil cutter, topsoil mulcher or equivalent, if available) [Section 8.2]. See additional measures in Section 8.2 of the Facilities EPP. • Overstrip shallow topsoils to the depth as indicated on the Environmental Facility Drawings [Section 8.2]. • Keep grade subsoil windrow separate from topsoil/root zone material windrow/berm. Maintain a minimum separation distance of 1 m between topsoil/root zone and grade subsoil windrows (see Drawing [Pump Station Construction – Topsoil/Root Zone Material Salvage] provided in Appendix R) [Section 8.2]. • Locate topsoil/root zone material windrows/berms along the boundaries of the facility footprint outside of the development zone area so they do not alter natural drainage patterns during periods of short and long-term storage and, if feasible, locate them on the upslope side of the site to avoid contamination from accidental spills [Section 8.2]. <u>Access Roads</u> • Do not salvage topsoil/root zone material from areas of the access road where construction activities will not result in extensive mixing of surface and subsoils or excessive damage to the upper soils, as determined by the Inspector [Section 9.0]. • Salvage all topsoil or the upper 15 cm of root zone material, where present, for use during clean-up and closure of new and upgraded access roads as directed by the Inspector [Section 9.0]. • Salvage topsoil/root zone material at new permanent and temporary access roads where grading, bar ditches, fill or other materials are necessary [Section 9.0]. <u>Power Lines</u> • Do not salvage topsoil/root zone material from areas of the power line right-of-way where construction activities will not result in extensive mixing of surface and subsoils or excessive damage to the upper soils, as determined by the Lead Activity Inspector and the Inspector [Section 11.1]. • Salvage all topsoil or the upper 15-20 cm of root zone material, where present and as required, for use during clean-up as directed by the Lead Activity Inspector and the Inspector [Section 11.1]. • Ensure enough workspace is available (approximately 0.5 m) to allow for the storage of augured subsoil material onto subsoil to reduce the risk of subsoil material sloughing into the hole on cultivated and poorly-sodded tame pasture and hay lands during nonfrozen soil conditions [Section 11.2]. • Ensure enough workspace is available (approximately 0.5 m) to allow for the storage of augured subsoil material onto unsalvaged topsoil/root zone material to reduce the risk of subsoil material sloughing into the hole on well-sodded tame pasture and hay lands, native grasslands and forested areas during nonfrozen soil conditions [Section 11.2].	• See above.

TABLE 7.4.2-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging (cont'd)	See above	Footprint	• During frozen soil conditions, ensure enough workspace is available (approximately 0.5 m) to allow for the storage of augured subsoil on a 10 cm buffer of snow, if available, or onto unsalvaged topsoil/root zone material to reduce the risk of subsoil material sloughing into the hole [Section 11.2]. • Feather-out excess subsoil material across the area where topsoil/root zone material has been salvaged [Section 11.2]. • Salvage topsoil/root zone material from areas where anchor pits will be excavated and store the topsoil/root zone material separately from material removed to excavate the pit, if applicable [Section 11.3]. • Place soil material removed to accommodate plate anchors utilized to secure the conductor during stringing activities adjacent to the site for use during backfilling [Section 11.3].	• See above.
1.2 Decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land	All	LSA	• See recommended mitigation measures from Table 7.2.2-2 which are also provided in Section 8.3 of the Facilities EPP.	• No residual effect identified.
1.3 Decreased soil productivity from soil diseases (*i.e.*, clubroot disease and potato cyst nematode)	Gainford Hinton Rearguard Darfield Black Pines Pump station Access road Power line Kingsvale Power line	LSA	• Ensure all construction equipment and vehicles, as well as personnel footwear, arrive on the construction site in a clean condition to reduce the risk of introducing or spreading clubroot disease or other crop disease(s) prior to topsoil/root zone material salvage activities. Refer to the Agriculture Management Plan (see Appendix C) for specific measures [Section 7.0]. • Apply tackifier (see Soil Erosion and Sediment Control Contingency Plan in Appendix B) to topsoil windrows in areas of known disease concern when there is potential for topsoil transfer during windy conditions, or if topsoil windrows are to be maintained over the winter, to prevent the possible spread of clubroot or other disease [Section 8.2].	• Clubroot disease introduction and spread. Potato cyst nematode introduction and spread.
2. Soil Indicator – Soil Degradation				
2.1 Degradation of soil structure due to compaction and rutting	Gainford Hinton Rearguard Darfield Black Pines Pump station Access road Power line Kingsvale Power line	Footprint	• Adhere to the measures outlined in the Wet/Thawed Soils Contingency Plan (Appendix B) during wet/thawed soil conditions [Section 7.0]. • Postpone construction, suspend equipment travel or utilize construction alternatives in the event of wet or thawed soils in order to reduce terrain disturbance and soil structure damage [Section 7.0]. • Ensure that there is sufficient frost or low enough soil moisture to allow construction without causing excessive rutting or soil compaction outside of the development zone [Section 8.2]. • Rip compacted subsoils with a multi-shank ripper or breaking disc to a depth of 30 cm or the depth of compaction, whichever is deeper. If soils are moist, postpone ripping of subsoils until soils dry to ensure that the soils fracture when ripped [Section 8.4]. • Cultivate or rip cultivated fields and hay, tame pasture, bush or woodlands on areas utilized during construction found outside of the fenced development zone, where poor sod development exists to a depth adequate to alleviate surface compaction and in a manner acceptable to the landowner. Do not cultivate into the subsoil [Section 8.4].	• Degradation of soil structure and impairment of rooting zone due to compaction and rutting.

TABLE 7.4.2-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.2 Loss of topsoil/root zone material through wind and water erosion	Gainford Hinton Rearguard Darfield Black Pines Pump station Access road Power line Kingsvale Power line	Footprint	Facilities • Ensure the potential for soil erosion by water is reduced during construction activities by avoiding ponding of water or the unintentional channelization of surface water flow [Section 7.0]. • Provide surface drainage of adequate capacity across the facility site and other Project-related facilities [Section 7.0]. • Inspect all water conveyance installations (*e.g.,* ditches and culverts) and ensure they are functioning appropriately. Take appropriate action prior to and during the spring freshet to clear culverts blocked by ice or debris [Section 7.0]. • Install erosion and sediment control structures and materials (*e.g.,* subsoil berm or sediment fencing) and implement, as warranted, erosion control measures outlined in the Soil Erosion and Sediment Control Contingency Plan (see Appendix B) to ensure that sediments in surface water draining from the facility site do not adversely affect the surrounding terrain or watercourses/wetlands/lakes. In particular, control erosion on grade cuts adjacent to the development zone at facility sites [Section 7.0]. • Revegetate the topsoil/root zone material windrows and areas of vegetation disturbed during construction to stabilize topsoil/root zone material and reduce weed growth [Section 8.2]. • Monitor topsoil/root zone material windrows during the growing season for wind and water erosion, and weed growth until the soils are replaced or stored in berms. Implement remedial measures to control erosion and weed growth, when warranted (see Soil Erosion and Sediment Control Contingency Plan in Appendix B and the Weed and Vegetation Management Plan in Appendix C) [Section 8.2]. • Revegetate as soon as practical following final clean-up to establish a long-term cover and reduce or avoid soil erosion. Seed immediately following topsoil/root zone material replacement [Section 8.4.3]. • Establish long-term topsoil/root zone material storage berms at locations away from regular facility operational activity and areas with potential for overland water flow and storage berm erosion [Section 8.4.3]. • Further mitigation measures for erosion control can be found in Sections 7.0, 8.2 and 8.4 of the Facilities EPP. Access Roads • Store all salvaged topsoil and root zone material from the new permanent or temporary access road bed area in windrows along one or both edges of the access road in a manner that does not alter natural drainage patterns [Section 9.0]. • Implement appropriate erosion and sediment control measures on topsoil/root zone material windrows (see Weed and Vegetation Management Plan in Appendix C) [Section 9.0]. • Seed the topsoil/root zone material immediately with a cereal grass cover crop species (see Section 8.0), unless otherwise directed by the Lead Activity Inspector and the Inspector, to reduce the risk of erosion [Section 9.0]. • Ensure adequate drainage by maintaining the proper grade and installing culverts to allow for cross drainage. Outslope the crown of the road so that it is a minimum of 15 cm higher than the shoulders to allow the road surface to drain and dry [Section 9.0].	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.

TABLE 7.4.2-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.2 Loss of topsoil/root zone material through wind and water erosion (cont'd)	See above	Footprint	• Top the road with clean gravel, where warranted. Consider using underlay felt liners, geotextiles, filter mats or matting if the soil conditions and drainage are poor and there is potential for rutting and erosion [Section 9.0] • Install/implement drainage and erosion control measures (*e.g.,* check dams, sediment traps, culverts), as warranted, during the development of new access roads and upgrading of existing roads/trails [Section 9.0]. • Seed disturbed side slopes and bar ditches (if present) on new and upgraded roads with an approved seed mix as provided in the Reclamation Management Plan (see Appendix C) [Section 9.0]. Power Lines • Store all salvaged topsoil/root zone material in windrows along one or both edges of the power line right-of-way in a manner that does not alter natural drainage patterns [Section 11.1]. • Seed the topsoil/root zone material immediately with a cereal grass cover crop species (see Section 8.0), unless otherwise directed by the Lead Activity Inspector and the Inspector, to reduce the risk of erosion or creation of weed habitat [Section 11.1].	• See above.
2.3 Degradation of soil structure due to pulverization of soil and sod	Gainford Hinton Rearguard Darfield Black Pines Pump station Access road Power line Kingsvale Power line	Footprint	• Assess the wind erosion hazard, competency of the sod, and potential for soil pulverization due to droughty soils. Notify the contractor if measures applicable to droughty, wind erodible soils, or where the biological soil crust has been disturbed, will be required to avoid or reduce the effect of soil pulverization and wind erosion [Section 8.2]. • Trans Mountain will consult with and inform landowners with the potential to be affected by dust emissions from construction activities prior to commencement of these activities in proximity to the respective landowners [Section 8.2]. • Salvage topsoil/root zone material in areas of equipment and vehicle travel where it is determined that soils may be prone to pulverization [Section 8.2]. • Limit cultivation in areas of fine textured soils to prevent pulverization of the soil [Section 8.4.3].	• Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.
2.4 Erosion of soil as a result of release of hydrostatic test water on land	All	LSA	• Monitor discharge locations to ensure that no erosion, flooding or icing occurs. If conditions become saturated to the extent that adequate natural filtration is no longer occurring, suspend dewatering and move the discharge to another approved location (confirm that appropriate approvals and, if warranted, soil testing have been completed) or construct a holding pond for the water and release the water when natural filtration is again feasible [Section 8.3]. • See recommended mitigation measures from Table 7.2.2-2 which are also provided in Section 8.3 of the Facilities EPP.	• No residual effect identified.
3. Soil Indicator – Soil Contamination				
3.1 Disturbance of previously contaminated soil	All	Footprint	• Implement the Contamination Discovery Contingency Plan (Appendix B) and applicable measures for the Waste Management Standard (see Appendix C) in the event contaminated soils are encountered during construction.	• No residual effect identified.
3.2 Contamination of soil as a result of hydrostatic test water on land	All	LSA	• See recommended mitigation measures from Table 7.2.2-2 which are also provided in Section 8.3 of the Facilities EPP.	• No residual effect identified.

TABLE 7.4.2-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.3 Soil contamination due to spot spills during construction	All	Footprint	• Maintain all appropriate spill response equipment/supplies at all work sites. Assess the risk of resource-specific spills to determine the appropriate type and quantity of spill response equipment and materials to be stored on-site and a suitable location for storage [Section 7.0]. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are released on the ground or into any watercourse/wetland/lake. In the event of a spill, implement the Spill Contingency Plan (see Appendix B) [Section 7.0]. • See additional spill prevention and clean up measures in Section 7.0 of the Facilities EPP.	• No residual effect identified.

Notes: 1 LSA = Soil LSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.4.2.3 Potential Residual Effects

The potential residual environmental effects on soil and soil productivity indicators associated with Project activities at pump station facilities (Table 7.4.2-1) are:

- mixing of topsoil/root zone material and subsoil;
- clubroot disease and potato cyst nematode introduction and spread;
- degradation of soil structure and impairment of rooting zone due to compaction and rutting;
- surface erosion of topsoil/root zone material can be expected until a vegetative cover is established; and
- pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.

Some of the potential effects on element indicators associated with Project activities at pump station facilities are predicted to be eliminated through the implementation of mitigation measures (Table 7.4.2-1). The potential effects determined not to have a residual effect are:

- decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land;
- erosion of soil as a result of release of hydrostatic test water on land;
- disturbance of previously contaminated soil;
- contamination of soil as a result of hydrostatic test water on land; and
- soil contamination due to spot spills during construction.

7.4.2.4 Significance Evaluation of Potential Residual Effects

Table 7.4.2-2 provides a summary of the significance evaluation of the potential residual environmental effects on soil and soil productivity indicators resulting from Project activities at pump station facilities.

TABLE 7.4.2-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON SOIL AND SOIL PRODUCTIVITY

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Soil Indicator – Soil Productivity									
1(a)	Mixing of topsoil/root zone material and subsoil.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Low	High	High	Not significant
1(b)	Clubroot disease and potato cyst nematode introduction and spread.	Negative	LSA	Short-term	Accidental	Long-term	High	Low	Moderate	Not significant
2.	Soil Indicator – Soil Degradation

2(b)	Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.	Negative	Footprint	Short-term	Isolated	Medium-term	Low	High	High	Not significant
2(c)	Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	Low to high	High	Not significant
2(d)	Combined effects on the soil degradation indicator (2[a] to 2[c]).	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant

Notes: 1 LSA = Soil LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the soil productivity indicator and soil degradation indicator was determined to be generally the same for the construction and operations of pump station facilities as for pipeline construction and operations (Table 7.4.2-2, points 1[a] and 1[b], 2[a] to 2[d]). The exception is the reversibility of mixing of topsoil/root zone material and subsoil (point 1[a]), which is considered medium-term for power lines, or areas replaced around the proposed development zone, but long-term where topsoil is stored in berms (*i.e.,* access roads). Table 7.2.2-3 and the accompanying discussion in Section 7.2.2.6 provides an evaluation of potential residual effects of Project activities at pump station facilities and their significance on the applicable soil and soil productivity indicator.

7.4.2.5 Summary

As identified in Table 7.4.2-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on soil and soil productivity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with Project activities at pump station facilities on soil and soil productivity will be not significant.

7.4.3 Water Quality and Quantity

Sections 7.2.3.1 and 7.2.3.2 provides the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of the Project activities at pump station facilities on water quality and quantity.

7.4.3.1 Water Quality and Quantity Context

No construction activities at pump stations are anticipated to occur within 30 m of any watercourse and the proposed operations access road to Black Pines Pump Station does not cross any watercourses. However, the proposed 2.2 km power line extending to Black Pines Pump Station crosses the North Thompson River and Otter and Voght creeks, and the proposed 23.5 km power line extending to Kingsvale Pump Station crosses Kanevale, Kimble, Howarth and Nisson creeks. Several NCDs and NVCs are also crossed.

Alteration of natural surface drainage patterns may occur during construction and operations of pump stations, particularly where considerable grading may be required (*e.g.,* Black Pines, Kingsvale, Kamloops), and along power lines and the proposed operations access road to Black Pines Pump Station.

Section 6.1 provides additional setting information related to water quality and quantity at the pump stations.

7.4.3.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the Project activities at pump station facilities on the water quality and quantity indicators listed in Table 7.4.3-1 were based on the results of the literature review, desktop analysis, field work, TEK, engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.4.3-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.3.4.

TABLE 7.4.3-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON WATER QUALITY AND QUANTITY

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Water Quality and Quantity Indicator – Surface Water Quality				
1.1 Contamination of surface water due to accidental release of hazardous materials during power line construction	Black Pines Power line Kingsvale Power line	LSA	• Isolate work areas in the vicinity of watercourses/wetlands/lakes to ensure water does not experience an increase in alkalinity beyond ambient conditions during construction [Section 11.2]. • Ensure that any concrete, cement, mortars or other lime-containing construction materials are not deposited, directly or indirectly, into or near any watercourse/wetland/lake [Section 11.2]. • Provide containment facilities for the wash-down water from cement delivery trucks, concrete pumping equipment and other tools and equipment [Section 11.2]. • Frequently monitor pH in watercourses immediately downstream of the isolated work site until completion of the cement or concrete residue work if located within 30 m of a watercourse/wetland/lake [Section 11.2]. • Prevent water that contacts uncured or partly cured concrete during activities such as exposed aggregate wash-off, wet curing or equipment washing from directly or indirectly entering a watercourse, waterbody or wetland [Section 11.2].	• No residual effect identified.

TABLE 7.4.3-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Contamination of surface water due to accidental release of hazardous materials during power line construction (cont'd)	See above	LSA	• Isolate and hold any water that contacts uncured or partly cured concrete until the pH is between 6.5 and 8.0, and the turbidity is less than 25 NTU measured to an accuracy of +/- 2 NTU [Section 11.2]. • See additional mitigation measures in Section 11.2 of the Facilities EPP.	• See above.
1.2 Suspended sediment in water column	Black Pines Power line Kingsvale Power line	LSA	• Install erosion and sediment control structures and materials (*e.g.,* subsoil berm or sediment fencing) [Section 7.0] and implement, as warranted, erosion control measures outlined in the Soil Erosion and Sediment Control Contingency Plan [Appendix B]. • Install sediment fences near the base of cut slopes following grading (see Sediment Fence Drawing provided in Appendix R of the Pipeline EPP). Inspect the temporary sediment control structures on a daily basis and repair, if warranted, before the end of each working day [Section 8.2]. • Dewater the augured hole if warranted, prior to the installation of the pole. Pump water onto stable and well-vegetated areas, tarpaulins or sheeting in a manner that does not cause erosion or any unfiltered or silted water to directly re-enter a watercourse/wetland/lake [Section 11.0]. • Ensure that dewatering points are not located within 50 m of a watercourse/wetland/lake. Dewatering locations must be approved by the Lead Activity Inspector and the Inspector [Section 11.0]. • Revegetate as soon as feasible to reduce or avoid soil erosion and establish long-term cover [Section 8.4]. • Reclaim all disturbances within one growing season. If feasible, seed and plant seedlings during early spring to take advantage of the spring precipitation [Section 8.4]. • Adhere to additional guidance provided in the Reclamation Management Plan [Appendix C]. • See also potential effects 1.2 of Table 7.2.3-2 and 1.2 of Table 7.3.3-2 for additional mitigation measures.	• Reduction in surface water quality due to suspended sediment during construction and operations of the Black Pines and Kingsvale power lines.
1.3 Reduction of surface water quality due to small spill during construction	Black Pines Power Line Kingsvale Power Line	LSA	• Maintain the identified separation distances between the following areas and a watercourse/wetland/lake when constructing the facility site, unless otherwise approved: - fuel or hazardous material storage site - 300 m; - burning site - 100 m; and - oil change area - 100 m [Section 7.0]. • See Section 7.0 of the Facilities EPP for additional measures for hazardous materials storage, servicing vehicles and spill equipment needs. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are dumped on the ground or into watercourses/wetlands/lakes. In the event of a spill, implement the Spill Contingency Plan [Appendix B] [Section 7.0].	• Contamination of surface water due to a small spill during construction.

TABLE 7.4.3-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.3 Reduction of surface water quality due to small spill during construction (cont'd)	See above	See above	• Conduct refuelling a minimum of 100 m from any watercourse/wetland/lake unless otherwise approved by the appropriate regulatory authority [Section 7.0]. See additional measures for refuelling near watercourses/wetlands/lakes in Section 7.0 of the Facilities EPP.	• See above.
2. Water Quality and Quantity Indicator – Surface Water Quantity				
2.1 Localized alteration of natural surface drainage patterns during construction and operations	Gainford Hinton Rearguard Darfield Black Pines Pump station Power line Access road Kamloops Kingsvale Pump station Power line	LSA	• Cut and fill the development zone, if required, to level the surface to be developed. Grade the surface to facilitate water drainage into water conveyance features (*e.g.*, ditches and culverts) [Section 8.2]. • Ensure the potential for soil erosion by water is reduced during construction activities by avoiding ponding of water or the unintentional channelization of surface water flow [Section 7.0]. • Establish long-term topsoil/root zone material storage berms at locations away from areas with potential for overland water flow [Section 8.4]. • Maintain or, when the area is stabilized, remove drainage and erosion control devices and materials, at all sites that are no longer in use [Section 7.0]. • Store all salvaged topsoil and root zone material from the new permanent access road and power line corridors in windrows along one or both edges of the access road and power line corridors in a manner that does not alter natural drainage patterns [Sections 9.0 and 11.1]. • Backfill to the surface and mound to allow for drainage away from the tower structure and settlement of soils. Mounding will not exceed 30 cm above grade, where feasible [Section 11.2]. • Feather-out excess subsoil material across the area where topsoil/root zone material has been salvaged. Avoid mixing topsoil/root zone material and feathered subsoil material. Blend feathered material into the natural grade of the area so as to not change local surface drainage patterns [Section 11.2]. • Recontour areas disturbed during facility construction outside of the development zone to pre-construction contours (where feasible) and drainage channels [Section 8.4]. • Provide surface drainage of adequate capacity across the facility site and other Project-related facilities [Section 7.0].	• Localized alteration of natural surface drainage patterns at pump stations, operations access road and along power lines.
3. Water Quality and Quantity Indicator – Groundwater Quality				
3.1 Reduction of groundwater quality as a result of a small spill during construction	Black Pines Power line Kingsvale Power line	LSA	• Implement mitigation measures from the Facility EPP to reduce the risk possibility of a spill during construction.	• Contamination of groundwater as a result of a small spill during construction.

Notes: 1 LSA = Water Quality and Quantity LSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.4.3.3 Potential Residual Effects

The potential residual environmental effects on water quality and quantity indicators associated with Project activities at pump station facilities (Table 7.4.3-1) are:

- reduction in surface water quality due to suspended sediment during construction and operations of the Black Pines and Kingsvale power lines;
- contamination of surface water from a small spill during construction;
- localized alteration of natural surface drainage patterns at pump stations, operations access road and along power lines; and
- contamination of groundwater as a result of a small spill during construction.

Potential effects on the surface water quality indicator as a result of accidental release of hazardous materials at pump station facilities are predicted to be eliminated through the implementation of mitigation measures and no residual effect is anticipated (Table 7.4.3-1).

7.4.3.4 Significance Evaluation of Potential Residual Effects

Table 7.4.3-2 summarizes the significance evaluation of the potential residual environmental effects on water quality and quantity indicators resulting from Project activities at pump station facilities.

TABLE 7.4.3-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON WATER QUALITY AND QUANTITY

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Water Quality and Quantity Indicator – Surface Water Quality									
1(a)	Reduction in surface water quality due to suspended sediment during construction and operations of the Black Pines and Kingsvale power lines.	Negative	LSA	Immediate to short-term	Isolated to occasional	Immediate to short-term	Low	High	High	Not significant
1(b)	Contamination of surface water due to a small spill during construction.	Negative	LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
2.	Water Quality and Quantity Indicator – Surface Water Quantity									
2(a)	Localized alteration of natural surface drainage patterns at pump stations, operations access road and along power lines.	Negative	LSA	Short-term	Isolated to occasional	Short to long-term	Low	High	High	Not significant
3.	Water Quality and Quantity Indicator – Groundwater Quality									
3(a)	Contamination of groundwater as a result of a small spill during construction.	Negative	LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant

Notes: 1 LSA = Water Quality and Quantity LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of contamination of surface water and groundwater due to a small spill during construction (Table 7.4.3-2, points 1[b] and 3[a]) was determined to be the same for the construction and operations of pump station facilities as for pipeline construction and operations. Table 7.2.3-3 and the accompanying discussion in Section 7.2.3.6 provides an evaluation of these potential residual effects of pump station facilities and their significance on the surface water quality and groundwater quality indicators. The rationale used to evaluate the significance of each of the remaining residual environmental effects on the water quality and quantity indicators is provided below.

Water Quality and Quantity Indicator – Surface Water Quality

The following provides the evaluation of significance of potential residual effects on the surface water quality indicator.

Suspended Sediment Release

Some erosion may cause sediment input and subsequent reduction in surface water quality during construction and operations of the Black Pines and Kingsvale power lines. The impact balance of this potential residual effect is considered negative since the erosion could decrease surface water quality of nearby waterbodies.

Power line towers will be installed outside of the riparian area of any watercourses, reducing the potential for any eroded sediments to enter the water column. In addition to disturbance around towers, soil disturbance will be required where anchor pits will be excavated for conductor stringing and possibly at other areas of the power line rights-of-way where soil disturbance necessitates construction (*e.g.,* vehicle and equipment use). However, given the limited surface disturbance required for power line construction, and through implementation of mitigation measures in Table 7.4.3-1 and the Facilities EPP (Volume 6C), any reduction in surface water quality due to suspended sediment during construction and operations of the Black Pines and Kingsvale power lines is anticipated to be of low magnitude. This residual effect is reversible in the immediate to short-term (Table 7.4.3-2, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – any sedimentation caused by erosion will be carried downstream until it disperses and/or naturally settles out within the predicted ZOI.
- Duration: immediate to short-term – the event causing the erosion and sedimentation of surface water is construction or maintenance activities (*e.g.,* pole replacements), the latter of which is completed during any one year during the operations phase.
- Frequency: isolated to occasional – the event resulting in sedimentation caused by erosion is confined to a specific phase of the assessment period (*i.e.,* power line construction) or will occur intermittently and sporadically over the assessment period (*i.e.,* power line maintenance).
- Reversibility: immediate to short-term – an increase in suspended sediments has the potential to occur until effective erosion and sediment control measures are in place following power line construction.
- Magnitude: low – any increase in suspended sediments would occur over a short-term timeframe and is anticipated to be within CCME guidelines given the implementation of mitigation measures to reduce sedimentation.
- Probability: high – it is reasonable to anticipate that a minor amount of sediment may enter a waterbody during construction and maintenance activities along the Black Pines and Kingsvale power lines.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Water Quality and Quantity Indicator – Surface Water Quantity

The following provides the evaluation of significance of potential residual effects on the surface water quantity indicator.

Alteration of Natural Drainage Patterns

Drainage patterns will be altered at Black Pines Pump Station and associated operations access road, as well as at existing pump stations where grading is required and along new power lines. The impact balance of this potential residual effect is considered negative since it could alter or disrupt natural above ground hydrologic conditions. However, reducing impacts to natural drainage patterns is an important aspect of site selection, facility design and construction, and routing. Given that pump stations and the operations access road have been sited to reduce alteration of natural drainage patterns (*i.e.,* by avoiding to the extent feasible areas requiring extensive grading and surface alteration), and through implementation of mitigation measures in Table 7.4.3-1 and the Facilities EPP (Volume 6C) to ensure the maintenance of surrounding surface water drainage patterns (*e.g.,* culverts to ensure cross drainage under access roads), disruption of surface flow patterns during construction and operations is likely to be minor. Nevertheless, the residual effect is reversible in the long-term since natural drainage patterns at pump stations and operations access roads will be restored during decommissioning and abandonment of the Project (*i.e.,* greater than 10 years).

Due to the limited surface disturbance required for power line construction (*i.e.,* typically at pole installation sites and where disturbance is required for conductor stringing), and given mitigation measures in Table 7.4.3-1 and the Facilities EPP (Volume 6C), power line construction is expected to have a minimal effect on surface flow patterns. The residual effect is reversible in the short to long-term since natural drainage patterns at pump stations and the access road may not be fully restored until decommissioning and abandonment.

In the event that construction or maintenance activities result in changes in surface water regimes, corrective action, in consultation with the appropriate authorities, will be conducted to resolve the issue. The residual effect is considered to be of low magnitude (Table 7.4.3-2, point 2[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – although alteration of natural drainage patterns is generally confined to the disturbed portion of pump stations, operations access road and power lines, potential changes in hydrology may extend beyond the facility, road and power line easements.
- Duration: short-term – the event causing alteration of natural drainage is construction of the operations access road as well as construction or maintenance activities (*e.g.,* site maintenance, pole replacements) at Black Pines Pump Station, existing pump stations where activities are planned and along new power lines.
- Frequency: isolated to occasional – the event causing alteration of natural drainage is confined to a specific phase of the assessment period (*i.e.,* construction) or will occur intermittently and sporadically over the assessment period (*i.e.,* maintenance of the pump stations, operations access road and power lines).
- Reversibility: short to long-term – short to medium-term for power lines where it may take more than one year to restore natural drainage patterns and long-term (*i.e.,* greater than 10 years) for pump stations and the access road where natural drainage patterns will not be fully restored until decommissioning and abandonment.
- Magnitude: low – surface water passage will be unimpeded at the Black Pines Pump Station and associated operations access road, as well as along power lines, and any alteration of surface water drainage at existing pump stations where construction activities are planned is expected to be minor.
- Probability: high – construction and operations of the pump station facilities, operations access road and power lines is likely to affect natural drainage patterns in localized areas.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

7.4.3.5 Summary

As identified in Table 7.4.3-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on water quality and quantity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with Project activities at pump station facilities on water quality and quantity will be not significant.

7.4.4 Air Emissions

Sections 7.2.4.1 and 7.2.4.2 provide the assessment indicator, measurement endpoints and spatial boundaries for the assessment of potential effects of Project activities at pump station facilities on air emissions. Estimated air emissions from pump station construction and operation are described in Section 7.2.4.3 and summarized in Table 7.2.4-2.

7.4.4.1 Potential Effects and Mitigation Measures

Effects Considerations

No advanced dispersion modelling was performed to estimate ambient VOC concentrations associated with fugitive VOC emissions during pump station operation. Instead, a screening level assessment was performed using the AERSCREEN model for the Edson, Gainford and Wolf pump stations representing large, medium, and small pump stations in terms of fugitive emission rates. The Edson Pump Station has two existing 2000 HP pumps for the existing TMPL system and three existing 75 HP booster pumps, and will be expanded by three 5000 HP pumps for TMEP. The Gainford Pump Station has three existing 2000 HP pumps for the existing TMPL system, and the TMEP will introduce three 5000 HP pumps. At the Wolf Pump Station, two 5000 HP pumps will be added for TMEP. The AERSCREEN results indicate that maximum predicted 1-hour concentrations of BTEX and mercaptans would be <1% of their respective ambient air quality objectives except for benzene, which is predicted to be <3% of the ambient objective. As a result of this very low level of effect, a residual potential effects assessment was not performed for fugitive emissions from pump station operation.

Air emissions also occur during site-specific maintenance and inspection activities (*e.g.,* from vehicles and fuel usage for space heating). These emissions are expected to be very low compared to other existing emissions in the Air Quality RSA for example from non-Project related vehicles movements. Furthermore, it is not clear if the Project will lead to additional maintenance and inspection activities. Therefore, a residual potential effects assessment was not performed for air emissions from the maintenance and inspection of pump stations.

Identified Potential Effects

Potential effects on the air emissions indicator that are associated with the Project activities at pump stations and listed in Table 7.4.4-1 were based on the results of the literature review, desktop analysis, consultation with stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

The summary of the mitigation measures provided in Table 7.4.4-1 was principally developed in accordance with Trans Mountain standards and accepted facility construction methods for construction-related activities.

TABLE 7.4.4-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON AIR EMISSIONS

Potential Effect	Pump Stations	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds				
1.1 Project contribution to emissions	All	RSA	• Trans Mountain will consult with and inform landowners of the potential to be affected by emissions from construction activities prior to commencement of these activities in proximity to the respective landowners [Section 7.0]. • Restrict the duration that vehicles and equipment are allowed to sit and idle to less than one hour unless air temperatures are less than 0°C [Section 7.0]. • Ensure equipment is well-maintained during construction to minimize air emissions [Section 7.0].	• Increase in air emissions during construction of pump stations.

TABLE 7.4.4-1 Cont'd

Potential Effect	Pump Stations	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Project contribution to emissions (cont'd)	See above	See above	• Use multi-passenger vehicles for the transportation of crews to and from the job sites, where feasible [Section 7.0].	• See above.
1.2 Dust during construction	All	RSA	• Trans Mountain will consult with and inform landowners with the potential to be affected by dust emissions from construction activities prior to commencement of these activities in proximity to the respective landowners [Section 8.2].	• Increase in fugitive dust during construction of pump stations.

Notes: 1 RSA = Air Quality RSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.4.4.2 Potential Residual Effects

The potential residual environmental effects on the air emissions indicator associated with the construction and operations of pump stations (Table 7.4.4-1) are:

- an increase in air emissions during construction of pump stations; and
- an increase in fugitive dust during construction of pump stations.

7.4.4.3 Significance Evaluation of Potential Residual Effects

A qualitative assessment of air emissions from pump station construction activities was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects since there is a lack of regulatory thresholds, standards, or guidelines for indicators associated with construction emissions. Consequently, the evaluation of significance of each of the potential residual effects relies on the professional judgment of the assessment team.

Table 7.4.4-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of pump stations on the air emissions indicator.

TABLE 7.4.4-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON AIR EMISSIONS

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds									
1(a) Increase in air emissions during construction of pump stations.	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant
1(b) Increase in fugitive dust during construction of pump stations.	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant
1(c) Combined effects on the primary emissions of CACs and VOCs indicator (1[a] to 1[b]).	Negative	RSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not significant

Notes: 1 RSA = Air Quality RSA.
2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the primary emissions of CACs and VOCs indicator (Table 7.4.4-2, points 1[a] to 1[c]) was determined to be the same for the construction and operations of pump station facilities as for pipeline construction and operations. Table 7.2.4-4, points 1[a], 1[c], and 1[d], and the accompanying discussion in Section 7.2.4.6 provide an evaluation of potential residual effects of Project activities at pump station facilities and their significance on the primary emissions of CACs and VOCs indicator.

7.4.4.4 Summary

As identified in Table 7.4.4-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the air emissions indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of Project activities at pump station facilities on air emissions will be not significant.

7.4.5 Greenhouse Gas Emissions

As discussed in Section 7.2.5.3, during the construction phase, land clearing for pump station facilities and associated power lines, site preparation, operation of vehicles and equipment, and other construction activities will result in GHG emissions. During operation of the pump stations, direct GHG emissions are caused by fuel combustion for space heating, and fugitive emissions from valves, connectors, and pumps. Electricity consumption by the pump assemblies will result in indirect GHG emissions. Pump station related GHG emissions are summarized in Table 7.2.5-3.

The assessment of effects on GHG emissions has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, Westridge Marine Terminal and pipeline reactivation), since GHG emissions associated with the construction and operation of each Project component are aggregated for the Project as a whole and then compared to provincial and federal GHG inventory totals.

The assessment of effects on GHG emissions for the Project as a whole is presented in Section 7.2.5. Table 7.2.5-8 and accompanying discussion in Section 7.2.5.3 provide an evaluation of potential residual effects of Project activities at pump station facilities on GHG indicators.

7.4.6 Acoustic Environment

Sections 7.2.6.1, 7.2.6.2 and 7.2.6.3 provide the assessment indicators, measurement endpoints, spatial boundaries and acoustic environment context for the assessment of potential effects of the Project activities at pump station facilities on the acoustic environment.

In addition to the endpoints presented previous in Section 7.2.6.1, Health Canada document entitled "*Guidance for Evaluating Human Health Impacts in EA: Noise*" suggests alternative methods that differ from the BC OGC *Noise Control Best Practices Guideline* and AER *Directive 038* documents as well as the upper limit threshold. This guidance alternative will provide a secondary set of limits for the operational condition of the pump station operations that provides a greater perspective for effects from changes in sound levels in urban or densely developed areas. A draft Health Canada guidance document (Health Canada 2011) suggests annoyance based criteria (% highly annoyed or %HA) which relates noise levels to subjective human responses in order to establish criteria. Details on this alternative approach are provided in the Terrestrial Noise and Vibration Technical Report of Volume 5C.

TABLE 7.4.6-1

ASSESSMENT INDICATOR AND MEASUREMENT ENDPOINTS FOR ACOUSTIC ENVIRONMENT

Acoustic Environment Indicator	Measurement Endpoint(s)	Rationale for Indicator Selection
Sound levels	• Energy equivalent (L_{eq}) sound level measured in A-weighted decibels • Percent highly annoyed (%HA)	The L_{eq} indicator is defined by the assessment methods cited in the NEB *Filing Manual* under the acoustic environment element in Table A-2. The %HA indicator is representative of densely populated areas.

7.4.6.1 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

The potential effects associated with the Project activities at pump station facilities on the acoustic environment indicators listed in Table 7.4.6-1 were based on the results of desktop analysis, modelling and engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.4.6-2 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.6.4.

TABLE 7.4.6-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON ACOUSTIC ENVIRONMENT

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Acoustic Environment Indicator – Sound Level				
1.1 Changes in sound levels during construction	Edmonton Gainford Wolf Niton Edson Hinton Jasper Rearguard Blue River Black Pool Darfield Black Pines Pump station Access road Power line Kamloops Kingsvale Pump station Power line Sumas	LSA	• Adhere to all federal (*i.e.,* Environment Canada, *Motor Vehicle Safety Act*, *Oil and Gas Occupational Safety and Health Regulations*, Health Canada) and provincial (*i.e.,* Alberta's Energy Resource Conservation Board through Directive 038: Noise Control, BC OGC, *Worker's Compensation Act*, *Occupational Health and Safety Regulations* [BC Reg 296/97 as amended] Section 7.2 [BC Reg. 382/2004, s.1]) guidelines and legislation for noise management [Section 7.0]. • Schedule construction activities to be conducted within 300 m of residences, cabins, occupied campgrounds or parks in accordance with applicable municipal noise bylaws or approval conditions [Section 7.0]. • Noise abatement and construction scheduling will be considered at noise-sensitive locations and during noise-sensitive periods, to limit disruption to sensitive receptors (*i.e.*, neighbouring landowners, wildlife migratory periods, nesting birds) [Section 7.0]. • Enforce vehicle speed limits and inform contractor truck drivers and equipment operators that engine retarder braking in urban areas is prohibited [Section 7.0]. • Maintain equipment in good working condition and in accordance with manufacturer guidelines [Section 7.0]. • Maintain noise suppression equipment on all construction machinery and vehicles in good order [Section 7.0]. • Enclose noisy equipment and use baffles, where and when feasible, to limit the transmission of noise beyond the construction site. • Use only the size and power of tools necessary limit noise from power tool operations [Section 7.0]. • Locate stationary equipment, such as compressors and generators located away from noise receptors, to the extent feasible, and follow applicable municipal, provincial and federal guidelines [Section 7.0].	• Increase in sound levels at pump station and associated facilities during construction period.

TABLE 7.4.6-2 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Changes in sound levels during construction (cont'd)	See above	LSA	• Implement mitigation measures where residences are located within 300 m of the construction right-of-way or facility site as outlined in the Noise Management Plan [Section 7.0]. • Implement mitigation measures where night-time activity (*e.g.,* horizontal directional drill) on the construction right-of-way or facility site is located within 500 m of residences as outlined in the Noise Management Plan [Section 7.0].	• See above.
1.1 Changes in sound levels during operations	Edmonton Gainford Wolf Niton Edson Hinton Rearguard Blue River Black Pool Black Pines Kamloops Kingsvale Sumas	LSA	• Review and analyze equipment specifications to ensure sound emissions from mechanical equipment are equal to or less than the sound emissions used in the Terrestrial Noise and Vibration Technical Report. • Limit helicopter inspections to weekdays only where practical. • Use of off-road vehicles for inspection should be limited to weekdays.	• Increase in continuous sound levels from operations of new pump stations.

Notes: 1 LSA = Acoustic Environment LSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.4.6.2 Residual Effects

The potential residual environmental effects on the acoustic environment indicators associated with Project activities at pump station facilities (Table 7.4.6-2) are:

- increases in sound levels at pump station and associated facilities during construction period; and
- increase in continuous sound levels from operations of new pump stations.

7.4.6.3 Significance of Residual Effects

Table 7.4.6-3 provides a summary of the significance evaluation of the potential residual environmental effects on the acoustic environment indicator resulting from Project activities at pump station facilities.

A quantitative assessment of the acoustic environment was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects for pump station facilities. The evaluation of significance of each of the potential residual effects for the acoustic environment relies primarily on the magnitude, duration and frequency of the potential change. The general definitions for these elements are provided in Table 7.1-2. However, magnitude of residual effects requires further definition for the acoustic environment evaluation and is indicator specific. Magnitude for sound level has been defined based on the degree of compliance with provincial and suggested Health Canada guidelines. Details on the guidelines and legislation used to establish the magnitude ratings are provided in the Terrestrial Noise and Vibration Technical Report.

The definitions of magnitude for the L_{eq} in dBA indicator for construction activities at pump station facilities are the same as the pipeline construction in Section 7.2.6.6.

The sound levels indicator definitions of magnitude for pump station operations are as follows.

- **Negligible:** Below BC OGC and AER ASL.

- **Low:** Below BC OGC/AER PSL limits and suggested Health Canada percent Highly Annoyed (%HA) guidance.
- **Medium:** Equal to or slightly lower than the BC OGC/AER PSL limit in rural or sub-urban areas; or Health Canada %HA guidance in urban areas.
- **High:** Greater than either the BC OGC/AER PSL limit or the Health Canada %HA guidance.

TABLE 7.4.6-3

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Acoustic Environment Indicator – Sound Levels

Increases in Sound Levels During Construction

The potential for the increase in sound levels for human receptors associated with Project construction is considered to have a negative impact balance. It is anticipated that the sound levels due to the construction of the pipeline will be greater than the sound levels generated by the construction at each pump station and associated power lines due to the reduced number of active pieces of construction equipment required. Although some incremental clearing is required at Gainford, Hinton, Rearguard and Darfield pump stations, only the Black Pines Pump Station will require clearing activity for a new site. All other sites will use already cleared space and earthworks or excavation is expected to be minimal. Therefore, sound emitted by pump station construction is evaluated at receptors based on the “Installation of Building Structures and Equipment” in Figure 7.2.6-1, with the exception of Black Pines where “Clearing” from Figure 7.2.6-1 is considered. Details on the residual effects from pipeline construction are described in detail in Section 7.2.6.6. All of the significance criteria rankings and supporting rationale, with the exception of magnitude, will be the same as Section 7.2.6.6.

The results for the construction of the pump stations indicates the magnitude of changes in sound levels that will be experienced by people living within 1.5 km of a station where new pumps are proposed. Noise controls that will be used during the construction phase, particularly the use of silencers on mobile equipment and developing a noise management plan are expected to control the amount of sound to within acceptable levels as established in the Terrestrial Noise and Vibration Technical Report of Volume 5C. Controlling the magnitude of sound levels also limits the spatial extent of the potential change.

The only variation in residual affects is the magnitude of potential effects. This varies depending on the distance between the construction activities and the surrounding receptors. Table 7.4.6-4 presents a summary of the relevant parameters and predicted magnitude.

TABLE 7.4.6-4

SUMMARY OF SOUND LEVEL MAGNITUDE FOR APPLICABLE PUMP STATION CONSTRUCTION

Pump Station Facility	Distance to Closest Receptor (m)	Predicted Sound Level (dBA)	Criteria		Magnitude
			BC OGC/AER Daytime PSL (dBA)	Health Canada Guidance (dBA)	
Edmonton, AB	No receptor within the Acoustic Environment LSA. Closest receptor is 1.9 km.	56	60	75	Low
Gainford, AB	140	79	65	75	High
Edson, AB	360	71	65	75	Medium
Hinton, AB	820	64	65	75	Low
Rearguard, BC	No receptor within the Acoustic Environment LSA. Closest receptor is 3.5 km.	<51	65	75	Negligible
Blackpool, BC	150	78	65	75	High
Black Pines, BC	100	84	65	75	High
Kamloops, BC	520	68	63	75	Medium
Kingsvale, BC	300	72	60	75	Medium
Sumas, BC	110	81	65	75	High

Other pump stations, though not numerically assessed, may have construction activities related to the Project. Construction sound levels are anticipated to fall within the ranges listed above. If a high magnitude is predicted, a detailed noise management plan for construction should be implemented. A summary of the rationale for all of the significance criteria is provided below (Table 7.4.6-3, point 1[a]).

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER *Directive 038* (ERCB 2007) and BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) are achieved within the Acoustic Environment LSA.
- Duration: short term – the event causing the increase in sound levels occur during the construction phase.
- Frequency: isolated – the events causing the increase in sound levels occur only during the construction phase in which the activity is planned.
- Reversibility: short-term – the increases in sound levels will occur during construction activities at pump stations which will last up to 2 years. All construction sound level changes are reversible as the sound will cease when construction is finished.
- Magnitude: negligible to high – increases in sound levels range primarily between negligible to medium. High magnitude ratings at Black Pines and Sumas pump stations can be controlled to within the range of medium magnitude effects with the implementation of a detailed noise management plan.
- Probability: high – based on the proximity of residences to the pump station facility, increased sound levels may affect receptors during construction.
- Confidence: moderate – based on the nature of data inputs.

Increase in Continuous Sound Levels from Operations of New Pump Stations

The potential for the increase in sound levels for human receptors associated with Project pump station operations is considered to have a negative impact balance. Noise from pump station facility operations where new pumps have been added for the Project will be continuous sound from pumping and support equipment located on these sites. Where new pump stations have been sited, these sounds will be new to the local area. For replacements or reactivation of existing pump stations, sounds would be similar to those already generated on these sites.

The spatial extent of the increase in sound levels during operations of the pump stations is limited to the Acoustic Environment LSA. The duration of the pump station sounds is long-term, throughout the operating life of the pump station. The increase in sound levels during operations will extend for the operating life of the pump station and, consequently, is of long-term reversibility. However, effect is reversible as the increase in sound levels cease as soon as the sound stops, which would be following Project decommissioning.

The only variation in residual affects at the pump stations is the magnitude of potential effects. This varies depending on the relative increase in sound emitting equipment, distance between the pump station and the surrounding receptors. As such, Table 7.4.6-5 presents a summary of the relevant parameters and resulting predicted magnitude.

TABLE 7.4.6-5

SUMMARY OF SOUND LEVEL MAGNITUDE FOR APPLICABLE PUMP STATION OPERATIONS

Pump Station Facility	Distance to Closest Receptor (m)	Predicted Sound Level (L_{eq} in dBA/%HA)	Criteria		Magnitude
			BC OGC/AER Nighttime PSL (dBA)	Health Canada Guidance (% HA)	
Edmonton, AB	No receptor within Acoustic Environment LSA. Compliance is demonstrated at Acoustic Environment LSA limit of 1.5 km.	36/1.2	40	6.5%	Low
Gainford, AB	140	45/3.2	45	6.5%	Medium
Wolf, AB	--	--/--	--	--	Negligible[1]
Edson, AB	360	42/2.6	45	6.5%	Low
Hinton, AB	820	40/2.2	45	6.5%	Negligible
Rearguard, BC	No receptor within Acoustic Environment LSA. Compliance is demonstrated at Acoustic Environment LSA limit of 1.5 km.	35/1.2	40	6.5%	Negligible
Blue River, BC	--	--/--	--	--	Negligible[1]
Blackpool, BC	150	43/2.8	45	6.5%	Low
Black Pines, BC	100	38/1.4	40	6.5%	Low
Kamloops, BC	520	39/1.8	43	6.5%	Low
Kingsvale, BC	300	37/1.3	40	6.5%	Low
Sumas, BC	110	47/3.9	55	6.5%	Low

Note: 1 No numeric assessment completed since at the time of the assessment, the pump unit changes consisted of replacement of equipment which have equivalent units.

A summary of the rationale for all of the significance criteria is provided below (Table 7.4.6-3, point 1[b]).

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER *Directive 038* (ERCB 2007) and BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) are achieved within the Acoustic Environment LSA.
- Duration: long-term – the event causing the increase in sound levels is the operation of the pump stations which occurs over the life of the operating pipeline.
- Frequency: continuous – the pump stations operate continuously over the life of the operating pipeline.
- Reversibility: long-term – the increase in sound levels during operations at pump stations will extend over the life of the operating pipeline. All sound level changes are reversible as the sound will cease when the pipeline is decommissioned.
- Magnitude: negligible to low – with the implementation of appropriate mitigation measures at the pumps stations, noise levels at receptors are expected to comply with AER, BC OGC and Health Canada limits.

- Probability: high – the new pumps are mechanical sources of sound and will increase sound levels for nearby receptors during operations.
- Confidence: moderate – the assessment is based on a combination of measured existing data, theoretical formulae and current Project design.

Combined Effects on Sound Levels

The evaluation of the combined effects of Project activities at pump station facilities on the acoustic environment considers collectively the assessment of the likely potential residual effects on the sound levels indicators. The residual effects for the sound levels indicator do not combine to result in new ratings for the various components since the occurrences of sound happen at different times during the Project. Therefore, the combined effects represents the worst-case or most negative effect for each evaluation criteria between the two residual effects (Table 7.4.6-3, point 1[c]). Effectively, this is the effect from pump station operations, since pump station construction is of short-term duration and reversibility. Pump station operations will occur continuously over the life of the operating pipeline. A summary of the rationale for all of the significance criteria of combined effects on sound levels is provided below.

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER *Directive 038* (ERCB 2007) and BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) are achieved within the Acoustic Environment LSA.
- Duration: long-term – the combined effect on sound levels reflects the operations of the pump stations which occur over the life of the operating pipeline.
- Frequency: continuous – the event causing combined effects on sound levels is the operation of pump stations which occur continuously over the life of the operating pipeline.
- Reversibility: long-term – the combined effect of sound levels reflect operations at pump stations which will extend over the life of the operating pipeline. All sound level changes are reversible since the sound will cease when the pump station is decommissioned.
- Magnitude: negligible to medium – with the implementation of appropriate mitigation measures at the pumps stations, noise levels at receptors are expected to comply with AER, BC OGC and Health Canada limits.
- Probability: high – the new pumps are mechanical sources of sound and will increase sound levels for nearby receptors during operation.
- Confidence: moderate – the assessment is based on a combination of measured existing data, theoretical formulae and current Project design.

7.4.6.4 Summary

As identified in Table 7.4.6-3, there are no situations arising from Project activities at pump station facilities where there is a high probability of occurrence of a permanent or long-term residual environmental effect on acoustic environment indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual effects associated with the Project activities at pump station facilities on the acoustic environment will be not significant.

7.4.7 Fish and Fish Habitat

The construction of power lines associated with construction of the Black Pines and Kingsvale pump stations may cause an interaction with fish and fish habitat indicators through a disturbance to riparian habitat and effects to indicator species.

Four indicator species (*i.e.,* bull trout/Dolly Varden, Chinook salmon, coho salmon and rainbow trout/steelhead) are known to occur in the Lower North Thompson, Lower Nicola and Similkameen river watersheds, in which the power lines associated with the Black Pines and Kingsvale pump stations are located.

The proposed power line associated with the Black Pines Pump Station crosses the North Thompson River, Otter Creek and Voght Creek, of which only the North Thompson River was determined to be fish-bearing (Section 5.4 of the Fisheries [British Columbia] Technical Report of Volume 5C). The proposed power line associated with the Kingsvale pump station crosses two fish-bearing watercourses, Kanevale Creek and Howarth Creek (Section 5.5 of the Fisheries [British Columbia] Technical Report of Volume 5C). In the event that power line towers associated with either pump station are constructed in riparian habitat, there may be an effect to riparian habitat overall and for the four indicator species present in the watershed.

The assessment of effects on fish and fish habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks and pipeline reactivation), since the components will have similar effect pathways (*i.e.,* riparian habitat, instream habitat and fish mortality and injury) on fish indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for fish indicators.

The assessment of effects on fish and fish habitat for the Project as a whole is presented in Section 7.2.7. Table 7.2.7-3 and accompanying discussion in Section 7.2.7.6 provide an evaluation of potential residual effects of pump station activities on fish indicators.

7.4.8 Wetland Loss or Alteration

Sections 7.2.8.1 and 7.2.8.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of the Project activities at pump station facilities on wetlands.

7.4.8.1 Ecological Context

Wetlands near or within the boundaries of the pump stations and along the proposed power lines were initially identified during helicopter overflights and through satellite imagery interpretation using key indicators such as terrain, surficial material (*i.e.,* mineral or organic), vegetation cover and the presence or absence of surficial hydrology. Through this method it was determined that 1 potential wetland is located within the Blackpool Pump Station boundary, however, Trans Mountain has confirmed that the proposed construction works at the Blackpool Pump Station will not affect this wetland, and nor the 23 potential wetlands which may be crossed by the proposed Kingsvale power line. Wetland classification and delineations will be confirmed during the 2014 supplemental wetland field surveys (see Section 9.0). Section 7.2.8.3 provides additional ecological context information.

7.4.8.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the Project activities at pump station facilities on wetland loss or alteration are listed in Table 7.4.8-1. These interactions are based on the results of the literature review, available research literature, desktop analysis, TEK, engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.4.8-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines, learnings from wetland post-construction environmental monitoring for previous projects and peer-reviewed publications on wetland function as described in Section 7.2.8.4.

TABLE 7.4.8-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON WETLAND LOSS OR ALTERATION

	Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.	Wetland Loss or Alteration – Wetland Function				
1.1	Potential loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.,* habitat, hydrology, biogeochemistry)	Blackpool Kingsvale Power line	LSA	<u>Habitat</u> • Ensure that all required approvals, licenses and permits are in place prior to commencing applicable construction activities [Section 6.0]. • Ensure TWS does not encroach within vegetated buffers at waterbodies or wetlands unless approved by the appropriate regulatory authority [Section 6.0]. • Ensure approvals are in place prior to works where the facility boundary encounters the boundaries of wetlands [Section 7.0]. • Protect vegetation mat from construction disturbance, to the extent feasible. Any TWS located within the boundary of a wetland must be approved by the Inspector [Section 7.0]. • Locate all additional work areas (such as graded areas or additional topsoil/root zone material storage areas) a minimum of 10 m from wetland boundaries except where adjacent upland is cultivated or hay land, or disturbed land, unless otherwise approved. Ensure landowner/land authority approvals are in place for all additional TWS prior to use [Section 7.0]. • Conduct ground level cutting, mowing and/or mulching of wetland vegetation instead of grubbing. The method of removal of wetland vegetation is subject to approval by the Inspector [Section 7.0]. • Prevent ground disturbance by using a protective layer such as frost packing, snow, ice or matting between wetland vegetation mat/seedbed and construction equipment [Section 7.0]. • Allow wetlands to recover naturally (*i.e.,* do not seed wetland areas) [Section 7.0]. • Restrict root grubbing in wet areas, where practical, to avoid creation of bog holes [Section 8.1]. • Align new access roads or extensions of existing roads to avoid wetlands and peatlands, to the extent feasible [Section 9.0]. • Conduct pre-clearing of timber and/or mowing of native pasture/hay where directed by the Inspector prior to the onset of the migratory bird nesting season (see Appendix L for listing of dates) [Section 8.1]. • Consider install bird deterrents (*e.g.,* avian reflectors, marker balls, swinging markers, flappers) on shield wires (where applicable) in the vicinity of select wetlands and riparian areas to deter birds away from the infrastructure [Section 11.3]. <u>Hydrology</u> • Install berms and/or cross ditches on approach slopes to wetlands, where warranted [Section 7.0]. • Ensure that dewatering points are not located within 50 m of a watercourse/wetland/lake. Dewatering locations must be approved by the Lead Activity Inspector and the Inspector [Section 11.2].	• Loss or alteration of wetland habitat, hydrological and biogeochemical function from the facilities during construction activities until vegetation is re-established and sedimentation is controlled.

TABLE 7.4.8-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Potential loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.,* habitat, hydrology, biogeochemistry) (cont'd)	Blackpool Kingsvale Power line	LSA	• Maintain sediment fences in place at non-peat wetland boundaries, where warranted, until a vegetation cover has stabilized the adjacent construction areas [Section 7.0]. • Adhere to the measures outlined in the Wet/Thawed Soils Contingency Plan (see Appendix B) during wet/thawed soil conditions [Section 7.0 and 8.2]. • Postpone construction, suspend equipment travel or utilize construction alternatives in the event of wet or thawed soils in order to reduce terrain disturbance and soil structure damage [Section 7.0]. • Install erosion and sediment control structures and materials (*e.g.,* subsoil berm or sediment fencing) and implement, as warranted, erosion control measures outlined in the Soil Erosion and Sediment Control Contingency Plan (see Appendix B) to ensure that sediments in surface water draining from the facility site do not adversely affect the surrounding terrain or waterbodies. In particular, control erosion on grade cuts adjacent to the development zone at facility sites [Section 7.0]. • Ensure that hydrovac slurry will not be pumped into or allowed to flow into a watercourse/wetland/lake [Section 8.1]. • Do not apply dust control suppressants to roads during windy conditions or within 300 m of a watercourse/wetland/lake [Section 9.0]. • Store mixtures of snow and soil in a manner that prevents sedimentation of watercourses/wetlands/lakes when the snow melts [Section 11.1]. • Isolate work areas in the vicinity of watercourses/wetlands/lakes to ensure water does not experience an increase in alkalinity beyond ambient conditions during construction [Section 11.2]. • Ensure that any concrete, cement, mortars or other lime-containing construction materials are not deposited, directly or indirectly, into or near any watercourse/wetland/lake. All forms, if applicable, shall be examined by qualified Inspector(s) prior to pour to ensure they are tight [Section 11.2].	• See above.

TABLE 7.4.8-1 Cont'd

Potential Effect	Pump Station Facility	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.2 Potential contamination of wetland function (*i.e.,* habitat, hydrology, biogeochemistry) due to a spill during construction	Blackpool Kingsvale Power line	LSA	• Prevent water that contacts uncured or partly cured concrete during activities such as exposed aggregate wash-off, wet curing or equipment washing from directly or indirectly entering a watercourse /wetland/lake [Section 11.2]. • Maintain the identified separation distances between the following areas and a waterbody when constructing the facility site, unless otherwise approved: - fuel or hazardous material storage site - 300 m; - cleared area - 100 m; - burning site - 100 m; - subsoil pile - 100 m; and - oil change area - 100 m. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are released on the ground or into any watercourse or wetland. In the event of a spill, implement the Spill Contingency Plan (see Appendix B) [Section 7.0]. • See additional spill prevention measures related to hazardous material storage and refuelling in Section 7.0 of the Facilities EPP.	• Reduction of wetland habitat, hydrological and biogeochemical function in the event of a spill from stored equipment during construction (depending on the volume and type of substance spilled).

Notes: 1 LSA = Wetland LSA.

2. Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.4.8.3 Potential Residual Effects

The potential residual environmental effects on the wetland indicator of the Project activities at pump station facilities (Table 7.4.8-1) are:

- loss or alteration of wetland function (*i.e.,* habitat, hydrological, biogeochemical) during and following construction activities until vegetation is re-established, grade and natural flow patterns are restored and until sedimentation is controlled; and
- reduction of wetland habitat, hydrological and biogeochemical function in the event of a spill from stored equipment during construction (depending on the volume and type of substance spilled).

7.4.8.4 Significance Evaluation of Potential Residual Effects

The quantitative analysis revealed that there are approximately 0.6 ha of potential wetland located within the Blackpool Pump Station existing boundary. However, disturbance associated with the proposed pump station facility expansions at this station are not expected to affect this wetland due to the focus of the expansion works on areas that have already been disturbed and the possibility to avoid working within the wetland boundaries during construction. For the Kingsvale power line, it is unknown at this time the exact area which may be disturbed by the power line structures until a route and placement of these structures has been finalized.

Table 7.4.8-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of the Project activities at pump station facilities on wetlands. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.4.8-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON WETLAND LOSS OR ALTERATION

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
1. Wetland Loss or Alteration – Wetland Function									
1(a) Loss or alteration of wetlands of High Functional, High-Moderate, Low-Moderate and Low Functional Condition (*i.e.,* habitat, hydrology, biogeochemistry).	Negative	LSA	Short-term	Isolated	Medium to long-term	Low	High	High	Not significant
1(b) Contamination of wetland function (*i.e.,* habitat, hydrology, biogeochemistry) due to a spill during construction.	Negative	LSA	Immediate	Accidental	Short to long-term	Low to high	Low	High	Not significant

Notes: 1 LSA = Wetland LSA.

2. Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of alteration of potential contamination of wetland function due to a spill during construction was determined to be the same for the construction and operations of Project activities at pump station facilities as for pipeline construction and operations. The exception is frequency which is isolated. Table 7.2.8-3 and the accompanying discussion in Section 7.2.8.6 provide an evaluation of potential residual effects of Project activities at pump station facilities, including power lines, and their significance on the wetland function indicator.

Wetland Loss or Alteration Indicator – Wetland Function

As with the effects assessment for the pipeline construction and operations, Project activities along power lines (*e.g.,* Kingsvale) may result in a potential loss or alteration of wetland function through a loss of wetland area. Trans Mountain will discuss any reduced function loss with Environment Canada.

Construction activities at the Blackpool Pump Station are not anticipated to affect wetland habitat function. However, construction activities at structure locations along the Kingsvale power line may potentially disturb wetland area resulting in a reduction in wetland habitat function. This is considered to have a negative impact balance. Given that many of the wetlands in the area around the proposed Kingsvale power line have been affected by existing anthropogenic disturbance, the possibility that a slight reduction in wetland area does not result in an overall loss of wetland function, and/or by fulfilling any potential compensation requirements through consultation with Environment Canada, the magnitude of the residual effect of the loss of wetland area and reduction of wetland habitat function is considered to be low. It is anticipated that this residual effect can be reversible in the long-term since wetland function will not be reclaimed until the end of the life of the operating power line. The proposed power line works could result in a reduction to the wetland footprint. Any reduction will be discussed with Environment Canada to see if compensation is required. The time for any compensation measures to become effective is conservatively estimated to be in the medium to long-term depending on the scope for the potential wetland compensation projects (Table 7.4.8-2, point 1[a]).

The construction of the proposed power line works may alter wetland hydrological function along the Kingsvale power line. The residual effect is limited to the Wetland LSA, permanent and of low magnitude. The potential changes to hydrologic flow (*i.e.,* surface or groundwater flow) of wetlands as a result of construction or operations activities at the Blackpool Pump Station and along the Kingsvale power line may include wetland drainage, water diversion and natural flow impedance. Each of these alterations is an interruption to the natural hydrologic regime and is considered an adverse environmental effect. The vertical and horizontal water movements in wetlands are easily disrupted. The hydraulic conductivity of the wetland's substrate can be affected by compaction or mixing of the soil structure. Excessive wetland drainage or diversion will result in an unnatural decrease to wetland area while flow impedance (*i.e.,* inadequate drainage) modifies or creates wetland habitat. Loss of wetland hydrological function may occur along the Kingsvale power line at structure locations, however, by fulfilling potential compensation requirements through consultation with Environment Canada wetland hydrological function will be enhanced at the chosen restoration site resulting in a reversibility of the effect of medium to long-term. The time for the compensation measures to become effective is conservatively estimated to be in the short to long-term depending on the scope for the wetland compensation projects.

Activity in or near wetlands during the proposed pump station and power line works may result in increased sediment deposition and turbidity of surface waters, thereby decreasing overall biogeochemical function. Additionally, permanent infilling is detrimental to a wetland's capacity to reduce overland flow and provide sediment retention. However, given the application of sedimentation control mitigation measures (*i.e.,* sediment fencing) for adjacent wetlands, the likelihood of alteration to nearby wetlands is reduced. Other detrimental effects regarding loss of wetland biogeochemistry capacity include the potential for loss of groundwater quality as a result of interference with shallow groundwater movement and changes to nutrient levels due to flow impedance. The impact balance of the loss of biogeochemical function is considered to be negative. With the implementation of a wetland compensation plan to be carried out through either reclamation, restoration or financial contribution, the potential loss of wetland biogeochemical function is considered to be reversible in the medium to long-term and of low magnitude.

A summary of the rationale for all of the significance criteria of effects on wetland function (*i.e.,* habitat, hydrological and biogeochemical) is provided below (Table 7.4.8-2, point 1[a]).

- Spatial Boundary: Wetland LSA – loss of wetland function (*i.e.,* habitat, hydrological and biogeochemical) resulting from pump station facility expansion.
- Duration: short-term – the events causing the loss of wetland function are construction activities.
- Frequency: isolated – loss of wetland function (*i.e.,* habitat, hydrological and biogeochemical) occurs during the construction phase of the Project.
- Reversibility: medium to long-term – loss of wetland function reversibility depends on the growth time of wetland species (medium-term) found within the restoration/enhancement site and the time for biogeochemical processes in the restoration/enhancement site to be restored/created (medium to long-term), the reversibility of the residual effect may take longer than one year with the possibility of being greater than 10 years.
- Magnitude: low – with the implementation of compensation, there will be no net loss of wetlands (for all effects).
- Probability: high – the proposed pump station facilities encounter some wetlands and disturbances within these wetlands will likely occur during construction activities at the pump stations.
- Confidence: high – based on available research literature, results of mitigation measures and post-construction environmental monitoring programs of past pipeline projects and the professional experience of the assessment team.

7.4.8.5 Summary

As identified in Table 7.4.8-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the wetland indicator of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with Project activities at pump station facilities on wetland loss or alteration will be not significant.

7.4.9 Vegetation

Sections 7.2.9.1 and 7.2.9.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of the Project activities at pump station facilities on vegetation.

7.4.9.1 Ecological Context

Activities that require clearing of land have the potential to affect vegetation. The Project includes six pump station locations that will require clearing of previously undisturbed land (*i.e.,* Gainford, Hinton, Black Pines, Kingsvale, Rearguard and Sumas). The Gainford, Sumas, Rearguard, Kingsvale and Hinton pump stations will require minimal clearing of existing trees and are located adjacent to several other disturbances such roads and existing rights-of-way. Therefore, activities at these pump stations are not expected to have a notable effect on vegetation. The Kingsvale power line and the Black Pines Pump Station and associated power line will require substantial clearing and, therefore, have the potential to affect vegetation. There are no pump stations or power lines in the BG BGC that will require clearing of previously undisturbed land. The introduction and spread of weeds has the potential to occur during any anthropogenic disturbance and, therefore, considered with all pump stations.

Section 7.2.9.3 provides further details on the ecological context for vegetation.

7.4.9.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the construction and operations of the proposed pump stations and power lines on vegetation indicators are listed in Table 7.4.9-1. These interactions are based on the results of the literature review, available research literature, desktop analysis, field work, modelling and TEK, engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0) and the professional experience of the assessment team.

The summary of mitigation measures provided in Table 7.4.9-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.9.4.

TABLE 7.4.9-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON VEGETATION

Potential Effect	Pump Station Facilities	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Vegetation Indicator – Vegetation Communities of Concern				
1.1 Alteration of native vegetation	Gainford Hinton Rearguard Black Pines Pump station Power line Kingsvale Power line	Footprint	• The proposed pump station facilities have been sited to utilize existing disturbances as much as practical and the proposed Project Footprint kept to a minimum to reduce loss of native vegetation to the maximum extent feasible. • Confine all pre-clearing/mowing and general clearing activities within the staked/flagged facility construction boundaries. Adhere to clearing restrictions associated with special environmental features and buffer areas in addition to those areas outlined in the resource-specific mitigation tables (see Appendices E to Q) [Section 8.1]. • Use hand clearing methods where directed by the Inspector to avoid or reduce disturbance to the ground surface on sensitive terrain [Section 8.1]. • Restrict root grubbing in wet areas, where practical, to avoid creation of bog holes [Section 8.1]. • Install temporary erosion control on exposed moderately to highly erodible soils where there is potential for water or wind erosion prior to re-establishment of vegetation [Section 8.4].	• Loss or alteration of the composition of 11 ha of native vegetation.

TABLE 7.4.9-1 Cont'd

Potential Effect	Pump Station Facilities	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.1 Alteration of native vegetation (cont'd)	See above	See above	• Seed the topsoil/root zone material immediately with a cereal grass cover crop species (see Section 8.0), unless otherwise directed by the Lead Activity Inspector and the Inspector, to reduce the risk of erosion [Section 11.0] • Schedule construction on native grasslands to occur when ground conditions are dry or frozen, where feasible [Section 11.0].	• See above.
1.2 Alteration of rare ecological communities	Gainford Hinton Rearguard Black Pines Pump station Power line Kingsvale Power line	LSA	• See potential effect 1.1 of this table for mitigation regarding alteration of native vegetation. • For wetland ecological communities of concern, refer to mitigation measures detailed in Table 7.4.8-1. • Upon discovery of a rare ecological community, refer to the mitigation measures provided in Rare Ecological Community and Rare Plant Population Management Plan [Appendix C, Section 4.0]. • Review mitigation measures of rare plants/rare ecological communities with Trans Mountain's Inspector(s) in advance of construction to ensure there is full understanding of the procedures involved [Section 7.0]. • Refer to environmental resource-specific mitigation tables for rare plants/rare ecological communities provided in Appendix J and as shown on the Facility Environmental Drawings.	• Some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare ecological communities are located adjacent to the pump stations they may be indirectly affected by changes in hydrology or light levels.
2. Vegetation Indicator – Plant and Lichen Species of Concern				
2.1 Loss or alteration of rare plant and/or lichen occurrences	Gainford Hinton Rearguard Black Pines Pump station Power line Kingsvale Power line	LSA	• Vegetation surveys were conducted at Gainford, Hinton, Black Pines, and Kingsvale pump stations. See Section 9.0 for details regarding supplemental surveys. • See potential effect 1.1 of this table for mitigation measures regarding alteration of native vegetation. • Flag or fence-off resource-specific environmental features (*e.g.,* rare plant species, rare ecological communities) prior to commencing construction in the vicinity of the resource site [Section 6.0]. See additional measures in Section 8.6 of the Pipeline EPP. • Water down construction sites and access roads, when warranted, to reduce or avoid the potential for dust emissions. Increase the frequency of watering roads and sites during periods of high risk (*e.g.,* high winds). Implement additional dust abatement measures (*e.g.,* covering topsoil windrows, installing sediment fences, applying a tackifier) will be implemented, when warranted, during clearing and construction activities. See additional measures to control dust in Section 8.1 of the Facilities EPP. • Recontour the landscape to pre-construction conditions during decommissioning [Section 6.0 of Appendix C].	• Some disturbance or alteration of a rare plant or lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare plant and lichen sub-populations are located adjacent to the pump stations they may be affected by changes in hydrology or light levels.

TABLE 7.4.9-1 Cont'd

Potential Effect	Pump Station Facilities	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern				
3.1 Weed introduction and spread	All	RSA	• Conduct a pre-construction weed survey at each TMEP facility site. Flag areas identified as having noxious weed infestations prior to commencement of construction [Section 6.0]. • Follow recommendations made in the pre-construction weed survey to limit the risk of spreading weed seeds [Section 6.0]. • Implement weed management (*i.e.*, using proper application of herbicides, mowing, or a combination of both) at locations identified within the pre-construction weed survey to a level that is consistent with weed management observed adjacent to the facility site to reduce the potential for weed infestations following construction. Refer to the Weed and Vegetation Management Plan provided in Appendix C [Section 6.0]. • Ensure equipment arrives at all construction sites clean and free of soil or vegetative debris. Inspect and identify equipment deemed to be in appropriate condition with a suitable marker, such as a sticker. Any equipment arriving in a dirty condition will not be allowed on-site until it has been cleaned [Section 7.0]. • Consider implementing the Weed and Vegetation Management Plan as necessary (see Appendix C) [Section 7.0]. • Immediately record any sites located outside of the facility site development zone where equipment was specifically cleaned due to concerns associated with weeds and communicate to the Inspector [Section 7.0]. • Monitor weed growth on topsoil/root zone material piles during the course of construction and conduct corrective measures (*i.e.*, spraying), if warranted [Section 7.0]. • Conduct basic shovel and sweep cleaning before moving equipment from any locations identified as having a Prohibited Noxious or Noxious weed infestation (see Weed and Vegetation Management Plan and Agriculture Management Plan in Appendix C) [Section 7.0]. • Additional mitigation measures to reduce weed growth and spread may be warranted if topsoil/root zone material replacement is delayed due to construction scheduling [Section 7.0]. • Refer to environmental resource-specific mitigation tables for vegetation provided in Appendix J [Section 7.0]. • Use only Certified Canada No. 1 or the best available agronomic seed. For native seed, the highest seed grade available will be obtained. Do not accept seed lots that contain any Prohibited Noxious or Noxious weeds as identified in the Certificate of Analysis. Retain the Certificates of Analysis obtained for both agronomic and native seed for future documentation. The Certificates of Analysis will be presented to the landowner/Crown land authority upon request [Section 8.6].	• Weed introduction and spread.

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.4.9.3 Potential Residual Effects

The potential residual environmental effects on vegetation indicators of Project activities at pump station facilities (Table 7.4.9-1) are:

- alteration of the composition of 11 ha of native vegetation;
- some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare ecological communities are located adjacent to the pump stations they may be indirectly affected by changes in hydrology or light levels;
- some disturbance or alteration of a rare plant or lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare plant or lichen sub-populations are located adjacent to the pump stations they may be affected by changes in hydrology or light levels; and
- weed introduction and spread.

7.4.9.4 Significance Evaluation of Potential Residual Effects

Table 7.4.9-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of Project activities at pump station facilities on vegetation. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.4.9-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PROJECT ACTIVITIES AT PUMP STATION FACILITIES ON VEGETATION

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Vegetation Indicator – Vegetation Communities of Concern									
1(a)	Loss or alteration of the composition of 11 ha of native vegetation.	Negative	Footprint	Short-term	Periodic	Medium to long-term	Low to medium	High	High	Not significant
1(b)	Some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Medium	Low	High	Not significant
1(c)	If rare ecological communities are located adjacent to the pump stations they may be indirectly affected by changes in hydrology or light levels.	Negative	LSA	Short-term	Isolated	Medium to long-term	Low	Low	Moderate	Not significant
2.	Vegetation Indicator – Plant and Lichen Species of Concern

				Duration	Frequency	Reversibility				
2(d)	Combined effects on the plant and lichen species of concern indicator (2[a] and 2[b]).	Negative	LSA	Short-term	Periodic	Medium to long-term	Medium	High	High	Not significant
3.	Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern									
3(a)	Weed introduction and spread.	Negative	RSA	Short-term	Periodic	Short to medium-term	Low to medium	High	High	Not significant

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of potential residual effects on most of the vegetation indicators was determined to be the same for the construction and operations of Project activities at pump station facilities as for pipeline construction and operations. The exception is the probability of the event causing the residual effects for the vegetation communities of concern indicators 1(b) and 1(c), which for the pump station facilities is considered low due to the unlikely occurrence of rare ecological communities within the footprint and LSA of the Project activities. Table 7.2.9-3 and the accompanying discussion in Section 7.2.9.6 provide an evaluation of potential residual effects of Project activities at pump station facilities, including power lines, and their significance on the applicable vegetation indicator.

7.4.9.5 Summary

As identified in Table 7.4.9-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the vegetation indicators of high magnitude that cannot be technically or economically mitigated. Consequently, is it concluded that the residual environmental effects associated with Project activities at pump stations on vegetation will be not significant.

7.4.10 Wildlife and Wildlife Habitat

Activities that require clearing of previously undisturbed lands have the potential to affect Wildlife and Wildlife Habitat. The Project includes four pump station locations that will require clearing of previously undisturbed land (*i.e.,* Gainford, Hinton, Black Pines, Kingsvale) (Table 7.4-1 in Section 7.4). The Gainford and Hinton pump stations will require minimal clearing of existing trees and are located adjacent to several other disturbances such roads and existing rights-of-way. Therefore, the habitat value at the Gainford and Hinton pump stations is expected to be low and activities are not expected to have a notable effect on Wildlife and Wildlife Habitat beyond that which is covered in the pipeline effects assessment (Section 7.2). The Black Pines and Kingsvale pump stations and their associated power lines will require substantial clearing of lands that habitat value. Therefore, activities at the Black Pines and Kingsvale pump stations and their associated power lines have the potential to affect Wildlife and Wildlife Habitat. Pump stations that will not require clearing of previously undisturbed lands are not expected to have a notable effect on Wildlife and Wildlife Habitat (*i.e.,* Edmonton, Niton, Wolf, Edson, Jasper, Rearguard, Blue River, Blackpool, Darfield, Kamloops and Sumas Pump Station).

The assessment of effects on wildlife and wildlife habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, other ancillary facilities, and the Westridge Marine Terminal), since the components will have similar effect pathways (*i.e.,* change in habitat movement and mortality risk) on wildlife indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for wildlife indicators.

The assessment of effects on wildlife and wildlife habitat for the Project as a whole is presented in Section 7.2.10. Table 7.2.10-6 and accompanying discussion in Section 7.2.10.9 provide the evaluation of potential residual effects of pump station activities on mammal indicators, Table 7.2.10-9 and accompanying discussion in Section 7.2.10.10 provide the evaluation of potential residual effects of pump station activities on bird indicators, Table 7.2.10-12 and accompanying discussion in Section 7.2.10.11 provide the evaluation of potential residual effects of pump station activities on amphibian indicators, and Table 7.2.10-15 and accompanying discussion in Section 7.2.10.12 provide the evaluation of potential residual effects of pump station activities on the reptile indicator.

7.4.11 Species at Risk

The construction and operations of Project activities at pump stations and power line may affect fish, vegetation and wildlife species at risk. Section 7.2.11 provides a discussion of the fish and wildlife species used as indicators for species at risk. Vegetation species at risk are considered under the plant and lichen species of concern indicator. Although not all species at risk are discussed explicitly under each indicator, potential Project effects were assessed in consideration of all species at risk. The indicators used to represent fish and fish habitat, vegetation and wildlife and wildlife habitat were carefully selected to ensure that the full range of potential Project effects on species at risk was addressed and measures to reduce these effects will apply to all species at risk, not just the indicators. Section 7.2.7 Fish and Fish Habitat, Section 7.2.9 Vegetation and Section 7.2.10 Wildlife and Wildlife Habitat provide the significance rationale for applicable indicator species. No significant adverse effects on species at risk have been identified as a result of the pipeline and facilities component of the Project.

7.5 Effects Assessment – Tank Installation and Operations

Preliminary assessment indicates that to accommodate the expanded pipeline operations, the Project will require a total of 20 additional tanks ranging in shell capacities from 75,000 bbl to 400,000 bbl to accommodate the expanded pipeline operations. Further study is underway to verify the number and capacities of the new tanks that are optimal to support the expanded system. The location, number and capacity of the new tanks are identified in Table 7.5-1.

TABLE 7.5-1

PROJECT TANKS AND ASSOCIATED TERMINAL WORK

Terminal	Number of New Tanks	Disturbance of Previously Undisturbed Areas	Activities
Edmonton, AB	5	No	• Four new tanks will be installed (2 x 34,980 m^3 [220,000 bbl] and 2 x 63,600 m^3 [400,000 bbl]) • An existing 12,720 m^3 (80,000 bbl) tank will be dismantled and a new 11,920 m^3 (75,000 bbl) tank will be installed • On-site access roads to each new tank • Power requirements/upgrades
Sumas, BC	1	Yes	• One new 27,820 m^3 (175,000 bbl) tank will be installed • On-site access road to the new tank • Relocate existing power line • Clearing of treed area and grading
Burnaby, BC	14	Yes (disturbance to natural watercourse within existing fenceline)	• 14 new tanks will be installed (2 x 39,750 m^3 [250,000 bbl], 10 x 45,310 m^3 [285,000 bbl] and 2 x 53,260 m^3 [335,000 bbl]) • One 12,720 m^3 (80,000 bbl) existing tank will be dismantled and replaced by one of the 45,310 m^3 (285,000 bbl) tanks • New scraper facilities for new pipeline (receiving) and Westridge delivery lines (sending) • Power requirements/upgrades will be determined by BC Hydro • On-site access roads to each new tank and other associated facilities

A detailed description of the proposed tank activities is provided in Section 2.0 of this volume and in Volume 2.

Using the assessment methodology described in Section 7.1, the following subsections evaluate the potential environmental effects arising from the construction and operations of the proposed tanks and associated terminal work.

Environmental elements potentially interacting with the construction and operations of the proposed tanks are identified in Table 7.5-2. The table also describes the rationale for those environmental elements which are not considered to interact with proposed tank activities and associated terminal work. Spatial boundaries for the assessment of pump station facilities are the same as in the applicable subsection of Section 7.2 unless otherwise noted.

TABLE 7.5-2

ELEMENT INTERACTION WITH THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK

Element	Interaction with Proposed Tanks	
	Construction	Operations[1]
Physical and Meteorological Environment	Yes	Yes
Soil and Soil Productivity	Yes	Yes
Water Quality and Quantity	Yes	Yes
Air Emissions	Yes	Yes
GHG Emissions	Yes	Yes
Acoustic Environment	Yes	Yes
Fish and Fish Habitat	Yes	Yes
Wetland Loss or Alteration	No – wetlands are not expected to be disturbed by construction of storage tanks and associated activities	No - wetlands are not expected to be disturbed operations.
Vegetation	Yes	Yes
Wildlife and Wildlife Habitat	Yes	Yes
Species At Risk	Yes	Yes

Note: 1 Activities during operations include maintenance activities and vegetation management (*e.g.*, weed control).

7.5.1 Physical and Meteorological Environment

Sections 7.2.1.1 and 7.2.1.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of proposed tanks and terminal work on the physical environment.

7.5.1.1 Physical Environment Context

Grading will be required at Burnaby and Sumas terminals in order to accommodate the storage tanks and associated infrastructure.

7.5.1.2 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with the construction and operations of storage tanks and associated terminal work were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.5.1-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.1.4.

TABLE 7.5.1-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON PHYSICAL ENVIRONMENT

Potential Effect		Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.	Physical Environment Indicator – Terrain Instability				
1.1	Terrain instability	Sumas Burnaby	LSA	• See recommended mitigation measures provided in Table 7.4.1-1 Physical Environment.	• No residual effect identified.
2.	Physical Environment Indicator – Topography				
2.1	Alteration of topography	Sumas Burnaby	LSA	• See recommended mitigation measures provided in Table 7.4.1-1 Physical Environment.	• Alteration of topography at Sumas and Burnaby terminals where grading is required.

Notes: 1 LSA = Physical Environment LSA.

2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.5.1.3 Potential Residual Effects

The potential residual environmental effect on physical environment indicators associated with storage tanks and associated terminal work is topography will be altered at Sumas and Burnaby terminals where grading is required (Table 7.5.1-1).

Potential terrain instability resulting from construction and operations of storage tanks and associated terminal work is concluded not to have a residual effect because instability potential is predicted to be eliminated through the implementation of mitigation measures (Table 7.5.1-1).

7.5.1.4 Significance Evaluation of Potential Residual Effects

Table 7.5.1-2 provides a summary of the significance evaluation of the potential residual environmental effects on physical environment indicators resulting from construction and operations of storage tanks and associated terminal work. The rationale used to evaluate the significance of the residual environmental effect is provided below.

TABLE 7.5.1-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON PHYSICAL ENVIRONMENT

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Physical Environment Indicator – Topography									
1(a)	Alteration of topography at Sumas and Burnaby terminals where grading is required.	Negative	Footprint	Short-term	Isolated	Permanent	Low	High	High	Not significant

Notes: 1 LSA = Physical Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of alteration of topography at the Sumas and Burnaby terminals (Table 7.5.1-2, point 1[a]) was determined to be the same for the construction and operations of new storage tanks as for as for pump station construction and operations (Table 7.5.1-2, point 1[a]).

Table 7.4.1-2 and the accompanying discussion in Section 7.4.1.4 provide an evaluation of this potential residual effect of new storage tanks and its significance on the applicable physical environment indicator.

7.5.1.5 Summary

As identified in Table 7.5.1-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the physical environment indicator of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with construction and operations of the proposed tanks and associated terminal work on the physical environment will be not significant.

7.5.2 Soil and Soil Productivity

Sections 7.2.2.1 and 7.2.2.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of proposed tanks and terminal work on soil and soil productivity.

7.5.2.1 Soil Context

Disturbance to soils is expected at the Sumas Terminal and Burnaby Terminal. Section 7.2.2.3 provides additional context on soils.

7.5.2.2 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with the construction and operations of the proposed tanks and associated terminal work on soil and soil productivity indicators are listed in Table 7.5.2-1. These interactions were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.5.2-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.2.4.

TABLE 7.5.2-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON SOIL AND SOIL PRODUCTIVITY

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Soil Indicator – Soil Productivity				
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging	Sumas Burnaby	Footprint	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• Mixing of topsoil/root zone material and subsoil.
1.2 Decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land	All	LSA	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• No residual effect identified.
1.3 Decreased soil productivity from soil diseases (*i.e.,* clubroot disease and potato cyst nematode)	Sumas	LSA	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• Clubroot disease introduction and spread. Potato cyst nematode introduction and spread.
2. Soil Indicator – Soil Degradation				
2.1 Degradation of soil structure due to compaction and rutting	Sumas Burnaby	Footprint	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• Degradation of soil structure and impairment of rooting zone due to compaction and rutting.
2.2 Loss of topsoil/root zone material through wind and water erosion	Sumas Burnaby	Footprint	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.

TABLE 7.5.2-1 Cont'd

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.3 Degradation of soil structure due to pulverization of soil and sod	Sumas Burnaby	Footprint	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.
2.4 Erosion of soil as a result of release of hydrostatic test water on land	All	LSA	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• No residual effect identified.
3. Soil Indicator – Soil Contamination				
3.1 Disturbance of previously contaminated soil	All	Footprint	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• No residual effect identified.
3.2 Contamination of soil as a result of hydrostatic test water on land	All	LSA	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• No residual effect identified.
3.3 Soil contamination due to spot spills during construction	All	Footprint	• See recommended mitigation measures outlined in Table 7.4.2-1 Soil and Soil Productivity.	• No residual effect identified.

Notes: 1 LSA = Soil LSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.5.2.3 Potential Residual Effects

The potential residual environmental effects on soil and soil productivity indicators of the construction and operations of the proposed tanks and associated terminal work (Table 7.5.2-1) are:

- mixing of topsoil/root zone material and subsoil;
- clubroot disease and potato cyst nematode introduction and spread;
- degradation of soil structure and impairment of rooting zone due to compaction and rutting;
- surface erosion of topsoil/root zone material can be expected until a vegetative cover is established; and
- pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.

Some of the potential effects on element indicators of the construction and operations of the proposed tanks and associated terminal work are predicted to be eliminated through the implementation of mitigation measures (Table 7.5.2-1). The potential effects determined not to have a residual effect are:

- decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land;
- erosion of soil as a result of release of hydrostatic test water on land;
- disturbance of previously contaminated soil;
- contamination of soil as a result of hydrostatic test water on land; and
- soil contamination due to spot spills during construction.

7.5.2.4 Significance Evaluation of Potential Residual Effects

Table 7.5.2-2 provides a summary of the significance evaluation of the potential residual environmental effects on soil and soil productivity indicators associated with construction and operations of the proposed tanks and associated terminal work.

TABLE 7.5.2-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON SOIL AND SOIL PRODUCTIVITY

				Temporal Context						
	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Duration	Frequency	Reversibility	Magnitude	Probability	Confidence	Significance[2]
1.	Soil Indicator – Soil Productivity									
1(a)	Mixing of topsoil/root zone material and subsoil.	Negative	Footprint	Short-term	Isolated	Long-term	Low	High	High	Not significant
1(b)	Clubroot disease and potato cyst nematode introduction and spread.	Negative	LSA	Short-term	Accidental	Long-term	High	Low	Moderate	Not significant
2.	Soil Indicator – Soil Degradation									
2(a)	Degradation of soil structure and impairment of rooting zone due to compaction and rutting.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant
2(b)	Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.	Negative	Footprint	Short-term	Isolated	Medium-term	Low	High	High	Not significant
2(c)	Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	Low to high	High	Not significant
2(d)	Combined effects on the soil degradation indicator (2[a] to 2[c]).	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant

Notes: 1 LSA = Soil LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the soil productivity indicator and soil degradation indicator (Table 7.5.2-2, points 1[a] and 1[b], and 2[a] to 2[d] respectively), was determined to be the same for the construction and operations of new storage tanks as for pump station construction and operations. The exception is the reversibility of mixing of topsoil/root zone material and subsoil (point 1[a]), which is considered long-term where topsoil is stored in berms (similar to pump stations as noted in Table 7.4.2-2). Table 7.4.2-2 and the accompanying discussion in Section 7.4.2.4 provide an evaluation of potential residual effects of the proposed tanks and associated terminal work and their significance on the applicable element indicator.

7.5.2.5 Summary

As identified in Table 7.5.2-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on soil and soil productivity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with the construction and operations of the proposed tanks and associated terminal work on soil and soil productivity will be not significant.

7.5.3 Water Quality and Quantity

Sections 7.2.3.1 and 7.2.3.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of the proposed tanks and terminal work on water quality and quantity.

7.5.3.1 Water Quality and Quantity Context

No work will occur within 30 m of any watercourses or waterbodies at the Edmonton Terminal or the Sumas Terminal. The headwaters of Eagle Creek are within the existing property boundaries of the Burnaby Terminal and will be within 30 m of planned work. Eagle Creek drains into Burnaby Lake, which flows south via the Brunette River into the Fraser River.

Water discharge volumes are not expected to increase from construction and operations of new tanks at the Edmonton Terminal. However, an incremental increase in volume of stormwater discharge is anticipated at the Sumas and Burnaby terminals. Stormwater at the Sumas Terminal is discharged into a wet area identified through desktop review to be a potential shrubby swamp associated with an ephemeral drainage (to be confirmed during supplemental studies [see Section 9.0]). Given the limited areal requirements associated with the additional tank proposed at the terminal, this area is not anticipated to be affected by any resulting incremental increases in stormwater discharge. Stormwater at the Burnaby Terminal, however, is discharged into the Eagle Creek watershed, which may experience an increase in stormwater discharge as a result of the 14 proposed storage tanks.

Hydrostatic testing is planned for the piping and new tanks to be installed within the terminals. Water may be withdrawn and released from Trans Mountain’s existing fire water ponds at the terminals. Alternatively, test water may be diverted from a nearby river, subject to obtaining a water withdrawal permit, or purchased from municipalities depending on availability from natural sources. Following testing, water will be tested for contaminants before being treated and either discharged back into the fire water pond, trucked away, or released to a natural water body or the municipal sewer system.

Alteration of natural surface drainage patterns may occur during construction and operations of the storage tanks, particularly where considerable grading is required at the Sumas and Burnaby terminals.

Section 6.1 provides additional setting information related to water quality and quantity at the Edmonton, Sumas and Burnaby terminals.

7.5.3.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with construction and operations of the proposed tanks and associated terminal work on the water quality and quantity indicators listed in Table 7.5.3-1 were based on the results of the literature review, desktop analysis, engagement with Aboriginal communities, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team. Note that no interactions between proposed tanks and associated terminal work and groundwater indicators were predicted and, consequently, no potential effects were identified.

A summary of mitigation measures provided in Table 7.5.3-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as discussed in Section 7.2.3.4.

TABLE 7.5.3-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON WATER QUALITY AND QUANTITY

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Water Quality and Quantity Indicator – Surface Water Quality				
1.1 Suspended sediment in water column	Burnaby	LSA	• Install erosion and sediment control structures and materials (*e.g.,* sediment berms) and implement, as warranted, erosion control measures outlined in the Soil Erosion and Sediment Control Contingency Plan [Appendix B]. • See recommended mitigation measures outlined in Table 7.4.3-1 Water Quality and Quantity.	• Reduction in surface water quality due to suspended sediment during construction and operations of new storage tanks at the Burnaby Terminal.
1.2 Potential contamination from stormwater discharge during operations	Edmonton Sumas Burnaby	LSA	• Ensure the stormwater management system at the facility sites is expanded to accommodate additional tanks, as applicable [Section 7.0]. • Construct and operate storage tanks and stormwater management systems in accordance with provincial and federal requirements, including the CCME *Environmental Code of Practice for Aboveground and Underground Storage Tank Systems Containing Petroleum and Allied Petroleum Products.* • Conduct all stormwater quality sampling and monitoring in compliance with existing, amended or new provincial discharge permit conditions.	• No residual effect identified.
1.3 Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water	Edmonton Sumas Burnaby	LSA	• Obtain all applicable regulatory authority approvals for water withdrawal and discharge to allow for hydrostatic testing of the facility and ensure conditions of approvals are satisfied during water withdrawal for hydrostatic testing [Section 8.3]. • Conduct hydrostatic testing activities in accordance with the *NEB OPR*, provincial legislation, Transport Canada's *Minor Works for Water Intakes* as well as the latest version of CSA Z662 and *BC Oil and Gas Waste Regulation* Section 7(2)(e), BC Reg. 254/2005 [Section 8.3]. • Collect samples of source water, hydrostatic test water and soil of the receiving environment and analyze according to the parameters listed in Water Withdrawal and Discharge Procedures Management Plan [Appendix C] [Section 8.3]. • Ensure that water trucks, if used to transport test water to the fill site, are clean [Section 8.3]. • Follow all measures outlined in the Water Withdrawal and Discharge Procedures Management Plan and in the Water Withdrawal and Discharge Form [see Appendix C] related to test water withdrawal and dewatering [Sections 8.3]. • Employ sediment reduction methods (*e.g.,* sediment mat, sediment fence, sand bag, coffer dam), where warranted, to prevent increased sedimentation or reduced water quality where excavation of a sump in the substrate of the watercourse is necessary [Section 8.3]. • Isolate test pumps, generators and fuel storage tanks with an impermeable lined dike or depression to capture and retain any spills of fuels or lubricants [Section 8.3]. • Recover all remaining water and water contaminants (*e.g.,* methanol) in tanks and return to the supplier or dispose of contaminated test water at approved sites/facilities [Section 8.3]. • Recover methanol or methanol/water mix, if used, and return to supplier or dispose of in accordance with appropriate government legislation. Ensure the method and location of disposal has been approved by Trans Mountain and is in accordance with applicable legislation [Section 8.3].	• Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water.

TABLE 7.5.3-1 Cont'd

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.3 Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water (cont'd)	See above	LSA	• Ensure that if test water contains chemical additives, the test water is sampled and treated, if warranted, and discharged in accordance with applicable federal and provincial requirements directed by the appropriate regulatory authority [Section 8.3]. • Dewater onto approved areas where water will be filtered through vegetation and soils before returning to a watercourse/wetland/lake. Provide scour protection (*e.g.,* use of rock aprons, plastic sheeting, plywood, straw bales) or an energy diffuser (*e.g.,* cone with baffles, frog's foot) at the discharge site as directed by Trans Mountain. The rate of discharge will be reduced if these measures are ineffective [Section 8.3]. • See Section 7.5.2 Soil and Soil Productivity for discussion on the release of hydrostatic test water on land. • See Section 7.2.5 Infrastructure and Services of Volume 5B for discussion on potential effect of withdrawal of hydrostatic test water on downstream water users.	• See above.
1.4 Reduction of surface water quality due to small spill during construction	Edmonton Sumas Burnaby	LSA	• See recommended mitigation measures outlined in Table 7.4.3-1 Water Quality and Quantity.	• Contamination of surface water due to a small spill during construction.
2. Water Quality and Quantity Indicator – Surface Water Quantity				
2.1 Localized alteration of natural surface drainage patterns during construction and operations	Edmonton Sumas Burnaby	LSA	• Provide surface drainage of adequate capacity across the facility site and other Project-related facilities [Section 7.0]. • Install drainage features that ensure no off-site originating runoff will be allowed to enter the proposed development area [Section 7.0]. • Inspect all water conveyance installations (*e.g.,* ditches and culverts) and ensure they are functioning appropriately. Take appropriate action prior to and during the spring freshet to clear culverts blocked by ice or debris [Section 7.0]. • Discharge runoff from stormwater containment ponds in compliance with maximum authorized rates of discharge as per existing provincial permit conditions. • See recommended mitigation measures outlined in Table 7.4.3-1 Water Quality and Quantity.	• Localized alteration of natural surface drainage patterns at the Edmonton, Sumas and Burnaby terminals. • Localized alteration of natural streamflow patterns at the Burnaby Terminal. • Localized alteration of natural streamflow patterns downstream of the Burnaby Terminal.

Notes: 1 LSA = Water Quality and Quantity LSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.5.3.3 Potential Residual Effects

The potential residual environmental effects on water quality and quantity indicators of the construction and operations of the proposed tanks and associated terminal work (Table 7.5.3-1) are:

- reduction in surface water quality due to suspended sediment during construction and operations of new storage tanks at the Burnaby Terminal;
- alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water;
- contamination of surface water from a small spill during construction;
- localized alteration of natural surface drainage patterns at the Edmonton, Sumas and Burnaby terminals;
- localized alteration of natural streamflow patterns at the Burnaby Terminal; and

- localized alteration of natural streamflow patterns downstream of the Burnaby Terminal.

Potential contamination from stormwater discharge during operations is concluded not to have a residual effect because contamination potential is predicted to be eliminated through the implementation of mitigation measures (Table 7.5.3-1).

7.5.3.4 Significance Evaluation of Potential Residual Effects

Table 7.5.3-2 summarizes the significance evaluation of the potential residual environmental effects on water quality and quantity indicators associated with construction and operations of the proposed tanks and associated terminal work.

TABLE 7.5.3-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON WATER QUALITY AND QUANTITY

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Water Quality and Quantity Indicator – Surface Water Quality									
1(a)	Reduction in surface water quality due to suspended sediment during construction and operations of new storage tanks at the Burnaby Terminal.	Negative	LSA	Short-term	Isolated to occasional	Immediate to short-term	Low	High	High	Not significant
1(b)	Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water.	Negative	LSA	Short-term	Isolated	Immediate to short-term	Low	Low	High	Not significant
1(c)	Contamination of surface water due to a small spill during construction.	Negative	LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
2.	Water Quality and Quantity Indicator – Surface Water Quantity									
2(a)	Localized alteration of natural surface drainage patterns at the Edmonton, Sumas and Burnaby terminals.	Negative	LSA	Short-term	Isolated to occasional	Short to long-term	Low	High	High	Not significant
2(b)	Localized alteration of natural streamflow patterns at the Burnaby Terminal.	Negative	LSA	Short-term	Continuous	Permanent	Medium	High	High	Not significant
2(c)	Localized alteration of natural streamflow patterns downstream of the Burnaby Terminal.	Negative	RSA	Immediate to short-term	Periodic	Medium-term to permanent	Low	Low	Moderate	Not significant
2(d)	Combined effects on the surface water quantity indicator (2[a] and 2[b]).	Negative	LSA	Short-term	Isolated	Short-term to permanent	Low to medium	High	High	Not significant

Notes: 1 LSA = Water Quality and Quantity LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water and contamination of surface water due to a spill during construction was determined to be the same for the construction and operations of new storage tanks as for new pipeline segments (Table 7.5.3-2, points 1[b] and 1[c]). Table 7.2.3-3 and the accompanying discussion in Section 7.2.3.6 provide an evaluation of these potential residual effects of new storage tanks and their significance on the surface water quality indicator. In addition, evaluation of significance of reduction in surface water quality due to suspended sediment during construction and operations of new storage tanks at the Burnaby Terminal and localized alteration of natural surface drainage patterns at the Edmonton, Sumas and Burnaby terminals was determined to be the same as pump station construction and operations (Table 7.5.3-2, points 1[a] and 2[a]). The exception is the duration of the event which for tanks is considered to be short-term. Table 7.4.3-2 and the accompanying discussion in Section 7.4.3.4

provide an evaluation of these potential residual effects of new storage tanks and their significance on the applicable water quality and quantity indicator. The rationale used to evaluate the significance of each of the remaining residual environmental effects is provided below.

Water Quality and Quantity Indicator – Surface Water Quantity

The following provides the evaluation of significance of potential residual effects on the surface water quantity indicator.

Alteration of Natural Streamflow Patterns at the Burnaby Terminal

In order to avoid new disturbance beyond the existing Trans Mountain property, installation of the proposed 14 new storage tanks will result in permanent alteration of natural streamflow patterns of a segment of upper Eagle Creek and a number of its smaller tributaries located within the existing property. The impact balance of this potential residual effect is considered negative since it will alter or disrupt natural above ground hydrologic conditions at the Burnaby Terminal.

The current proposed diversion method is to expand the existing below ground conveyance system for Eagle Creek and its tributaries to accommodate new storage tanks at the north end of the Trans Mountain property. During a City of Burnaby Integrated Stormwater Management Visionary Workshop for Eagle Creek Watershed held in November 2012, a member of the Eagle Creek Streamkeepers Society voiced preference for an above ground conveyance system that reproduces more natural flow regimes. However, expanding the existing below ground water conveyance system was deemed the least impact approach to constructing and operating the proposed new storage tanks in the Eagle Creek watershed. Furthermore, expanding the below ground system was deemed to have the least risk to downstream water quality in the event of an accidental leak or spill during normal terminal operations.

During decommissioning and abandonment of the Burnaby Terminal, reclamation of upper Eagle Creek and its affected tributaries will be conducted with the goal of restoring natural streamflow patterns to be similar to pre-construction conditions. Recognizing complete restoration to exact pre-construction conditions will not be feasible. The residual effect is considered permanent, however, the effect is considered to be consistent with permit conditions and, therefore, is of medium magnitude (Table 7.5.3-2, point 2[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – although alteration of natural streamflow patterns is generally confined to the disturbed portion of the Burnaby Terminal, potential changes in hydrology may extend beyond the terminal.
- Duration: short-term – the event causing alteration of natural streamflow is construction of the storage tanks.
- Frequency: continuous – alteration of natural streamflow in a below ground system will occur continuously during operations.
- Reversibility: permanent – although natural streamflow patterns will be re-established following decommissioning and abandonment, complete restoration to pre-Project conditions will not be possible.
- Magnitude: medium – the existing draining system will be expanded within existing Trans Mountain property, thereby reducing the overall effects to the watershed until natural streamflow patterns are restored similar to pre-construction conditions during decommissioning and abandonment.
- Probability: high – installation of culverts to direct flow will affect natural streamflow patterns.
- Confidence: high – based on operations of the existing conveyance systems to date at the Burnaby Terminal and the professional experience of the assessment team.

Alteration of Natural Streamflow Patterns Downstream of the Burnaby Terminal

During a City of Burnaby Integrated Stormwater Management Visionary Workshop for Eagle Creek Watershed held in November 2012, maintaining natural flow regimes and reducing the magnitude of flash discharge events was emphasized as an important aspect to reduce erosion and sedimentation and maintain or enhance watershed health. Construction of the additional proposed new storage tanks has the potential to reduce capacity of the watershed to store rainwater, thereby contributing to altered natural streamflow patterns of Eagle Creek downstream of the Burnaby Terminal. The impact balance of this potential residual effect is considered negative since it may alter or disrupt natural above ground hydrologic conditions downstream of the Burnaby Terminal.

Runoff from the Burnaby Terminal may potentially increase from vegetation loss, construction of new asphalt road surfaces and the addition of impermeable liners for tank secondary containment. The resulting reduced storage capacity of the watershed to store rainwater at the terminal has the potential to contribute to increased erosion and sedimentation along Eagle Creek downstream of the terminal during flash discharge events. Although the amount of stormwater discharge is expected to increase as a function of increased disturbance and development at the Burnaby Terminal, no considerable increase in the rate of stormwater discharge from the existing stormwater containment pond is anticipated. The potential for increased discharge rates from the stormwater containment pond will be determined during the detailed engineering and design phase of the Project.

Trans Mountain will incorporate expansion of the Burnaby Terminal into its existing stormwater monitoring program, whereby Trans Mountain will continue to monitor flash drainage events in an effort to identify potential effects and implement necessary measures to reduce or avoid Project-related effects to the Eagle Creek watershed. Consequently, any increased discharge volumes resulting from construction of the new storage tanks will comply with permit conditions and, therefore, is considered to be of low magnitude (Table 7.5.3-2, point 2[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity RSA – alteration of natural streamflow patterns extend downstream of the Burnaby Terminal.
- Duration: immediate to short-term – the event causing alteration of natural streamflow is flash discharge events intensified from operations of the terminal, which may on occasion extend beyond two days.
- Frequency: periodic – the event causing alteration of natural streamflow (*i.e.,* flash discharge events from operations of the terminal) occurs intermittently but repeatedly during operations.
- Reversibility: medium-term to permanent – downstream alteration of natural streamflow patterns may cause permanent alteration to the watercourse unless restoration measures are implemented at identified areas.
- Magnitude: low – overall changes in downstream streamflow patterns resulting from increased discharge from the terminal are expected to be minimal.
- Probability: low – increased discharge resulting from expansion of the terminal is not anticipated to substantively contribute to alteration of downstream streamflow patterns.
- Confidence: moderate – based on current observations at the existing terminal and the professional experience of the assessment team, and pending determination of containment pond discharge rates during the detailed engineering and design phase of the Project.

Combined Effects on Surface Water Quantity

The combined effects evaluation considers the individual potential residual effects evaluated in Section 7.5.3.4 (points 2[a] and 2[b] of Table 7.5.3-2) that are likely to occur, and could act in combination on the surface water quantity indicator.

The following potential residual effects are likely to act in combination to result in overall effects on the surface water quantity indicator:

- localized alteration of natural surface drainage patterns at Edmonton, Sumas and Burnaby terminals; and

- localized alteration of natural streamflow patterns at the Burnaby Terminal.

The adverse effects identified have the potential to act in combination to affect surface water quantity at the Burnaby Terminal. The reversibility of this residual effect is considered short-term to permanent; short-term where construction workspace is required and full restoration is possible following construction, and permanent where complete restoration to pre-Project conditions may be difficult where considerable drainage pattern and streamflow alteration is required for operations. The magnitude of the combined effects on the surface water quantity indicator is considered to be low to medium since the combined effect is localized and will be reduced to the extent feasible through implementation of mitigation measures (Table 7.5.3-2, point 2[d]). A summary of the rationale for all of the significance criteria of combined effects on surface water quantity is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – although alteration of surface drainage and streamflow patterns is generally confined to the disturbed portion of the Burnaby Terminal, potential changes in hydrology may extend beyond the terminal.
- Duration: short-term – the event causing alteration of natural streamflow is construction of the storage tanks.
- Frequency: isolated – the event causing the combined effects on the surface water quantity indicator (*i.e.,* terminal construction) will occur during construction.
- Reversibility: short-term to permanent – short-term where construction workspace is required and full restoration is possible following construction, and permanent where complete restoration to pre-Project conditions may be impossible where alteration of natural drainage and streamflow patterns is required for operations.
- Magnitude: low to medium – although the combined effect on the surface water quantity indicator will be reduced to the extent feasible through implementation of mitigation measures, natural drainage and streamflow patterns will not be restored similar to pre-construction conditions until decommissioning and abandonment.
- Probability: high – installation of culverts and permanent above ground structures will affect surface drainage and natural streamflow patterns.
- Confidence: high – based on operations of the existing conveyance systems to date at the Burnaby Terminal and the professional experience of the assessment team.

7.5.3.5 Summary

As identified in Table 7.5.3-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the water quality and quantity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with construction and operations of the proposed tanks and associated terminal work on water quality and quantity will be not significant.

7.5.4 Air Emissions

7.5.4.1 Assessment Indicators and Measurement Endpoints

The selection of indicators for air emissions considered: filing requirements in the NEB *Filing Manual*; experience gained during previous projects with similar conditions/potential issues; initial feedback from Aboriginal engagement, landowners, regulatory authorities, stakeholders and the general public; available research literature; and the professional judgment of the assessment team. The assessment indicators and measurement endpoints used for the air emissions assessment for tank installation and operation are summarized in Table 7.5.4-1. The proposed air emission indicators were discussed during the Edmonton, Kamloops and Surrey ESA Workshops. There was general consensus among workshop participants that the proposed air emissions indicators were appropriate for evaluating effects of tank installation and operation on air emissions. Consideration was also given to Canadian National Ambient Air Quality Objectives, Canadian Ambient Air Quality Standards, Provincial Ambient Air Quality Objectives of Alberta and BC, and World Health Organization Guidelines. Input on indicator selection was sought from Environment Canada, BC MOE, FVRD, Metro Vancouver and PMV (Section 3.0); no additional indicators were suggested for consideration in assessment of tank installation and operation.

Both quantitative and qualitative measurement endpoints were applied to assess potential effects of tank installation and operation on the air emissions indicators. During tank installation, construction equipment will emit CACs including VOCs. During tank operations, Project-related CAC emissions are less than 50 gram per year, and H_2S and mercaptans emissions are also small (Table 7.2.4-2 in Section 7.2.4.3). The main emissions during tank operations are fugitive VOCs.

In addition to these direct emissions from tank operations, secondary pollutants will be formed from reactions between primary pollutants in the atmosphere. In the presence of sunlight, precursors such as NO_X and VOCs undergo a complex sequence of reactions to form ozone (O_3). In addition, secondary PM can be formed from reactions between NO_X, SO_X and ammonia (NH_3). Primary and secondary PM can absorb and scatter sunlight, causing haze and obscuring visibility. No modelling of secondary pollutant formation was performed for construction activities. During operations of tanks, only fugitive VOC emissions are anticipated to be released, and therefore, no effects on secondary PM and visibility are expected.

Advanced photochemical modelling was performed to estimate the difference in the formation of secondary PM and ozone between existing emissions and total emissions after the addition of Project related: CAC and VOC emissions in the LFV from increased shipping; fugitive emissions at tanks in the Burnaby and Sumas terminals; and CAC emissions from equipment and fugitive emissions from loading products on ships and tank storage at the Westridge Marine Terminal. Note that the chemical interaction between primary pollutants and the formation of secondary ozone is non-linear, in particular, are not additive. It is therefore not possible to determine the contribution of tank operations, only, to overall ozone formation in the LFV.

TABLE 7.5.4-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR AIR EMISSIONS FROM TANK INSTALLATION AND OPERATION

Air Emissions Indicators	Measurement Endpoint	Rationale for Indicator Selection
Primary emissions of criteria air contaminants and speciated volatile organic compounds	• Emissions from tank construction and comparison to existing emissions • Emissions from increased storage tanks and comparison to emissions from existing storage tanks • Predicted levels of ground-level concentrations and comparison to ambient air quality criteria	The selection of indicators and measurement endpoints considered NEB *Filing Manual* requirements for air emissions in Table A-2, addressed concerns raised by participants of the ESA Workshops and were informed by regulators (*i.e.*, Environment Canada, BC MOE, Metro Vancouver, FVRD, PMV).
Formation of secondary ozone	• Predicted levels of ambient ground-level ozone concentrations and comparison to ambient air quality criteria	
Hydrogen sulphide (H_2S) and mercaptans emissions which have the potential to cause nuisance odours	• Predicted levels of ambient ground-level concentrations and comparison to odour detection thresholds	

7.5.4.2 Spatial Boundaries

The spatial boundaries for the study areas for primary pollutant emissions, secondary formation of PM2.5 and ozone, and visibility are provided in Section 7.2.4.2.

7.5.4.3 Project Associated Air Emissions

Estimated air emissions from tank installation and operation (net change from existing conditions) are described in Section 7.2.4.3 and summarized in Table 7.2.4-2.

7.5.4.4 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects that are associated with the construction and operations of the proposed tanks and associated terminal work on air emissions listed in Table 7.5.4-2 were based on the results of the desktop analysis, field work, modelling, consultation with regulatory authorities, stakeholders, and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of the mitigation measures provided in Table 7.5.4-2 was principally developed in accordance with Trans Mountain standards, accepted facility construction methods for construction-related activities, and preliminary design engineering, where emission control techniques (TVAUs) were identified to reduce fugitive emissions of H_2S and VOCs at the Sumas and Burnaby terminals.

TABLE 7.5.4-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON AIR EMISSIONS

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds				
1.1 Primary emissions of criteria air contaminants	All	RSA	• Trans Mountain will consult with and inform landowners of the potential to be affected by emissions from construction activities prior to commencement of these activities in proximity to the respective landowners [Section 7.0]. • Restrict the duration that vehicles and equipment are allowed to sit and idle to less than one hour unless air temperatures are less than 0°C [Section 7.0]. • Ensure equipment is well-maintained during construction to minimize air emissions [Section 7.0]. • Use multi-passenger vehicles for the transportation of crews to and from the job sites, where feasible [Section 7.0].	• Increase in ambient ground-level concentrations of CACs during construction of storage tanks.
1.2 Primary emissions of volatile organic compounds	All	RSA	• Install TVAUs at Sumas and Burnaby terminals. • All Project-related storage tanks are required to adhere to CCME standards that will reduce fugitive VOC emissions.	• Fugitive emissions released to atmosphere create increase in ambient ground-level concentrations of VOCs.
2. Air Emissions Indicator – Formation of Secondary Particulate Matter and Ozone				
2.1 Formation of secondary ozone	Sumas Burnaby	LFV	• All Project-related storage tanks are required to adhere to CCME standards that will reduce air emissions.	• Increase in ambient ground-level concentrations of ozone.
3. Air Emissions Indicator – Hydrogen Sulphide and Mercaptans Emissions				
3.1 Emissions of H_2S and mercaptans	All	RSA	• Install TVAUs at Sumas and Burnaby. • All Project-related storage tanks are required to adhere to CCME standards that will reduce fugitive VOC emissions.	• Increase in ambient ground-level concentrations of H_2S and mercaptans.

Notes: 1 RSA = Air Quality RSA; LFV= Lower Fraser Valley.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).
3 Only Sumas and Burnaby terminal related emissions were modelled in the CMAQ model, because emissions from other terminals will not contribute to secondary ozone formation in the LFV, but mitigation measures and residual effects apply to all Project-related terminals.

7.5.4.5 Potential Residual Effects

The potential residual environmental effects on air emission indicators of the construction and operations of proposed tanks and associated terminal work (Table 7.5.4-2) are:

- an increase in ambient ground-level concentrations of CACs during construction of storage tanks;
- fugitive emissions released to the atmosphere create an increase in ambient ground-level concentrations of VOCs;
- an increase in ambient ground-level concentrations of ozone; and
- an increase in ambient ground-level concentrations of H_2S and mercaptans.

7.5.4.6 Significance Evaluation of Potential Residual Effects

A combination of a quantitative and qualitative assessment of air emissions was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects. Emissions from Project activities during the construction phase were estimated using available information (Table 7.2.4-2). A qualitative assessment of air emissions during maintenance activities was considered appropriate given the short duration of these activities and anticipated volumes of emissions, relying on the professional judgment of the assessment team.

No significant emissions of CACs are expected during tank operations; hence, dispersion modelling for CACs was not performed. Table 7.5.4-3 presents dispersion modelling results of increases in ambient concentrations of VOCs from Project-related tank operation at Edmonton, Sumas, and Burnaby terminals. Applicable regulatory objectives are available for Edmonton only (Alberta Ambient Air Quality Objectives, AESRD 2013b). These are shown to facilitate the evaluation of the magnitude of the increases in ambient ground-level concentrations of of VOCs. Increases are small and do not approach regulatory standards where available. Therefore, the magnitude for the residual effect is evaluated as low. Given similarly low predictions for Sumas and Burnaby and in the absence of applicable objectives, the same assessment of low magnitude was applied.

TABLE 7.5.4-3

DISPERSION MODELLING RESULTS FOR AMBIENT VOC CONCENTRATIONS FOR EMISSIONS FROM TANK OPERATION AND COMPARISON WITH APPLICABLE REGULATORY STANDARDS (EXPRESSED AS NET CHANGE FROM EXISTING CONDITIONS) (in µg/m^3)

Terminal	Pollutant	Averaging Period	Project	Objective[1]
Edmonton	Benzene	1-hour	0.25	30
		Annual	0.01	3
	Ethylbenzene	1-hour	0.02	2,000
	Toluene	1-hour	0.23	1,880
		24-hour	0.16	400
	Xylenes	1-hour	0.098	2,300
		24-hour	0.061	700
Sumas	Benzene	1-hour	0.09	N/A[2]
		Annual	-4.1E-07	N/A
	Ethylbenzene	1-hour	0.01	N/A
	Toluene	1-hour	0.07	N/A
		24-hour	0.02	N/A
	Xylenes	1-hour	0.02	N/A

Burnaby	Benzene	1-hour	1.69	N/A
		Annual	0.02	N/A
	Ethylbenzene	1-hour	0.50	N/A
	Toluene	1-hour	7.10	N/A
		24-hour	1.42	N/A
	Xylenes	1-hour	2.42	N/A
		24-hour	0.48	N/A

Notes: 1 Alberta Ambient Air Quality Objectives (AESRD 2013b).
2 N/A: not available.

Table 7.5.4-4 presents the results of photochemical modelling of secondary ozone and $PM_{2.5}$ and visibility. Shown are the differences between model predictions with combined emissions from increased Project-related marine vessel traffic and operations at Burnaby, Sumas and Westridge Marine Terminals and without these emissions sources. The values provided are spatial maxima over all land-based receptors. Concentration increases of ozone and $PM_{2.5}$ are small compared to current and future applicable standards; therefore their magnitude is rated low. No standard is applicable to visibility. A visibility reduction of one deciview (dv) is small but noticeable in a pristine environment with very good visibility (Colls and Tiwary 2009). The predicted visibility reduction of 3.9 dv in Table 7.5.4-4 is likely noticeable in the LFV, and a conservatively high assessment of medium magnitude was chosen.

TABLE 7.5.4-4

PHOTOCHEMICAL MODELLING RESULTS OVER LAND FOR OZONE, $PM_{2.5}$, AND VISIBILITY FOR COMBINED EMISSIONS FROM INCREASED PROJECT-RELATED MARINE VESSEL TRAFFIC AND OPERATIONS AT BURNABY, SUMAS, AND WESTRIDGE MARINE TERMINAL (EXPRESSED AS NET CHANGE FROM EXISTING CONDITIONS) AND COMPARISON WITH APPLICABLE REGULATORY STANDARDS

	Predicted[1]	Canada Wide Standard (2010)	CAAQS (2015)	CAAQS (2020)
Ozone (maximum rolling 8-hour average in ppb)[2]	0.3	65	63	62
$PM_{2.5}$ (maximum 24-hour average in µg/m^3)[3]	0.1	30	28	27
Visibility (maximum 1-hour in deciview[4])	3.9	N/A	N/A	N/A

Notes:
1 Maximum increase over land in the LFV predicted from Community Multiscale Air Quality (CMAQ) modelling of a ten-day episode of strong secondary formation from June 24 to July 3, 2006, caused by Project emissions.
2 Metric in Canada Wide Standard and Canadian Ambient Air Quality Standards (CAAQS) is the 3-year average of the annual 4th highest daily maximum 8-hour average concentrations.
3 Metric in Canada Wide Standard and CAAQS is the 3-year average of the annual 98th percentile of the daily 24-hour average concentrations.
4 The deciview or dv is unitless. The deciview scale is linear in relation to humanly perceived changes in visibility due to changes in air quality. For example a 400 km visual range corresponds to 0.0 dv, while a 4 km visual range is about 46 dv.

A quantitative assessment was performed for H_2S and mercaptans on the basis of dispersion modelling and odour detection thresholds. 3-minute and 10-minute averages for H_2S and total mercaptans, respectively, were calculated by scaling predictions of maximum 1-hour average ambient ground-level concentrations. The results for each terminal are presented in Table 7.5.4-5. No exceedances of odour detection thresholds are predicted.

TABLE 7.5.4-5

DISPERSION MODELLING RESULTS FOR H_2S AND TOTAL MERCAPTANS FOR TANK OPERATION (EXPRESSED AS NET CHANGE FROM EXISTING CONDITIONS) (in µg/m^3)

Component or Facility	H_2S Modelled Maximum 3-minute[2]	Total Mercaptans Modelled Maximum[1] 10-minute[2]
Edmonton[3]	0.0118	0.047
Sumas	0.0004	0.018
Burnaby	0.0108	0.024
Odour detection threshold	*13.1*[4]	*13*[4]

Notes:
1 No individual species within the chemical group of mercaptans nor other additional species were predicted to exceed known odour detection thresholds (see the Air Quality and Greenhouse Gas Technical Report of Volume 5C for further information).
2 3-minute and 10-minute averages were calculated from 1-hour modelled data based on the model guideline for Ontario (Ontario ministry of Environment [MOE] 2009).
3 9th highest Concentrations were used in lieu of 1-hour maximum concentrations based on the model guideline for Alberta (AESRD 2013a).
4 Odour detection threshold for H_2S is the geometric mean air odour detection threshold reported by AIHA (1989) and Total Mercaptans threshold is based on the Ontario Air Standard for Total Reduced Sulphur (Ontario MOE 2007).

Table 7.5.4-6 provides a summary of the significance evaluation of the potential residual environmental effects on air emissions indicators associated with construction and operation of the proposed tanks and associated terminal work.

TABLE 7.5.4-6

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON AIR EMISSIONS

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
1.	Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds									
1(a)	Increase in ambient ground-level concentrations of CACs during construction of storage tanks.	Negative	RSA	Short-term	Isolated	Short-term	Low	High	Moderate	Not significant

1(c)	Combined effects on the primary emissions of CACs and VOCs indicator (1[a] and 1[b]).	Negative	RSA	Long-term	Continuous	Long-term	Low	High	Moderate	Not significant
2.	Air Emissions Indicator – Formation of Secondary Particulate Matter and Ozone									
2(a)	Increase in ambient ozone concentrations.	Negative	LFV	Long-term	Continuous	Long-term	Medium	High	Moderate	Not significant
3.	Air Emissions Indicator – Hydrogen Sulphide and Mercaptans Emissions									
3(a)	Increase in ambient ground-level concentrations of H_2S and mercaptans.	Negative	RSA	Long-term	Continuous	Long-term	Low	High	Moderate	Not significant

Notes: 1 RSA = Air Quality RSA; LFV= Lower Fraser Valley.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds

The following provides the evaluation of significance of potential residual effects on the CACs and VOCs indicator.

Increase in Ambient Ground-level Concentrations of CACs During Construction of Storage Tanks

The increase in ambient ground-level concentrations of CACs is considered to have a negative impact balance. As shown in Table 7.5.4-6 point 1(a), the increase in ambient ground-level concentrations of CACs from construction is confined to the Air Quality RSA. Air emissions are expected to change ambient concentrations of CACs only during storage tank construction, therefore, the frequency is rated as isolated. The increase in CAC concentrations is likely measurable but small compared to BC and Alberta ambient objectives. Therefore, the magnitude is expected to be low. The probability of this occurring is high, because the construction equipment will emit CACs. Since the cause-effect relationships are well understood but detailed information on Project-specific construction equipment is unavailable, the confidence in the residual effects assessment is moderate. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Air Quality RSA – changes to ambient ground-level concentrations of CACs from construction are expected to occur within the Air Quality RSA.
- Duration: short-term – the event resulting in emissions of CACs is storage tank installation which is limited to the construction phase of the Project.

- Frequency: isolated – the event resulting in emissions of CACs (*i.e.*, storage tank construction) is confined to a specific period.
- Reversibility: short-term – emissions of CACs will cease and increases in ambient ground-level concentrations will reverse within a few days at the end of the tank construction.
- Magnitude: low – the increase in ambient ground-level concentrations of CACs is expected to be small relative to existing conditions and not expected to approach regulatory limits.
- Probability: high – storage tank construction will result in emissions of CACs.
- Confidence: moderate – residual effects assessment is based on a good understanding of cause-effect relationships between construction and air emissions but reliant on vehicle and equipment estimates from previous projects.

Fugitive Tank Emissions Released to Atmosphere Create Increase in Ambient Ground-level Concentrations of VOCs

The increase in ambient ground-level concentrations of VOCs is considered to have a negative impact balance. As shown in Table 7.5.4-6 point 1(b), the increase in ambient ground-level concentrations of VOCs is confined to the Air Quality RSA. Emissions are expected to change ambient VOC concentrations continuously in the RSA due to the handling and storage of product. As shown in Table 7.5.4-3, the increase of VOC concentrations is likely measureable, but the only applicable objectives for Edmonton Terminal in Alberta are not approached at any terminal. Therefore, the change is considered to be of low magnitude. The residual effect will extend for more than 10 years over the life of the operating terminal and is, therefore, reversible in the long-term. The probability of this occurring is high, because fugitive emissions will occur. The cause-effect relationships are well understood and estimations of VOC emissions were based on design information for the Project. Therefore, confidence in the residual effects assessment is high. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Air Quality RSA – changes to ambient ground-level concentrations of VOCs are expected to occur within the Air Quality RSA.
- Duration: long-term – fugitive emissions of VOCs and subsequent changes to ambient ground-level concentrations are expected to occur for the life of the operating facility and, therefore, are considered long-term.
- Frequency: continuous – fugitive emissions of VOCs will occur continuously throughout the operations phase due to working and standing losses of product.
- Reversibility: long-term – fugitive emissions of VOCs during operations at the terminals will extend over the operational life of the terminal. Fugitive emissions of VOCs cease when the facility is decommissioned.
- Magnitude: low – the increase in ambient ground-level concentrations of VOCs is expected to be small relative to existing conditions and not expected to approach regulatory limits.
- Probability: high – an increase in Project volumes of product being handled and stored will result in an increase in emissions of VOCs.
- Confidence: high – based on a good understanding of cause-effect relationships between the Project and air emissions.

Combined Effects of Tanks on Primary Emissions of CACs and VOCs

The increase in ambient ground-level concentrations of CACs and VOCs during tank installation and operation is considered to have a negative impact balance. As shown in Table 7.5.4-6 point 1(c), the combined increase in ambient ground-level concentrations of CACs and VOCs is confined to the Air Quality RSA. Emissions are expected to change ambient VOC concentrations continuously in the Air Quality RSA due to the handling and storage of product. The change is considered to be of low magnitude and reversible in the long-term. The probability of this occurring is high, and the confidence in the residual effects assessment is moderate, because Project-specific equipment information was not available for tank installation. A summary of the rationale for all of the significance criteria of combined effects on CACs and VOCs is provided below.

- Spatial Boundary: Air Quality RSA – combined effects on CACs and VOCs are expected to occur within the Air Quality RSA.
- Duration: long-term – combined effects on CACs and VOCs and subsequent changes to ambient ground-level concentrations are expected to occur for the operational life of the terminals and, therefore, are considered long-term.
- Frequency: continuous – the combined effects on CACs and VOCs reflect the fugitive emissions of VOCs which occur continuously due to working and standing losses of product.
- Reversibility: long-term – combined effects on CACs and VOCs reflect fugitive emissions of VOCs during operations at the terminals which will extend for the life of the operating terminal. Combined emissions are reversible as the fugitive emissions will cease when the facility is decommissioned.
- Magnitude: low – the combined effects on CACs and VOCs are expected to be small relative to existing conditions and not expected to approach regulatory limits.
- Probability: high – storage tank construction will result in emissions of CACs, and an increase in Project volumes of product being handled and stored will result in an increase in emissions of VOCs only.
- Confidence: moderate – based on a good understanding of cause-effect relationships between the Project and air emissions, but for tank construction it is reliant on vehicle and equipment estimates from previous projects.

Air Emissions Indicator - Formation of Secondary Particulate Matter and Ozone

The following provides the evaluation of significance of potential residual effects of tanks on the formation of secondary PM and ozone indicator.

Increase in Ambient Ozone Concentrations

The increase in ambient ground-level concentrations of ozone is considered to have a negative impact balance. As shown in Table 7.5.4-6 point 2(a), the increase in ambient ground-level concentrations of ozone is confined to the LFV photochemical model domain. Fugitive VOC emissions during tank operation will contribute chemical precursors for secondary pollutants continuously due to product working and standing losses from handling and storage. The photochemical modelling results in Table 7.5.4-3 show a small increase in ambient ground-level concentrations of ozone relative to existing concentrations; however, since monitoring stations in the eastern part of the Lower Fraser Valley show ozone concentrations close to Canadian Ambient Air Quality Standards, the increase of ambient ground-level concentrations is interpreted as approaching the standard and, therefore, considered to be of medium magnitude. Since the residual effect continues over the life of the operating terminal, reversibility is long-term. The probability of this occurring is high, because the photochemical modelling suggests that there will be an increase in ambient ground-level ozone concentrations as a result of increased precursor emissions in the LFV. Confidence in the residual effects assessment is moderate; while the assessment is based on a good understanding of cause-effect relationships between the Project, air emissions, and atmospheric reactions, there is uncertainty with respect to non-Project emissions, and atmospheric chemical reactions are complex. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: LFV – changes to ambient ground-level concentrations of ozone are expected to occur within the Lower Fraser Valley within the LFV photochemical modelling domain.

- Duration: long-term – emissions of precursors and subsequent changes to ambient ground-level concentrations of ozone are expected to occur for the operational life of the terminals and, therefore, are considered long-term.
- Frequency: continuous – fugitive precursor (VOC) emissions occur continuously during tank operations.
- Reversibility: long-term – fugitive emissions of VOCs which are chemical precursors for secondary pollutants will extend for the operational life of the terminal. All VOC emissions are reversible as the fugitive emissions will cease when the facility is decommissioned.
- Magnitude: medium – the increase in ambient ground-level concentrations of ozone is expected to be small relative to existing concentrations, but for some areas within the LFV might approach Canadian Ambient Air Quality Standards for ozone.
- Probability: high – an increase in Project-related product storage and handling in tanks will result in precursor (VOC) emissions, which will contribute to secondary ozone formation.
- Confidence: moderate – based on a good understanding of cause-effect relationships between the Project, air emissions, and atmospheric reactions; however, there is uncertainty with respect to non-Project emissions, and atmospheric chemical reactions are complex.

Air Quality Indicator – Fugitive Hydrogen Sulphide and Mercaptans

The following provides the evaluation of significance of potential residual effects on the hydrogen sulphide and mercaptans emissions indicator.

Increase in Ambient Ground-level Concentrations of H_2S and Mercaptans

The increase in ambient ground-level concentrations of H_2S and mercaptans is considered to have a negative impact balance because of the associated odour nuisance in cases when the odour detection threshold is exceeded. As shown in Table 7.5.4-6 point 1(b), the increase in ambient ground-level concentrations of H_2S and mercaptans is confined to the Air Quality RSA. Emissions are expected to change ambient H_2S and mercaptans concentrations continuously in the RSA due to the handling and storage of product. As shown in Table 7.5.4-5, the Project-related increases of H_2S and mercaptans concentrations are well below their respective odour detection thresholds. Therefore, the potential residual effect is considered to be of low magnitude. The residual effect will extend for more than 10 years over life of the operating terminal and is, therefore, reversible in the long-term. The probability of this occurring is high, because H_2S and mercaptans emissions will occur and cause increases in ambient ground-level concentrations. The cause-effect relationships are well understood and estimations of H_2S and mercaptans emissions were based on design information for the Project. Therefore, confidence in the residual effects assessment is high. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Air Quality RSA – changes to ambient ground-level concentrations of H_2S and mercaptans are expected to occur within the Air Quality RSA.
- Duration: long-term – emissions of H_2S and mercaptans and subsequent changes to ambient ground-level concentrations are expected to occur for the life of the operating terminal and, therefore, are considered long-term.
- Frequency: continuous – emissions of H_2S and mercaptans will occur continuously throughout the operations phase.
- Reversibility: long-term – emissions of H_2S and mercaptans during operations at the terminals will extend over the life of the operating terminal. Emissions of H_2S and mercaptans cease when the facility is decommissioned.

- Magnitude: low – the increase in ambient ground-level concentrations of H_2S and mercaptans is expected to cause odour nuisance at some locations but is not expected to approach regulatory limits.
- Probability: high – an increase in Project volumes of product being handled and stored will result in an increase in emissions of H_2S and mercaptans.
- Confidence: moderate – based on a good understanding of cause-effect relationships but assumptions were made for equipment based on previous project pending Project design.

7.5.4.7 Summary

As identified in Table 7.5.4-6, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on air emissions indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with the construction and operation of the proposed tanks and associated terminal work on air emissions will not be significant.

7.5.5 Greenhouse Gas Emissions

As discussed in Section 7.2.5.3, during the installation of the proposed tanks and associated terminal work, site preparation, operation of vehicles and equipment, and other construction activities will result in GHG emissions. During operations, the main sources of direct GHG emissions will be regular transportation and equipment use during maintenance activities and normal operations, as well as fugitive emissions from working and standby losses from storage tanks and the fugitive emissions from the corresponding valves and connectors. Electricity consumption at the terminals, mainly by the booster pumps, will result in large amounts of indirect GHG emissions. Tank-related GHG emissions are summarized in Table 7.2.5-4.

The assessment of effects on GHG emissions has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, Westridge Marine Terminal and pipeline reactivation), since GHG emissions associated with the construction and operation of each Project component are aggregated for the Project as a whole and then compared to provincial and federal GHG inventory totals.

The assessment of effects on GHG emissions for the Project as a whole is presented in Section 7.2.5. Table 7.2.5-8 and accompanying discussion in Section 7.2.5.3 provide an evaluation of potential residual effects of tank installation and associated work on GHG indicators.

7.5.6 Acoustic Environment

Sections 7.2.6.1, 7.2.6.2 and 7.4.6 provide the assessment indicators, measurement endpoints, spatial boundaries and acoustic environment context for the assessment of potential effects of the proposed tanks and terminal work on the acoustic environment.

7.5.6.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with proposed tanks and terminal work on the acoustic environment indicators listed in Table 7.5.6-1 were based on the results of desktop analysis, modelling and engagement with Aboriginal communities, landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.5.6-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.6.4.

TABLE 7.5.6-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON THE ACOUSTIC ENVIRONMENT

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Acoustic Environment Indicator – Sound Levels				
1.1 Changes in sound levels during construction	All	LSA	• See recommended mitigation measures outlined in Table 7.4.6-1 Acoustic Environment.	• Increase in sound levels at terminals during construction period.
1.2 Changes in sound levels during operations	All	LSA	• Review and analyze equipment specifications to ensure sound emissions from mechanical equipment are equal to or less than the sound emissions used in the Terrestrial Noise and Vibration Technical Report. • See recommended mitigation measures outlined in Table 7.4.6-1 Acoustic Environment.	• Increase in continuous sound levels from operations of new equipment at terminals.

Notes: 1 LSA = Acoustic Environment LSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.5.6.2 Residual Effects

The potential residual environmental effects on the acoustic environment indicators associated with proposed tanks and terminal work (Table 7.5.6-1) are:

- increases in sound levels at terminals during construction period; and
- Increase in continuous sound levels from operation of new equipment at terminals.

7.5.6.3 Significance of Residual Effects

Table 7.5.6-2 provides a summary of the significance evaluation of the potential residual environmental effects on the acoustic environment indicator resulting from proposed tanks and terminal work.

A quantitative assessment of the acoustic environment was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects for proposed tanks and terminal work. The evaluation of significance of each of the potential residual effects for the acoustic environment relies primarily on the magnitude, duration and extent of the potential change. The definitions for these elements are provided in Table 7.1-2. However, magnitude of residual effects requires further definition for the acoustic environment evaluation and is indicator specific. Magnitude for sound levels was defined in Section 7.4.6.3 based on a combination of the degree of compliance with provincial guidelines or legislation and the amount of change in the existing conditions that may be experienced.

TABLE 7.5.6-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON THE ACOUSTIC ENVIRONMENT

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Acoustic Environment Indicator – Sound Levels									
1(a) Increase in sound levels during construction period.	Negative	LSA	Short-term	Isolated	Short-term	Low to medium	High	Moderate	Not Significant
1(b) Increase in continuous sound levels from operations of new tanks.	Negative	LSA	Long-term	Continuous	Long-term	Negligible to medium	High	Moderate	Not Significant
1(c) Combined effects on the sound levels indicator (1[a] and 1[b]).	Negative	LSA	Long-term	Continuous	Long-term	Negligible to medium	High	Moderate	Not Significant

Notes: 1 LSA = Acoustic Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Acoustic Environment Indicator – Sound Levels

Increase in Sound Levels During Construction Period

The potential for the increase in daytime or nighttime sound levels for human receptors associated with construction of proposed tanks and associated terminal work is considered to have a negative impact balance. Based on the results of the analysis in the Terrestrial Noise and Vibration Technical Report of Volume 5C, the spatial extent of changes to sound levels from construction at Edmonton, Sumas and Burnaby terminals were limited to within the Acoustic Environment RSA. However, the significance of changes is based on the compliance with regulatory guidance for noise. Compliance with regulatory requirements occurs within the Acoustic Environment LSA. The duration of the sounds experienced at receptors is dependent on the activity; each type of sound will last only for the particular phase of construction (*e.g.,* earthworks, tank construction, foundations).

The frequency of sound emissions during each construction activity will be isolated since construction is cyclic and involves use of mobile equipment and intermittent use of tools. All sound level changes are immediately reversible. As soon as construction activity stops, the sound level changes are reversed.

The results of predictive modelling for construction of new equipment at the terminal indicates the magnitude of changes in sound levels that will be experienced by people living within 1.5 km of a terminal. Noise controls that will be in use during the construction phase, particularly the use of silencers on mobile equipment and the implementation of a Noise Management Plan are expected to control the amount of sound to within acceptable levels as established in the Terrestrial Noise and Vibration Technical Report. Controlling the magnitude of sound levels also limits the spatial extent of the potential change.

The only variation in residual affects is the magnitude of potential effects. The definition for magnitude follows the construction descriptors found in Section 7.4.6.3. This varies depending on the distance between the construction activities and the surrounding receptors. As such, Table 7.5.6-3 presents a summary of the relevant parameters and resulting predicted magnitude.

TABLE 7.5.6-3

SUMMARY OF SOUND LEVEL MAGNITUDE FOR APPLICABLE TERMINAL CONSTRUCTION

Terminal Facility	Distance to Closest Receptor (m)	Predicted Sound Level (Leq in dBA)	Criteria		Magnitude
			BC OGC/AER Daytime PSL (dBA)	Health Canada Guidance (dBA)	
Edmonton, AB	No receptor within the Acoustic Environment LSA. Closest receptor is 1.9 km.	< 56	60	75	Low
Sumas, BC	60	85	60	75	High[1]
Burnaby, BC	50	86	66	75	High[1]

Note: 1 Without additional mitigation. A noise management plan focussed on urban construction is expected to manage these noise levels to a medium magnitude.

While the prediction results indicate there is potential for high magnitude effects at receptors due to construction noise, the predictions represent a snapshot of the highest expected activity. Normal construction sounds will vary throughout the day, and can be controlled through detailed planning and use of sound reduced equipment in densely populated areas. The detailed construction planning required to fully assess urban sound levels is not available at this stage of project planning. A detailed noise management plan to be prepared for use during construction in urban environments is expected to bring potential sound levels to within medium magnitude levels. A summary of the rationale for all of the significance criteria is provided below (Table 7.5.6-2, point 1[a]).

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER *Directive 038* (ERCB 2007) and BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) are achieved within the Acoustic Environment LSA.
- Duration: short-term – the events causing changes in sound levels will occur only during the construction phase.
- Frequency: isolated – the events causing changes in sound levels will occur at residential dwellings during the construction phase
- Reversibility: short-term – the period over which the change in sound levels extends is the construction period. However, sound level changes will cease when construction activities have finished.
- Magnitude: low to medium – at the Edmonton Terminal, low magnitude effects are predicted; however, for Burnaby and Sumas terminals, high magnitude noise predictions can be mitigated to a medium effect by ensuring detailed noise management in urban areas.
- Probability: high – based on the proximity of residences to the terminals.
- Confidence: moderate – based on the nature of data inputs.

Increase in Continuous Sound Levels From Operations of Equipment

Noise from tank terminal operations will be continuous sound from pumping and support equipment located on these sites. Since these are expansions of existing terminals, sounds would be similar to those already generated on these sites.

The spatial extent of the sound would be limited to the Acoustic Environment LSA. The duration of the tank terminal sounds is long-term, throughout the life of the pipeline. The effect of an increase in sound levels during operations will extend for the life of the terminals and, consequently, is of long-term reversibility. However, the effect is reversible since the increase in sound levels cease as soon as the sound stops, which would be at tank decommissioning.

The only variation in residual affects is the magnitude of potential effects. The definition for magnitude follows the operation descriptors found in Section 7.4.6.3. This varies depending on the distance between the terminal and the surrounding receptors. As such, Table 7.5.6-4 presents a summary of the relevant parameters and resulting predicted magnitude.

TABLE 7.5.6-4

SUMMARY OF SOUND LEVEL MAGNITUDE FOR APPLICABLE TERMINAL OPERATION

Terminal Facility	Distance to Closest Receptor (m)	Predicted Sound Level (L_{eq} in dBA/%HA)	Criteria		Magnitude
			BC OGC/AER Nighttime PSL (dBA)	Health Canada Guidance (% HA)	
Edmonton, AB	No receptor within Acoustic Environment LSA. Compliance is demonstrated at Acoustic Environment LSA limit of 1.5 km.	36/1.2	40	6.5	Low
Sumas, BC	60	35/1.2	40	6.5	Negligible
Burnaby, BC	50	46/3.5	46	6.5	Medium

A summary of the rationale for all of the significance criteria is provided below (Table 7.5.6-2, point 1[b]).

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER *Directive 038* (ERCB 2007) and BC OGC *Noise Control Best Practices Guideline* (BC OGC 2009) are achieved within the Acoustic Environment LSA.
- Duration: long-term – the event causing the increase in sound levels is the operation of the proposed tanks which occurs over the operational life of the terminals.
- Frequency: continuous – the event causing the increase in sound levels is the operation of the tanks which occurs continually over the assessment period.
- Reversibility: long-term – the increase in sound levels during operations at the terminals will extend over the operational life of the terminals. All sound level changes are reversible as the sound will cease when the facility is decommissioned.
- Magnitude: negligible to medium – with the implementation of appropriate mitigation measures, sound levels at receptors are expected to comply with AER, and BC OGC *Noise Control Best Practices Guideline* and Health Canada guidance.
- Probability: high – the new equipment are mechanical sources of sound and will increase sound levels for nearby receptors during operations.
- Confidence: moderate – the assessment is based on a combination of measured existing data, theoretical formulae and current Project design.

Combined Effects on Sound Levels

The evaluation of the combined effects of proposed tanks and associated terminal work on the acoustic environment considers collectively the assessment of the likely potential residual effects on the sound levels indicator. The residual effects for the sound levels indicator do not combine to result in new ratings for the various components since the occurrences of sound happen at different times during the Project Therefore, the combined effects represents the worst-case or most negative effect for each evaluation criteria between the two residual effects (Table 7.5.6-2, point 1[c]). Effectively, this is the effects from terminal operations, as terminal construction is of short-term duration and reversibility.

A summary of the rationale for all of the significance criteria of combined effects on sound levels is provided below.

- Spatial Boundary: Acoustic Environment LSA – compliance with the AER Directive 038 and BC OGC *Noise Control Best Practices Guideline* are achieved within the Acoustic Environment LSA.
- Duration: long-term – the event causing the combined effects on sound levels reflects the operations of the terminal which occurs over the operational life of the terminals.
- Frequency: continuous – the event causing the combined effects on sound levels reflects the operations of the terminal which occurs continually over the assessment period.
- Reversibility: long-term – the combined effects on sound levels reflect operations at terminal which will extend over the operational life of the terminals. All sound level changes are reversible as the sound will cease when the pipeline is decommissioned.
- Magnitude: negligible to low – with the implementation of appropriate mitigation measures, sound levels at receptors are expected to comply with AER, and BC OGC *Noise Control Best Practices Guideline* and Health Canada guidance.
- Probability: high – the new equipment are mechanical sources of sound and will increase sound levels for nearby receptors during operation.
- Confidence: moderate - the assessment is based on a combination of measured existing data, theoretical formulae and current Project design.

7.5.6.4 Summary

As identified in Table 7.5.6-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect of high magnitude on the acoustic environment indicators that cannot be technically or economically mitigated. Consequently, it is concluded that the residual effects arising from the construction and operations of the proposed tanks and associated terminal work on the acoustic environment will be not significant.

7.5.7 Fish and Fish Habitat

Hydrostatic testing is planned for the piping and new tanks to be installed within the Edmonton, Sumas and Burnaby terminals. The Edmonton Terminal is located in the Lower North Saskatchewan River Watershed, which is known to contain three Alberta indicator species (*i.e.,* burbot, northern pike and walleye). The Sumas Terminal is located in the Chilliwack River Watershed, which contains all five BC indicator species. The Burnaby Terminal is located in the Lower Fraser River Watershed, which is known to contain all five BC indicator species (*i.e.,* bull trout/Dolly Varden, Chinook salmon, coho salmon, cutthroat trout and rainbow trout/steelhead). In addition, the headwaters of Eagle Creek are located within 30 m of the proposed Footprint for the Burnaby Terminal. At the time of writing, the locations of source water for hydrostatic testing had not been confirmed. Test water may be diverted from a nearby river or creek, or purchased from municipalities depending on availability from natural sources. If hydrostatic test water is obtained from a river or creek this will cause an interaction with fish and fish habitat indicators, specifically riparian habitat, instream habitat and the indicator species found in the watershed from which test water is withdrawn.

The assessment of effects on fish and fish habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks and pipeline reactivation), since the components will have similar effect pathways (*i.e.,* riparian habitat, instream habitat and fish mortality and injury) on fish indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for fish indicators.

The assessment of effects on fish and fish habitat for the Project as a whole is presented in Section 7.2.7. Table 7.2.7-3 and accompanying discussion in Section 7.2.7.6 provide an evaluation of potential residual effects of proposed tanks and terminal work on fish indicators.

7.5.8 Vegetation

Sections 7.2.9.1 and 7.2.9.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of proposed tanks and terminal work on vegetation.

7.5.8.1 Ecological Context

Activities that require clearing of previously undisturbed lands have the potential to affect native vegetation. Project activities at the Edmonton Terminal and the Burnaby Terminal will not involve clearing of previously undisturbed lands and, therefore, are not expected to have an effect on native vegetation. Project activities at the Sumas Terminal will require clearing of undisturbed lands and, therefore, have the potential to affect native vegetation. The introduction and spread of weeds has the potential to occur during any anthropogenic disturbance.

Section 7.2.9.3 provides additional details on the ecological context for vegetation.

7.5.8.2 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with the construction and operations of the proposed tanks and terminal work on vegetation indicators are listed in Table 7.5.8-1. These interactions are based on the results of the literature review, desktop analysis, engagement with Aboriginal communities, regulatory authorities, stakeholders and the general public (Section 3.0) and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.5.8-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.9.4.

TABLE 7.5.8-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON VEGETATION

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Vegetation Indicator – Vegetation Communities of Concern				
1.1 Loss or alteration of native vegetation	Sumas	Footprint	• See recommended mitigation measures outlined in Table 7.4.9-1 Vegetation.	• Loss or alteration of the composition of 0.7 ha of native vegetation.
1.2 Loss or alteration of rare ecological communities	Sumas	LSA	• See recommended mitigation measures outlined in Table 7.4.9-1 Vegetation.	• Some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare ecological communities are located adjacent to the tanks and terminal work they may be indirectly affected by changes in hydrology or light levels.
2. Vegetation Indicator – Plant and Lichen Species of Concern				
2.1 Loss or alteration of rare plant occurrences	Sumas	LSA	• See recommended mitigation measures outlined in Table 7.4.9-1 Vegetation.	• Some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare plant sub-populations are located adjacent to the tanks and terminal work they may be affected by changes in dust, hydrology or light levels.
2.2 Loss or alteration of rare lichen occurrences	Sumas	LSA	• See recommended mitigation measures outlined in Table 7.4.9-1 Vegetation.	• Some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare lichen sub-populations are located adjacent to the tanks and terminal work they may be affected by changes in dust, hydrology or light levels.

TABLE 7.5.8-1 Cont'd

Potential Effect	Terminal	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern				
3.1 Weed introduction and spread	All	RSA	• See recommended mitigation measures outlined in Table 7.4.9-1 Vegetation.	• Weed introduction and spread.

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.
2 Detailed mitigation measures are outlined in the Facilities EPP (Volume 6C).

7.5.8.3 Potential Residual Effects

The potential residual environmental effects on vegetation indicators associated with Project activities associated with the construction and operations of the proposed tanks and terminal work (Table 7.5.8-1) are:

- alteration of the composition of 0.7 ha of native vegetation;
- some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare ecological communities are located adjacent to the proposed tanks and terminal work they may be indirectly affected by changes in hydrology or light levels;
- some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare plant sub-populations are located adjacent to the proposed tanks and terminal work they may be affected by changes in dust, hydrology or light levels;
- some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare lichen sub-populations are located adjacent to the proposed tanks and terminal work they may be affected by changes in dust, hydrology or light levels; and
- weed introduction and spread.

7.5.8.4 Significance Evaluation of Potential Residual Effects

Table 7.5.8-2 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations of proposed tanks and terminal work on vegetation. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.5.8-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF PROPOSED TANKS AND ASSOCIATED TERMINAL WORK ON VEGETATION

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Vegetation Indicator – Vegetation Communities of Concern									
1(a)	Loss or alteration of the composition of 0.7 ha of native vegetation.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Low to medium	High	High	Not significant
1(b)	Some disturbance or alteration of a rare ecological community, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Medium	Low	High	Not significant
1(c)	If rare ecological communities are located adjacent to the proposed tanks and terminal work they may be indirectly affected by changes in dust, hydrology or light levels.	Negative	LSA	Short-term	Isolated	Medium to long-term	Low	Low	Moderate	Not significant
2.	Vegetation Indicator – Plant and Lichen Species of Concern									
2(a)	Some disturbance or alteration of a rare plant occurrence, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Medium	High	High	Not significant
2(b)	Some disturbance or alteration of a rare lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Medium	Low	High	Not significant
2(c)	If rare plant and lichen sub-populations are located adjacent to the proposed tanks and terminal work they may be affected by changes in dust, hydrology or light levels.	Negative	LSA	Short-term	Isolated	Short to long-term	Low	Low	High	Not significant
3.	Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-native Species Identified as a Concern									
3(a)	Weed introduction and spread.	Negative	RSA	Short-term	Isolated	Short to medium-term	Low to medium	High	High	Not significant

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the vegetation communities of concern indicator and the rare plant and lichen species of concern indicator was determined to be the same for the construction and operations of proposed tanks and terminal work as for pump station construction and operations (Table 7.5.8-2, points 1[a] to 1[c], 2[a] to 2[c]). Table 7.4.9-2 and the accompanying discussion in Section 7.4.9.4 provide an evaluation of potential residual effects of Project activities at pump station facilities and their significance on the applicable vegetation indicator. The exceptions are in Table 7.5.8-2, points 1[b] and 1[c] where probability is low due to the unlikely occurrence of rare ecological communities within the footprint and LSA of the Project activities and point 2[c] where the probability is low because of the limited amount of native vegetation being cleared (0.7 ha) and the surrounding disturbance makes for low potential rare plant habitat. In addition, the significance evaluation of the potential residual effect on the presence of infestations of provincial weed species and other invasive non-native species identified as a concern indicator was determined to be the same for the construction and operations of proposed tanks and terminal work as for pipeline construction and operations (Table 7.5.8-2, point 3[a]). Table 7.2.9-3 and the accompanying discussion in Section 7.2.9.6 provide an evaluation of potential residual effects of Project activities and their significance on this vegetation indicator.

7.5.8.5 Summary

As identified in Table 7.5.8-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on vegetation indicators of high magnitude that cannot be technically or economically mitigated. Consequently, is it concluded that the residual environmental effects arising from the construction and operations of the proposed tanks and associated terminal work on vegetation will be not significant.

7.5.9 Wildlife and Wildlife Habitat

Activities that require clearing of previously undisturbed lands have the potential to affect wildlife and wildlife habitat. Project activities at the Edmonton Terminal will not involve clearing of previously undisturbed lands and, therefore, are not expected to have a notable effect on wildlife and wildlife habitat. Project activities at the Burnaby Terminal will require clearing of some remnant treed patches within the existing fenceline. Given that these patches are small, fragmented and surrounded by highly disturbed areas, the habitat value within the existing fenceline in the Burnaby Terminal is considered to be low and, therefore, Project activities at the Burnaby Terminal are also not expected to have a notable effect on wildlife and wildlife habitat. Project activities at the Sumas Terminal will require clearing of undisturbed forested habitat that is contiguous with adjacent forests and, therefore, have the potential to affect wildlife and wildlife habitat.

The assessment of effects on wildlife and wildlife habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, other ancillary facilities, and the Westridge Marine Terminal), since the components will have similar effect pathways (*i.e.,* change in habitat movement and mortality risk) on wildlife indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for wildlife indicators. Since the activities at the Edmonton and Burnaby terminals are not expected to have a notable impact on wildlife indicators, the Edmonton and Burnaby terminals were not carried through the effects assessment. Wildlife indicators that may be affected by proposed tanks and terminal work at the Sumas Terminal include coastal riparian small mammals, bats, mature/old forest birds, early seral forest birds, riparian and wetland birds, rusty blackbird, western screech-owl, great blue heron, bald eagle, common nighthawk, northern goshawk, olive-sided flycatcher, pond-dwelling amphibians, and stream dwelling amphibians.

The assessment of effects on wildlife and wildlife habitat for the Project as a whole is presented in Section 7.2.10. Table 7.2.10-6 and accompanying discussion in Section 7.2.10.9 provide the evaluation of potential residual effects of proposed tank and terminal work on mammal indicators, Table 7.2.10-9 and accompanying discussion in Section 7.2.10.10 provide the evaluation of potential residual effects of proposed tank and terminal work on bird indicators, Table 7.2.10-12 and accompanying discussion in Section 7.2.10.11 provide the evaluation of potential residual effects of proposed tank and terminal work on amphibian indicators, and Table 7.2.10-15 and accompanying discussion in Section 7.2.10.12 provide the evaluation of potential residual effects of proposed tank and terminal work on the reptile indicator. No significant adverse effect on the wildlife indicators has been identified as a result of the Project.

7.5.10 Species at Risk

The construction and operations of proposed tanks and the associated terminal may affect fish, vegetation and wildlife species at risk. Section 7.2.11 provides a discussion of the fish and wildlife species used as indicators for species at risk. Vegetation species at risk are considered under the plant and lichen species of concern indicator. Although not all species at risk are discussed explicitly under each indicator, potential Project effects were assessed in consideration of all species at risk. The indicators used to represent fish and fish habitat, vegetation and wildlife and wildlife habitat were carefully selected to ensure that the full range of potential Project effects on species at risk was addressed and mitigation measures to reduce these effects will apply to all species at risk, not just the indicators. Section 7.2.7 Fish and Fish Habitat, Section 7.2.9 Vegetation and Section 7.2.10 Wildlife and Wildlife Habitat provide the significance rationale for applicable indicator species. No significant adverse effects on species at risk have been identified as a result of the pipeline and facilities component of the Project.

7.6 Effects Assessment – Westridge Marine Terminal Expansion and Operations

Using the assessment methodology described in Section 7.1, the following subsections evaluate the potential environmental effects associated with the construction and operations of the Westridge Marine Terminal component of the Project. Environmental elements potentially interacting with construction and operations of the Westridge Marine Terminal are identified in Table 7.6-1.

TABLE 7.6-1

ELEMENT INTERACTION WITH THE PROPOSED WESTRIDGE MARINE TERMINAL COMPONENT

Element	Interaction with Westridge Marine Terminal Component	
	Construction	Operations[1]
Physical and Meteorological Environment	Yes	Yes
Soil and Soil Productivity	Yes	Yes
Water Quality and Quantity	Yes	Yes
Air Emissions	Yes	Yes
GHG Emissions	Yes	Yes
Acoustic Environment	Yes	Yes
Fish and Fish Habitat (freshwater)	No – freshwater fish and fish habitat will not be affected by construction of the Westridge Marine Terminal	No – freshwater fish and fish habitat will not be affected by operations of the Westridge Marine Terminal
Wetlands	No – wetlands will not be affected by construction of the Westridge Marine Terminal	No – wetlands will not be affected by operations of the Westridge Marine Terminal
Vegetation	Yes	Yes
Marine Sediment and Water Quality	Yes	Yes
Marine Fish and Fish Habitat	Yes	Yes
Wildlife and Wildlife Habitat	Yes	Yes
Marine Mammals	Yes	No – marine mammals will not be affected by operations of the Westridge Marine Terminal
Marine Birds	Yes	Yes
Species at Risk	Yes	Yes

Note: 1 Activities during operations include loading and unloading operations, vegetation management, storage of jet fuel and spill response capabilities.

The potential environmental effects associated with the Westridge Marine Terminal, as well as the accompanying proposed mitigation measures and resulting residual effects are presented in the following subsections for each environmental element. In addition, the evaluation of significance using the criteria presented in Table 7.1-2 for the residual effects associated with the applicable environmental elements is also provided.

7.6.1 Physical Environment and Meteorlogical Environment

Sections 7.2.1.1 and 7.2.1.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of construction and operations of the Westridge Marine Terminal on the physical environment.

7.6.1.1 Physical Environment Context

Grading and foreshore expansion will be required at the Westridge Marine Terminal to accommodate equipment and infrastructure associated with dock construction and operations.

7.6.1.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the construction and operations activities at the Westridge Marine Terminal were based on the results of the literature review and desktop analysis, and the professional experience of the assessment team. No interactions between construction and operations activities at the

Westridge Marine Terminal and some of the physical environment indicators were predicted and, consequently, no potential effects were identified for the following indicators: terrain instability at watercourses; alteration of topography from blasting; and acid generation or metal leaching.

A summary of mitigation measures, provided in Table 7.6.1-1, was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.1.4.

TABLE 7.6.1-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON PHYSICAL ENVIRONMENT

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Physical Environment Indicator – Terrain Instability			
1.1 Terrain and seabed instability	LSA	• Use hand clearing methods where directed by the Inspector to avoid or reduce disturbance to the ground surface on sensitive terrain [Section 8.1]. • Grade the work site to the specifications of the geotechnical or civil engineer [Section 8.1]. • Ensure graded material does not spread off-site [Section 8.1]. • Place rock armouring progressively, where required, to minimize erosion and prevent the loss of infill material [see Infilling – Rock Armouring Drawing in Appendix Q] [Section 8.2].	• No residual effect identified.
2. Physical Environment Indicator – Topography			
2.1 Alteration of topography and bathymetry	LSA	• Ensure all conditions outlined in authorizations, approvals and/or permits are met during marine infilling [Section 8.2]. • Review and abide by all specifications for infilling activities as defined in the Trans Mountain's Infill Design (Volume 4A) and as directed by a qualified engineer [Section 8.2]. • See additional recommended mitigation measures provided for potential effect 1.1 of this table.	• Alteration of topography and bathymetry along the shoreline where foreshore expansion is required.

Notes: 1 LSA = Physical Environment LSA.

2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.1.3 Potential Residual Effects

The potential residual environmental effect on physical environment indicators associated with construction and operations activities at Westridge Marine Terminal is alteration of topography and bathymetry along the shoreline where foreshore expansion is required (Table 7.6.1-1).

Potential terrain and seabed instability resulting from construction and operations activities at Westridge Marine Terminal is concluded not to have a residual effect because instability potential is predicted to be eliminated through the implementation of mitigation measures (Table 7.6.1-1).

7.6.1.4 Significance Evaluation of Potential Residual Effects

Table 7.6.1-2 provides a summary of the significance evaluation of the potential residual environmental effects on physical environment indicators resulting from construction and operations activities at Westridge Marine Terminal. The rationale used to evaluate the significance of the residual environmental effect is provided below.

TABLE 7.6.1-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON PHYSICAL ENVIRONMENT

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Physical Environment Indicator – Topography									
1(a)	Alteration of topography along the shoreline where foreshore expansion is required.	Negative	Footprint	Short-term	Isolated	Permanent	Low	High	High	Not significant

Notes: 1 LSA = Physical Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of alteration of topography at the Westridge Marine Terminal (Table 7.6.1-2, point 1[a]) was determined to be the same for the construction and operations activities at the Westridge Marine Terminal as for the construction and operations of the proposed pump stations. Table 7.4.1-2 and the accompanying discussion in Section 7.5.1.4 provide an evaluation of this potential residual effect at the Westridge Marine Terminal and its significance on the applicable physical environment indicator.

7.6.1.5 Summary

As identified in Table 7.6.1-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on physical environment indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with construction and operations activities at the Westridge Marine Terminal on the physical environment will be not significant.

7.6.2 Soil and Soil Productivity

Sections 7.2.2.1 and 7.2.2.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of construction and operations of the Westridge Marine Terminal on soil and soil productivity.

7.6.2.1 Soil Context

Activities at the Westridge Marine Terminal will be conducted on previously disturbed lands owned by Trans Mountain. Refer to Section 7.2.2.3 for additional soil context.

7.6.2.2 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with the construction and operations activities at the Westridge Marine Terminal on the soil and soil productivity indicators are listed in Table 7.6.2-1. These interactions were based on the results of the literature review, desktop analysis, and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.6.2-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.2.4.

TABLE 7.6.2-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON SOIL AND SOIL PRODUCTIVITY

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Soil Indicator – Soil Productivity			
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging	Footprint	• Salvage topsoil from locations in the Westridge Marine Terminal site where grading and/or padding is necessary [Section 8.1]. • Locate topsoil piles outside of the construction area where topsoil will be replaced following earthworks. Locate topsoil storage piles on the upslope side of the site to avoid contamination from accidental spills and away from natural drainage patterns [Section 8.1]. • Salvage all available topsoil (min. 15-20 cm or 50% organic material and 50% mineral soil), unless the material is unsuitable (*e.g.,* bedrock, gravel, rock) using the Environmental Facility Drawings of Westridge Marine Terminal as a guide [Section 8.1]. • Keep subsoil piles separate from topsoil/root zone material piles. Maintain a minimum separation distance of 1 m between topsoil/root zone material and subsoil piles [Section 8.1].	• Mixing of topsoil/root zone material and subsoil.
1.2. Decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land	LSA	• Follow all measures outlined in the Water Discharge Procedures Management Plan and in the Water Discharge Form (see Appendix C) related to dewatering [Section 8.3]. • Monitor discharge locations to ensure that no erosion, flooding or icing occurs. If conditions become saturated to the extent that adequate natural filtration is no longer occurring, suspend dewatering and move the discharge to another approved location (confirm that appropriate approvals and, if warranted, soil testing have been completed) or construct a holding pond for the water and release the water when natural filtration is feasible [Section 8.3]. • Ensure the areas that are to receive discharged water are approved by the Lead Activity Inspector and the Inspector in accordance with the applicable regulatory guidance [Section 8.3]. • Dewater onto approved areas where water will be filtered through vegetation and soils before returning to a waterbody. Provide scour protection (*e.g.,* use of rock aprons, plastic sheeting, plywood, straw bales) or an energy diffuser (*e.g.,* cone with baffles, frog's foot) at the discharge site as directed by the Inspector. The rate of discharge will be reduced if these measures are ineffective [Section 8.3]. • See additional erosion control measures in Section 8.1 of the Westridge Marine Terminal EPP.	• No residual effect identified.
2. Soil Indicator – Soil Degradation			
2.1 Degradation of soil structure due to compaction and rutting	Footprint	• Adhere to the measures outlined in the Wet Soils Contingency Plan (see Appendix B) during earthworks on non-gravel padded areas during wet soil conditions [Section 8.1]. • Postpone construction, suspend equipment travel or utilize construction alternatives in the event of wet soils located outside of the development zone in order to reduce terrain disturbance and soil structure damage or areas within the development zone prior to gravel padding to prevent excessive sediment production [Section 8.1]. • The wet soil conditions shut-down decision will be made by the Construction Manager in consultation with the Lead Activity Inspector and the Inspector [Section 8.1]. • Ensure that there is low enough soil moisture to allow construction without causing excessive rutting or soil compaction [Section 8.1]. • See additional compaction and rutting mitigation measures in Section 8.1 of the Westridge Marine Terminal EPP.	• Degradation of soil structure and impairment of rooting zone due to compaction and rutting.
2.2 Loss of topsoil/root zone material through wind and water erosion	Footprint	• Trans Mountain will implement a monitoring program to determine the effectiveness of the erosion and sediment control mitigation measures during construction in preventing terrestrial sediment loading into the marine environment [Section 7.0]. • Maintain existing surface drainage across the Westridge Marine Terminal [Section 8.1]. • Implement the Soil Erosion and Sediment Control Contingency Plan, if necessary (see Appendix B) [Section 8.1].	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.

TABLE 7.6.2-1 Cont'd

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.2 Loss of topsoil/root zone material through wind and water erosion (cont'd)	Footprint	• Install temporary erosion and sediment control measures in areas of exposed soils or soil piles (see Drawing [Sediment Fence] provided in Appendix F) [Section 8.1]. • Install erosion and sediment control structures and materials (*e.g.,* sediment fencing) and implement as warranted, erosion control measures outlined in the Soil Erosion and Sediment Control Contingency Plan (see Appendix B), as soon as practical following a heavy rain event, to ensure that sediments in water flowing from the Westridge Marine Terminal do not adversely affect the marine environment and the surrounding terrain [Section 8.1]. • All surface water runoff generated during construction will be redirected and stored in a settling pond or will be suitably filtered. Surface water runoff will be tested and treated, if necessary, and discharged into vegetated areas or into the marine environment, where practical [Section 8.1]. • Monitor topsoil piles during the growing season for wind and water erosion, and weed growth until the soils are replaced or stored in berms. Implement remedial measures to control erosion (see Soil Erosion and Sediment Control Contingency Plan in Appendix B) and weed growth (see Weed and Vegetation Management Plan in Appendix C), when warranted [Section 8.1]. • Postpone replacement during wet conditions or high winds to prevent damage to soil structure or erosion of topsoil/root zone material [Section 8.4]. • Establish long-term topsoil/root zone material storage berms at locations away from regular Westridge Marine Terminal operational activity and areas with potential for overland water flow and storage berm erosion [Section 8.4]. • See additional erosion control measures in Section 8.1 and 8.4 of the Westridge Marine Terminal EPP.	• See above.
2.3 Degradation of soil structure due to pulverization of soil and sod	Footprint	• Apply water or approved tackifier to disturbed areas if traffic and wind conditions result in excessive dust. The frequency of dust abatement measures will be increased during periods of high wind [Section 8.1]. • Control dust emissions by applying dust suppressants, if warranted. Ensure the Inspector approves the dust suppressants prior to use [Section 8.1]. • Additional dust abatement measures (*e.g.,* covering topsoil piles, installing wind fences, applying tackifier) will be implemented, when warranted, during topsoil/root zone salvage and construction activities [Section 8.1].	• Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.
2.4 Erosion of soil as a result of release of hydrostatic test water on land	LSA	• See recommended mitigation measures outlined in potential effect 1.2 of this table.	• No residual effect identified.
3. Soil Indicator – Soil Contamination			
3.1 Disturbance of previously contaminated soil	Footprint	• Implement the Contamination Discovery Contingency Plan (see Appendix B) and applicable measures from the Waste Management Standard (see Appendix C) in the event contaminated soils are encountered during soil handling procedures [Section 8.1].	• No residual effect identified.
3.2 Contamination of soil as a result of hydrostatic test water on land	LSA	• Ensure that the appropriate testing and treatment measures are implemented in accordance with Sections 7(2) and 7(3) of the *BC Oil and Gas Waste Regulation* [Section 8.3].	• No residual effect identified.

TABLE 7.6.2-1 Cont'd

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3.3 Soil contamination due to spot spills during construction	Footprint	• Maintain all appropriate spill response equipment at all work sites. Assess the risk of resource-specific spills to determine the appropriate type and quantity of spill response equipment and materials to be stored on-site and a suitable location for storage (see Emergency Response Plan in Volume 4B) [Section 7.0]. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are released into the ground or the marine environment. In the event of a spill onshore that does not have the potential to migrate into the marine environment, implement the Marine Spill Contingency Plan (see Appendix B). In the event of a spill in the marine environment, or onshore with the potential to migrate into the marine environment, implement the Marine Spill Contingency Plan (see Appendix B) [Section 7.0]. • Place an impervious tarp or drip tray underneath equipment/vehicles while servicing equipment/vehicles when there exists the potential for accidental spills (*e.g.,* oil changes, servicing of hydraulic systems) [Section 7.0]. • See additional spill prevention and clean-up measures in Section 7.0 of the Westridge Marine Terminal EPP.	• No residual effect identified.

Notes: 1 LSA = Soil LSA.

2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.2.3 Potential Residual Effects

The potential residual environmental effects on the soil and soil productivity indicators associated with the construction and operations activities at the Westridge Marine Terminal (Table 7.6.2-1) are:

- mixing of topsoil/root zone material and subsoil;
- degradation of soil structure and impairment of rooting zone due to compaction and rutting;
- surface erosion of topsoil/root zone material can be expected until a vegetative cover is established; and
- pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.

Some of the potential effects on soil and soil productivity associated with the construction and operations of the Westridge Marine Terminal are predicted to be eliminated through the implementation of mitigation measures (Table 7.6.2-1). The potential effects determined not to have a residual effect are:

- decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land;
- erosion of soil as a result of release of hydrostatic test water on land;
- disturbance of previously contaminated soil;
- contamination of soil as a result of hydrostatic test water on land; and
- soil contamination due to spot spills during construction.

7.6.2.4 Significance Evaluation of Potential Residual Effects

Table 7.6.2-2 provides a summary of the significance evaluation of the potential residual environmental effects of construction and operations activities at the Westridge Marine Terminal on soil and soil productivity.

TABLE 7.6.2-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON SOIL AND SOIL PRODUCTIVITY

Potential Residual Effects	Impact Balance	Spatial Boundary	Temporal Context			Magnitude	Probability	Confidence	Significance[1]
			Duration	Frequency	Reversibility				
1. Soil Indicator – Soil Productivity									
1(a) Mixing of topsoil/root zone material and subsoil.	Negative	Footprint	Short-term	Isolated	Long-term	Low	High	High	Not significant
2. Soil Indicator – Soil Degradation									
2(a) Degradation of soil structure and impairment of rooting zone due to compaction and rutting.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant
2(b) Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.	Negative	Footprint	Short-term	Isolated	Medium-term	Low	High	High	Not significant
2(c) Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	Low to high	High	Not significant
2(d) Combined effects on the soil degradation indicator (2[a] to 2[c]).	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant

Note: 1 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the soil productivity indicator and soil degradation indicator (Table 7.6.2-2, points 1[a], 2[a] to 2[d]) was determined to generally be the same for the construction and operations of the Westridge Marine Terminal as for pipeline construction and operations. The exception is the reversibility of mixing of topsoil/root zone material and subsoil (point 1[a]), which is considered long-term where topsoil is stored in berms (similar to pump stations as noted in Table 7.4.2-2). Table 7.2.2-3 and the accompanying discussion in Section 7.2.2.6 provide an evaluation of potential residual effects of construction and operations of the Westridge Marine Terminal and their significance on the applicable soil and soil productivity indicator.

7.6.2.5 Summary

As identified in Table 7.6.2-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the soil and soil productivity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operations activities at the Westridge Marine Terminal on soil and soil productivity will be not significant.

7.6.3 Water Quality and Quantity

Sections 7.2.3.1 and 7.2.3.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of the construction and operations of the Westridge Marine Terminal on water quality and quantity.

7.6.3.1 Water Quality and Quantity Context

There are no watercourses or freshwater waterbodies within 30 m of construction or operations activities at the Westridge Marine Terminal. Effects on marine sediment and water quality are discussed in Section 7.6.8.

There are no water supply wells, nor mapped aquifers within the Footprint of the Westridge Marine Terminal, although it is expected, with the proximity to the waters of Burrard Inlet that the groundwater is shallow. No water level data are available. It is likely that groundwater flow is directed to the north toward the inlet.

7.6.3.2 Potential Effects and Mitigation Measures

Effects Considerations

Potential contamination from stormwater discharge during operations of the Westridge Marine Terminal was scoped out of the effects assessment for surface water quality because stormwater, once treated, will be discharged into Burrard Inlet and, therefore, is assessed under the marine sediment and water quality element (Section 7.6.8). Furthermore, since no watercourses or freshwater waterbodies are located within 30 m of construction or operations activities at the Westridge Marine Terminal, reduction of surface water quality due to a spill during construction or operations or from suspended sediment entering the water column were also scoped out of the effects assessment. Small spills during construction or operations have the potential to enter Burrard Inlet and, therefore, this potential effect is assessed under the marine sediment and water quality element (Section 7.6.8).

Identified Potential Effects

Potential effects associated with the construction and operations activities at the Westridge Marine Terminal on the water quality and quantity indicators listed in Table 7.6.3-1 were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.6.3-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as discussed in Section 7.2.3.4.

TABLE 7.6.3-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON WATER QUALITY AND QUANTITY

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Water Quality and Quantity Indicator – Surface Water Quantity			
1.1 Localized alteration of natural drainage patterns during construction and operations	LSA	• Ensure the potential for soil erosion by water is reduced during construction activities by avoiding ponding of water or the unintentional channelization of surface water flow [Section 8.1]. • Maintain existing surface drainage across the Westridge Marine Terminal [Section 8.1]. • Install culverts in bar ditches when ramped to maintain drainage. Culvert specifications will be determined by the Inspector [Section 8.1]. • Remove drainage and erosion control devices and materials at all sites when the area is stabilized and no longer in use including infrastructure pads, permanent access, TWS (required for railway boring) and stockpile sites [Section 8.1]. • Establish long-term topsoil/root zone material storage berms at locations away from regular Westridge Marine Terminal operational activity and areas with potential for overland water flow and storage berm erosion [Section 8.4].	• Localized alteration of natural surface drainage patterns at the Westridge Marine Terminal.
2. Water Quality and Quantity Indicator – Groundwater Quality			
2.1 Localized change in the location of the groundwater/seawater interface	LSA	• Ensure that measures are taken to reduce the amount of water discharged to the subsurface [Section 8.1]. • Ensure that amount of pumping of groundwater is kept to a minimum to avoid ingress of seawater into water supply wells [Section 8.1].	• No residual effect identified.

Notes: 1 LSA = Water Quality and Quantity LSA.
2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.3.3 Potential Residual Effects

The potential residual environmental effect on the water quality and quantity indicators associated with the construction and operations activities at the Westridge Marine Terminal (Table 7.6.3-1) is localized alteration of natural surface drainage patterns at the Westridge Marine Terminal. The potential effect of localized change in the location of the groundwater/seawater interface is predicted to be eliminated through the implementation of mitigation measures (Table 7.6.3-1).

7.6.3.4 Significance Evaluation of Potential Residual Effects

Table 7.6.3-2 provides a summary of the significance evaluation of the potential residual environmental effects of construction and operations activities at the Westridge Marine Terminal on water quality and quantity. The rationale used to evaluate the significance of the residual environmental effect is provided below.

TABLE 7.6.3-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON WATER QUALITY AND QUANTITY

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Water Quality and Quantity Indicator – Surface Water Quantity									
1(a) Localized alteration of natural surface drainage patterns at the Westridge Marine Terminal.	Negative	LSA	Short-term	Isolated	Long-term	Low	High	High	Not significant

Notes: 1 LSA = Water Quality and Quantity LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of localized alteration of natural surface drainage patterns at the Westridge Marine Terminal was determined to be generally the same for the construction and operations activities at the Westridge Marine Terminal as for pump station construction and operations (Table 7.6.3-2, point 1[a]). The exception is the reversibility of localized alteration of drainage patterns, which for the Westridge Marine Terminal is considered to be long-term since natural drainage patterns will not be fully restored until decommissioning and abandonment. Table 7.4.3-2 and the accompanying discussion in Section 7.4.3.4 provide an evaluation of this potential residual effect and its significance on the surface water quantity indicator.

7.6.3.5 Summary

As identified in Table 7.6.3-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the water quality and quantity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operations activities at the Westridge Marine Terminal on water quality and quantity will be not significant.

7.6.4 Air Emissions

7.6.4.1 Assessment Indicators and Measurement Endpoints

Assessment indicators used in the evaluation of the potential effects of the construction and operation of the Westridge Marine Terminal on air emissions include primary emissions of CACs and VOCs; formation of secondary $PM_{2.5}$ and ozone; and emissions of H_2S and mercaptans. The rationale for selection of these indicators has been previously discussed in Sections 7.2.4 and 7.5.4.

Both quantitative and qualitative measurement endpoints are applied to assess the potential effects of Westridge Marine Terminal expansion and operation on the air emissions indicators. During the Westridge Marine Terminal expansion, construction equipment will emit CACs and VOCs. During operation, Westridge Marine Terminal is the Project's largest source of fugitive VOC, H_2S, and mercaptans emissions. As a result of the installation of TVAUs, emissions of some CACs are expected to decrease (Table 7.2.4-2).

7.6.4.2 Spatial Boundaries

The spatial boundaries for the study areas for primary pollutant emissions and formation of secondary pollutant are described in Section 7.5.4.2.

7.6.4.3 Project Associated Air Emissions

Estimated air emissions from Westridge Marine Terminal expansion and operation are described in Section 7.2.4.3 and summarized in Table 7.2.4-2.

7.6.4.4 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects on the air emissions indicators that are associated with the construction and operation activities at the Westridge Marine Terminal are listed in Table 7.6.4-1 and were based on the results of the literature review, desktop analysis, field work, interviews with design engineers, modelling, and consultation with regulatory authorities, and other stakeholders (Section 3.0), as well as the professional experience of the assessment team.

A summary of the mitigation measures provided in Table 7.6.4-1 was principally developed in accordance with Trans Mountain standards, accepted facility construction methods for construction-related activities, and industry and provincial regulatory guidelines including *Guidelines for Air Quality Dispersion Modelling in British Columbi*a (BC MOE 2008), Canadian Ambient Air Quality Standards (Government of Canada 2013) and BC ambient air quality objectives (BC MOE 2013a).

TABLE 7.6.4-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATION AT THE WESTRIDGE MARINE TERMINAL ON AIR EMISSIONS

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds			
1.1 Primary emissions of criteria air contaminants	RSA	• Trans Mountain will consult with and inform the City of Burnaby and neighbouring landowners of the existing Westridge Marine Terminal with the potential to be affected by emissions from construction activities, prior to the commencement of these activities [Section 7.0]. • Trans Mountain will reduce the duration that vehicles and equipment are allowed to sit and idle to less than one hour unless air temperatures are less than 0°C [Section 7.0]. • Ensure equipment is well-maintained during construction to minimize air and noise emissions [Section 7.0]. • Use multi-passenger vehicles for the transportation of crews to and from the Westridge Marine Terminal, as much as possible [Section 7.0]. • Control emissions to ambient air from new construction at the Westridge Marine Terminal so that concentrations of pollutants do not exceed Metro Vancouver Ambient Air Quality Objectives [Section 7.0].	• Increase in ambient concentrations of CACs.
1.2 Primary emissions of volatile organic compounds	RSA	• Install vapour recovery units to capture vapours from tankers during loading. • Complete engineering design to find suitable vapour destruction systems for VOCs and reduced sulphurs. Preliminary design considers an absorption vessel for removing sulphur compounds and activated carbon adsorption for removing hydrocarbons. Design of vapour recovery system will be completed during detailed engineering design.	• Increase in ambient concentrations of VOCs.

TABLE 7.6.4-1 Cont'd

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2. Air Emissions Indicator – Formation of Secondary Particulate Matter and Ozone			
2.1 Formation of secondary particulate matter and ozone	LFV	• All Project-related storage tanks are required to adhere to CCME standards that will reduce fugitive VOC emissions.	• Increase in ambient concentrations of secondary ozone and particulate matter. • Reduced visibility.
3. Air Emissions Indicator – Hydrogen Sulphide and Mercaptans			
3.1 Emissions of H_2S and mercaptans	RSA	• Install TVAUs and vapour recovery system at WMT.	• Increase in ambient ground-level concentrations of H_2S and mercaptans.

Notes: 1 RSA = Air Quality RSA; LFV = Lower Fraser Valley.
2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.4.5 Potential Residual Effects

The potential residual environmental effects on the air quality indicators associated with the construction and operation activities at the Westridge Marine Terminal (Table 7.6.4-2) are:

- an increase in ambient concentrations of CACs;
- an increase in ambient concentrations of VOCs;
- an increase in ambient concentrations of secondary ozone and particulate matter;
- reduced visibility; and
- an increase in ambient ground-level concentrations of H_2S and mercaptans.

7.6.4.6 Significance Evaluation of Potential Residual Effects

The significance evaluation of potential residual effects at the Westridge Marine Terminal follows the same combination of a quantitative and qualitative assessment of air emissions as for tank installation and operation in Section 7.5.4.6.

Detailed information is presented in the Air Emissions and Greenhouse Gas Technical Report (Volume 5C). Data for the quantitative assessment of ambient concentrations of CACs and VOCs are shown in Table 7.6.4-2. For some CACs, Project operation is expected to reduce total emissions at Westridge Marine Terminal from current base case emissions (Table 7.2.4-2). However, note that emission sources shift. In particular, emissions from ships at berth are expected to increase. Table 7.6.4-2 presents the greatest increase in ambient concentrations across all receptors. While many receptors are predicted to see a decrease in ambient concentrations, receptors that are affected strongly by emissions from ships at berth are predicted to see a net increase. Total Project case emissions of NH_3 are predicted to be *de minimus* (9 kg per year, Table 7.2.4-2). Therefore, no potential residual effects are expected during Project operation for primary emissions of CACs.

TABLE 7.6.4-2

DISPERSION MODELLING RESULTS FOR AMBIENT CAC AND VOC CONCENTRATIONS FOR EMISSIONS FROM WESTRIDGE MARINE TERMINAL AND COMPARISON WITH APPLICABLE REGULATORY STANDARDS (EXPRESSED AS NET CHANGE FROM EXISTING CONDITIONS) (in µg/m^3)

Pollutant[1]	Averaging Period	Project at Westridge Marine Terminal	MV Objective
Total Suspended Particulate (TSP)	24-hour	16.00	-
	Annual	0.04	-
Respirable Particulate Matter (PM_{10})	24-hour	15.97	50
	Annual	0.034	20
Inhalable Particulate Matter ($PM_{2.5}$)	24-hour	15.97	25
	Annual	0.025	8
Carbon Monoxide (CO)	1-hour	62.62	30,000
	8-hour	39.19	10,000
Nitrogen dioxide (NO_2)	1-hour	89.88	200
	24-hour	68.10	-
	Annual	5.83	40
Sulphur Dioxide (SO_2)	1-hour	20.18	450
	24-hour	5.08	125
	Annual	0.24	30
Benzene	1-hour	34.27	-
	Annual	0.60	-
Ethylbenzene	1-hour	0.84	-
Toluene	1-hour	24.26	-
	24-hour	4.35	-
Xylenes	1-hour	8.08	-
	24-hour	1.44	-

Note: 1 No primary emissions of NH_3 were modelled in CALPUFF, only the contribution of NH_3 to secondary formation of $PM_{2.5}$ was modelled in CMAQ (see Table 7.5.4-4).

A quantitative assessment was performed for H_2S and mercaptans on the basis of dispersion modelling and odour detection thresholds. Three-minute and 10-minute averages for H_2S and total mercaptans, respectively, were calculated by scaling predictions of maximum 1-hour average ambient ground-level concentrations. The results for each terminal are presented in Table 7.6.4-3. No exceedances of odour detection thresholds are predicted to occur.

TABLE 7.6.4-3

DISPERSION MODELLING RESULTS FOR H_2S AND TOTAL MERCAPTANS FOR THE WESTRIDGE MARINE TERMINAL (EXPRESSED AS NET CHANGE FROM EXISTING CONDITIONS) (in µg/m^3)

Component or Facility	H_2S 3-minute[2]	Total Mercaptans[1] 10-minute[2]
Westridge	0.0015	5.3
Odour detection threshold	*13.1*[3]	*13*[3]

Notes: 1 No individual species within the chemical group of mercaptans nor other additional species were predicted to exceed known odour detection thresholds (see the Air Quality and Greenhouse Gas Technical Report of Volume 5C for further information).

2 3-minute and 10-minute averages were calculated from 1-hour modelled data based on the model guideline for Ontario (Ontario MOE 2009).

3 Odour detection threshold for H_2S is the geometric mean air odour detection threshold reported by AIHA (1989) and Total Mercaptans threshold is based on the Ontario Air Standard for Total Reduced Sulphur (Ontario MOE 2007).

Table 7.6.4-4 provides a summary of the significance evaluation of the potential residual environmental effects of construction and operation activities at the Westridge Marine Terminal on air emissions.

TABLE 7.6.4-4

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON AIR EMISSIONS

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds									
1(a)	Increase in ambient concentrations of CACs.	Negative	RSA	Short to long-term	Isolated to periodic	Long-term	Low to medium	High	Moderate	Not significant
1(b)	Increase in ambient concentrations of VOCs.	Negative	RSA	Long-term	Continuous	Long-term	Low	High	High	Not significant
1(c)	Combined effects on the primary emissions of CACs and VOCs indicator (1[a] and 1[b]).	Negative	RSA	Long-term	Continuous	Long-term	Low	High	Moderate	Not significant
2.	Air Emissions Indicator – Formation of Secondary Particulate Matter and Ozone									
2(a)	Increase in ambient concentrations of secondary ozone and particulate matter.	Negative	LFV	Long-term	Continuous	Long-term	Medium	High	Moderate	Not significant
2(b)	Reduced visibility.	Negative	LFV	Long-term	Periodic	Long-term	Low	High	Moderate	Not significant
2(c)	Combined effects on the formation of secondary particulate matter and ozone indicator (2[a] and 2[b]).	Negative	LFV	Long-term	Continuous	Long-term	Medium	High	Moderate	Not significant
3.	Air Emissions Indicator – Hydrogen Sulphide and Mercaptans									
3(a)	Increase in ambient ground-level concentrations of H_2S and mercaptans.	Negative	RSA	Long-term	Continuous	Long-term	Low	High	Moderate	Not significant

Notes: 1 RSA = Air Quality RSA; LFV = Lower Fraser Valley.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The evaluation of significance of potential residual effects in Table 7.6.4-3, points 1(b), 1(c), 2(a), and 3(a) is determined to be the same for the construction and operation of the Westridge Marine Terminal as for the tank construction and operation. Table 7.5.4-6 and the accompanying discussion in Section 7.5.4 provide an evaluation of these potential residual effects at the Westridge Marine Terminal and its significance on the applicable air emissions indicators.

Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds

The following provides the evaluation of significance of potential residual effects on the primary emissions of CACs and VOCs indicator.

Increase in Ambient Concentrations of CACs

The increase in ambient ground-level concentrations of CACs is considered to have a negative impact balance. As shown in Table 7.6.4-4 point 1(a), the increase in ambient ground-level concentrations of CACs is confined to the Air Quality RSA. Air emissions are expected to change ambient concentrations of CAC's during Westridge Marine Terminal expansion; the frequency of these construction activities is rated as isolated, while the net increase in CAC emissions from operational activities will be periodic. The increase in CAC concentrations during the expansion is likely measurable but small compared to Metro Vancouver objectives. Project-related increases of ambient CAC concentrations are mostly small compared to Metro Vancouver objectives; for the 24-hour average $PM_{2.5}$ concentration, the Metro Vancouver objective is approached, but not exceeded (Table 7.6.4-2). Therefore, the magnitude is expected to be low to medium. The probability of this occurring is high, because the construction equipment will emit CACs. Because the cause-effect relationships are well understood but detailed information on construction equipment is unavailable, the confidence in the residual effects assessment is moderate. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Air Quality RSA – changes to ambient ground-level concentrations of CACs from construction are expected to occur within the Air Quality RSA.
- Duration: short to long-term – the event resulting in emissions of CACs is facility construction (short-term) and tankers at berth and some terminal equipment (boilers) (long-term).
- Frequency: periodic – the events resulting in emissions of CACs occur intermittently but repeatedly over the assessment period.
- Reversibility: long-term – emissions of CACs will continue for the life of the operating terminal but will cease when the facility is decommissioned.
- Magnitude: low to medium – the increase in ambient ground-level concentrations of CACs is expected to be small relative to existing conditions and not expected to approach regulatory limits.
- Probability: high – storage tank construction will result in emissions of CACs.
- Confidence: moderate – residual effects assessment is based on a good understanding of cause-effect relationships between construction and air emissions but reliant on vehicle and equipment estimates from previous projects.

Air Emissions Indicator - Formation of Secondary Particulate Matter and Ozone

The following provides the evaluation of significance of potential residual effects on the formation of secondary particulate matter and ozone indicator.

Reduced Visibility

Reduced visibility, as a result of increased ambient concentrations of particulate matter, is considered to have a negative impact balance. As shown in Table 7.6.4-4 point 2(b), reduced visibility is confined to the LFV photochemical model domain. Equipment use at the Westridge Marine Terminal will periodically contribute chemical precursors for secondary particulate matter formation. Currently, no visibility objectives or standards that could be approached exist. $PM_{2.5}$ concentrations, which can reduce visibility, are regulated, however, expected increases in ambient concentrations of $PM_{2.5}$ are small compared to the Canadian Ambient Air Quality Standards, and it is not expected that any location in the LFV will approach the Canadian Ambient Air Quality Standards for $PM_{2.5}$. Therefore, the change in visibility is considered to be of low magnitude. This reduced visibility could be caused over Project lifetime, and the reversibility is therefore long-term. The probability of this occurring is high. Confidence in the residual effects assessment is moderate, because the cause-effect between primary emissions and subsequent reduced visibility is reasonably well understood but the atmospheric chemistry is complex. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: LFV – reduced visibility expected to occur within the Lower Fraser Valley within the LFV photochemical modelling domain.
- Duration: long-term – emissions of precursors and subsequent reduced visibility are expected to occur for the operational life of the Westridge Marine Terminal and, therefore, are considered long-term.
- Frequency: periodic – precursor emissions from equipment used at Westridge Marine Terminal will cause the formation of secondary PM and reduced visibility to occur intermittently but repeatedly during operations.
- Reversibility: long-term – emissions of precursors and subsequent reduced visibility will extend for the life of the operating terminal. Reduced visibility is reversible as the precursor emissions will cease when the facility is decommissioned.
- Magnitude: low – the reduction in visibility caused by increased ambient $PM_{2.5}$ concentrations is expected to be small relative to existing concentrations but for some areas within the LFV might approach Canadian Ambient Air Quality Standards for $PM_{2.5}$.

- Probability: high – an increase in Project-related equipment use at Westridge Marine Terminal will result in precursor emissions for secondary particulate matter formation and lead to visibility reduction.
- Confidence: moderate – based on a good understanding of cause-effect relationships between the Project, air emissions, and atmospheric reactions; however, there is uncertainty with respect to non-Project emissions, and atmospheric chemical reactions are complex.

Combined Effects on Formation of Secondary Particulate Matter and Ozone

The increase in ambient ground-level concentrations of particulate matter and ozone and the reduction in visibility are considered to have a negative impact balance. As shown in Table 7.6.4-4 point 2(c), the increase in ambient ground-level concentrations of particulate matter and ozone and the reduction in visibility are confined to the LFV photochemical model domain. Emissions during operation at the Westridge Marine Terminal will contribute chemical precursors for secondary ozone formation continuously due to product working and standing losses from handling and storage and ship loading. The changes are considered to be of medium magnitude, because for some areas within the LFV, ambient ground-level concentrations of ozone already approach Canadian Ambient Air Quality Standards. Reversibility is long-term because primary emissions leading to secondary pollutant formation will continue over the life of the operating terminal. The probability of this occurring is high. Confidence in the residual effects assessment is moderate because of the complexity of atmospheric chemistry governing secondary pollutant formation. A summary of the rationale for all of the significance criteria for combined effects on secondary particulate matter and ozone is provided below.

- Spatial Boundary: LFV – changes to ambient ground-level concentrations of secondary PM and ozone and visibility reductions are expected to occur within the LFV photochemical modelling domain.
- Duration: long-term – the combined effects on secondary particulate matter and ozone are expected to occur for the operational life of the Westridge Marine Terminal and, therefore, are considered long-term.
- Frequency: continuous – the combined effects on secondary particulate matter and ozone (*i.e.*, mostly from VOC fugitive precursor emissions and combustion products causing formation of ozone) occur continuously during Westridge Marine Terminal operations.
- Reversibility: long-term – combined effects on secondary particulate matter and ozone reflect fugitive emissions of VOCs during operations at the terminals which will extend for the life of the operating terminal. Combined emissions are reversible as the increase in ambient particulate matter and ozone will cease when the facility is decommissioned.
- Magnitude: medium – the increase in ambient ground-level concentrations of particulate matter and ozone and reduction in visibility are expected to be small relative to existing conditions, but for some areas within the LFV, ambient ground-level concentrations of ozone might approach Canadian Ambient Air Quality Standards.
- Probability: high – an increase in Project-related product storage, handling, and loading as well as equipment use will result in precursor emissions, which contribute to secondary PM and ozone formation and reduced visibility.
- Confidence: moderate – based on a good understanding of cause-effect relationships between the Project, air emissions, and atmospheric reactions; however, there is uncertainty with respect to non-Project emissions, and atmospheric chemical reactions are complex.

7.6.4.7 Summary

As identified in Table 7.6.4-4, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the air emissions indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operation activities at the Westridge Marine Terminal on air emissions will be not significant.

7.6.5 Greenhouse Gas Emissions

As discussed in Section 7.2.5.3, during the construction phase at the Westridge Marine Terminal, dredging, dewatering, and other construction activities as well as operation of vehicles and product loading will result in GHG emissions. During the operations phase, most of the GHG emissions associated with the Westridge Marine Terminal will result from fugitives released during vapour combustion and product loading. Regular transportation, space heating, and equipment use during maintenance activities and normal operations, as well as fugitive emissions from storage tanks, associated valves and connectors, and ship holds are also sources of direct GHG emissions. Electricity consumption at the terminal will result in indirect GHG emissions. GHG emissions related to the construction and operations of the Westridge Marine Terminal are summarized in Table 7.2.5-5.

The assessment of effects on GHG emissions has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, Westridge Marine Terminal and pipeline reactivation), since GHG emissions associated with the construction and operation of each Project component are aggregated for the Project as a whole and then compared to provincial and federal GHG inventory totals.

The assessment of effects on GHG emissions for the Project as a whole is presented in Section 7.2.5. Table 7.2.5-8 and accompanying discussion in Section 7.2.5.3 provide an evaluation of potential residual effects of the construction and operation of the Westridge Marine Terminal on GHG indicators.

7.6.6 Acoustic Environment

Sections 7.2.6.1, 7.2.6.2 and 7.4.6 provide the assessment indicators, measurement endpoints, spatial boundaries and acoustic environment context for the assessment of potential effects of the proposed Westridge Marine Terminal expansion work on the acoustic environment.

7.6.6.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with proposed Westridge Marine Terminal expansion work on the acoustic environment indicators listed in Table 7.6.6-1 were based on the results of desktop analysis, modelling and engagement with regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.6.6-1 was principally developed in accordance with Trans Mountain standards and industry, federal, provincial and municipal regulatory guidelines as described in Section 7.2.6.4.

TABLE 7.6.6-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS OF THE WESTRIDGE MARINE TERMINAL ON THE ACOUSTIC ENVIRONMENT

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Acoustic Environment Indicator – Sound Levels			
1.1 Changes in sound levels during construction	LSA	• Adhere to all federal (*i.e.,* Environment Canada, *Motor Vehicle Safety Act*, *Oil and Gas Occupational Safety and Health Regulations*, Health Canada), and provincial (Noise Control, BC OGC, *Worker's Compensation Act*, *Occupational Health and Safety Regulations* [BC Reg 296/97 as amended] Section 7.2 [BC Reg. 382/2004, s.1]) and municipal guidelines and regulations for noise management [Section 7.0]. • Implement mitigation measures where night time activity (*e.g.,* HDD) on the facility site is located within 500 m of residences as outlined in the Noise Management Plan [Section 7.0]. • Ensure that Westridge Marine Terminal construction activities adhere to the City of Burnaby Noise and Sound Abatement Bylaw 1979 (Number 7332), including approved hours of work, unless otherwise approved by municipal authorities. Schedule construction activities during the period from 07:00 to 20:00, during weekdays, and 09:00 to 20:00, during weekends, if feasible [Section 7.0]. • Construction activities located within onshore or marine wildlife setback distances will be scheduled to occur within least risk windows or proceed with the approval of the appropriate regulatory authority [Section 7.0]. • Noise abatement and construction scheduling will be considered during noise-sensitive periods, to limit disruption to sensitive receptors (*i.e.,* neighbouring landowners, wildlife migratory periods, nesting birds) [Section 7.0]. • Enforce vehicle speed limits and inform contractor truck drivers and mobile equipment operators that engine retarder braking in urban areas is prohibited [Section 7.0]. • Consider the placement and orientation of equipment to be used at the Westridge Marine Terminal prior to construction in order to reduce the noise disturbance of residents and sensitive wildlife in the vicinity of the Westridge Marine Terminal [Section 7.0]. • Enclose noisy equipment and use baffles, where and when feasible, to limit the transmission of noise beyond the construction site [Section 7.0]. • Use only the size and power of tools necessary to limit noise from power tool operations [Section 7.0]. • Use vibratory methods of pile installation, to the extent feasible. Limit impact piling to daytime only, if feasible [Section 7.0]. • Locate stationary equipment, such as compressors and generators, away from sensitive wildlife, to the extent feasible, and follow the applicable municipal, provincial and federal guidelines [Section 7.0]. • Maintain noise suppression equipment on all construction machinery and vehicles in good order [Section 7.0].	• Increase in sound levels during construction period at the Westridge Marine Terminal.
1.1 Changes in sound levels during operations	LSA	• Review and analyse equipment specifications to ensure sound emissions from mechanical equipment are equal to or less than the sound emissions used in the Terrestrial Noise and Vibration Technical Report. • Ensure ground vehicles are well maintained, especially mufflers. • Use of off-road vehicles for inspection should be limited to week days.	• Increase in continuous sound levels from operations of new equipment at the Westridge Marine Terminal.

Notes: 1 LSA = Acoustic Environment LSA.

2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.6.2 Residual Effects

The potential residual environmental effects on the acoustic environment indicators associated with the construction and operations activities at the Westridge Marine Terminal (Table 7.6.6-1) are:

- increases in sound levels during construction period; and
- increase in continuous sound levels from operation of new equipment.

7.6.6.3 Significance of Residual Effects

Table 7.6.6-2 provides a summary of the significance evaluation of the potential residual environmental effects on the acoustic environment indicator resulting from Project activities at the Westridge Marine Terminal.

A quantitative assessment of the acoustic environment was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects of construction and operations activities at the Westridge Marine Terminal. The evaluation of significance of each of the potential residual effects for the acoustic environment relies primarily on the magnitude, duration and frequency of the potential change. The definitions for these elements are provided in Table 7.1-2. However, magnitude of residual effects requires further definition for the acoustic environment evaluation and is indicator specific. Magnitude for sound level has been defined based on the degree of compliance with provincial and Health Canada guidelines. Details on the guidelines and legislation used to establish the magnitude ratings can be found in the Terrestrial Noise and Vibration Technical Report.

The definitions of magnitude for the L_{eq} in dBA indicator for construction activities at the Westridge Marine Terminal are as follows.

- **Negligible:** Below BC OGC *Noise Control Best Practices Guideline* daytime ASL (56 and 61 dBA based on receptor).
- **Low:** Below BC OGC *Noise Control Best Practices Guideline* PSL daytime limits (61 and 66 dBA based on receptor) and Health Canada guidance of 75 dBA.
- **Medium:** Less than Health Canada 75 dBA guidance but greater than the BC OGC *Noise Control Best Practices Guideline* daytime PSL (61 and 66 dBA based on receptor).
- **High:** Greater than Health Canada 75 dBA guidance.

The sound levels indicator definitions of magnitude during operations at the Westridge Marine Terminal are as follows.

- **Negligible:** Below BC OGC *Noise Control Best Practices Guideline* nighttime ASL (46 and 51 dBA based on receptor).
- **Low:** Below BC OGC *Noise Control Best Practices Guideline* PSL nighttime limits (46 and 51 dBA based on receptor) and Health Canada %HA limit.
- **Medium:** Equal to or slightly lower than the BC OGC *Noise Control Best Practices Guideline* PSL nighttime limit or Health Canada %HA limit.
- **High:** Greater than either the BC OGC *Noise Control Best Practices Guideline* PSL nighttime limit or the Health Canada %HA limit.

TABLE 7.6.6-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON THE ACOUSTIC ENVIRONMENT

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Acoustic Environment – Sound Level									
1(a) Increase in sound levels during construction period.	Negative	Acoustic LSA	Short-term	Isolated	Short-term	Medium	High	Moderate	Not Significant
1(b) Increase in continuous sound levels from operating equipment.	Negative	Acoustic LSA	Long-term	Continuous	Long-term	Negligible to low	High	Moderate	Not Significant
1(c) Combined effects on the sound levels indicator (1[a] and 1[b]).	Negative	Acoustic LSA	Long-term	Continuous	Long-term	Negligible to low	High	Moderate	Not Significant

Notes: 1 LSA = Acoustic Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Acoustic Environment Indicator – Sound Levels

Increase in Sound Levels During Construction Period

The potential for the increase in daytime or nighttime sound levels for human receptors associated with construction at the Westridge Marine Terminal is considered to have a negative impact balance. Based on the results of the analysis in the Terrestrial Noise and Vibration Technical Report, the spatial extent of changes to sound levels from the proposed Westridge Marine Terminal expansion was limited to within the Acoustic Environment RSA. However, the significance of changes is based on the compliance with regulatory guidance for noise. Compliance with regulatory requirements occurs within the Acoustic Environment LSA. The duration of the sounds experienced at receptors is dependent on the activity; each type of sound will last only for the particular phase of construction (*e.g.,* earthworks, tank construction, foundations).

The frequency of sound emissions during each construction activity will be isolated, as construction is cyclic and involves use of mobile equipment and intermittent use of tools. Construction is assessed based on daytime activity only, in compliance with Burnaby Municipal Bylaw 7332. Additional mitigation planning that includes low noise equipment and limits on the types and duration of activities would be required if some activities are required at night. The effect is reversible in the short-term as sound level changes due to construction at the Westridge Marine Terminal will cease as soon as the construction stops.

The results of predictive modelling for construction of a terminal indicates the magnitude of changes in sound levels that will be experienced by people living within 1.5 km of a terminal. Noise controls that will be in use during the construction phase, particularly the use of silencers on mobile equipment, limiting nighttime construction to daytime hours wherever possible, and executing a communications plan with affected persons are expected to control the effects on changes in sound to within acceptable levels as established in the Terrestrial Noise and Vibration Technical Report of Volume 5C. Controlling the magnitude of sound levels effects also limits the spatial extent of the potential change.

The definition for magnitude follows the construction descriptors found in Section 7.6.6.3. The magnitude changes depending on the distance between the construction activities and the surrounding receptors. The highest predicted sound level due to construction activities at the closest affected receptor was predicted to be approximately 70 dBA. Other mitigation measures may be used along with quieter than predicted equipment to lower this sound level. Given the current information, the magnitude would be rated as medium.

The sound levels at the homes will vary throughout the day, and can be controlled through detailed planning and use of sound reduced equipment in densely populated areas. The detailed construction planning required to fully assess urban sound levels is not available at this stage of project planning. A detailed noise management plan that is used during the planning for construction in urban environments can reduce the potential sound levels. A summary of the rationale for all of the significance criteria is provided below (Table 7.6.6-2, point 1[a]).

- Spatial Boundary: Acoustic Environment LSA – compliance with the BC OGC *Noise Control Best Practices Guideline* are achieved within the Acoustic Environment LSA.
- Duration: short-term – the events causing changes in sound levels will occur only during the construction phase.
- Frequency: isolated – the events causing changes in sound levels will occur at residential dwellings during the construction phase.
- Reversibility: short-term – the period over which the change in sound levels extends is the construction period. However, sound level changes will cease when construction activities have finished.
- Magnitude: medium – the magnitude is medium or lower with the implementation of a detailed noise management plan for construction. High magnitude sound levels could occur if nighttime construction is required but can be mitigated to a medium effect with additional mitigation planning.
- Probability: high – based on the proximity of residences to the terminals.
- Confidence: moderate – based on the nature of data inputs.

Increase in Continuous Sound Levels from Operating Equipment

The potential for the increase in daytime or nighttime sound levels for human receptors associated with operations of the Westridge Marine Terminal is considered to have a negative impact balance. Noise from the normal operations of the proposed Westridge Marine Terminal expansion will be sound from pumps, ship loading, ship berthing and support equipment located on the site. Since this is an expansion of the existing terminal, the types of sounds would be similar to those already generated on the site.

The spatial extent of the sound level change is limited to the Acoustic Environment LSA. The duration of the terminal sound is long-term, throughout the life of the terminal. The frequency is continuous, since the Westridge Marine Terminal could operate 24 hours per day, 7 days per week. The effect is reversible as sound level changes stop as soon as the sound stops, which would be at terminal decommissioning.

The definition for magnitude follows the operation descriptors found in Section 7.4.6.3. This varies depending on the distance between the terminal and the surrounding receptors. The predicted sound level created by the Westridge Marine Terminal including the proposed expansion is approximately 49 dBA at the nearest homes west of the site, during the more stringent nighttime period. The predictions include tank terminal equipment, ship loading equipment, one ship idling at the berth, and one ship being manoeuvred to the berth by three tugs and the BC OGC mandated ambient sound level. The combination of ship being manoeuvred by tug was more conservative than having two ships loading. The 49 dBA results indicates a 3 dBA increase over ambient conditions, but is compliant with the BC OGC *Noise Control Best Practices Guideline* limit of 51 dBA at night for the level of development in the area. Given the current information, the magnitude would be rated as negligible to low. A summary of the rationale for all of the significance criteria is provided below (Table 7.6.6-2, point 1[b]).

- Spatial Boundary: Acoustic Environment LSA – compliance with the BC OGC *Noise Control Best Practices Guideline* are achieved within the Acoustic Environment LSA.
- Duration: long-term – the event causing the increase in sound levels is the operation of the Westridge Marine Terminal which occurs over the operational life of the terminal.
- Frequency: continuous – the operation of the Westridge Marine Terminal occurs continually over the assessment period. Ship movements will be periodic. These sound forms the normal cyclic sounds that will occur over the life of the operating terminal.

- Reversibility: long-term – the increase in sound levels during operations at the Westridge Marine Terminal will extend over the life of the operating terminal. All sound level changes are reversible as the sound will cease when the facility is decommissioned.
- Magnitude: negligible to low – with the implementation of appropriate mitigation measures from Table 7.6.6-2 and the Westridge Marine Terminal EPP, sound emitted from the Westridge Marine Terminal and ship loading activities is expected to be controlled within BC OGC *Noise Control Best Practices Guideline* and Health Canada guidance.
- Probability: high – the operations of the terminal will increase sound levels for nearby receptors.
- Confidence: moderate – the assessment is based on a combination of measured existing data, theoretical formulae and current Project design.

Combined Effects on Sound Levels

The evaluation of the combined effects of the construction and operations of the Westridge Marine Terminal on the acoustic environment considers collectively the assessment of the likely potential residual effects on the sound levels indicators. The residual effects for the sound levels indicator do not combine to result in new ratings for the various components since the occurrences of sound happen at different times during the Project. Therefore, the combined effects represents the worst-case or most negative effect for each evaluation criteria between the two residual effects (Table 7.6.6-2, point 1[c]). Effectively, this is the effects from Westridge Marine Terminal operations, as Westridge Marine Terminal construction is of short-term duration and reversibility. A summary of the rationale for all of the significance criteria of combined effects on sound levels is provided below.

- Spatial Boundary: Acoustic Environment LSA – compliance with the BC OGC Noise *Control Best Practices Guideline* are achieved within the Acoustic Environment LSA.
- Duration: long-term – the event causing the combined effects on sound levels reflects the operations of the Westridge terminal which occurs over the life of the operating terminal.
- Frequency: continuous – the event causing combined effects on sound levels reflects the operations of the Westridge Marine Terminal which occurs continually over the assessment period. Ship movements will be periodic. These sounds form the normal cyclic sounds that will occur over the operational life of the terminal.
- Reversibility: long-term – the combined effects on sound levels reflect operations at the Westridge Marine Terminal and will extend over the operational life of the terminal. All sound levels changes are reversible as the sound will cease when the facility is decommissioned.
- Magnitude: negligible to low – the combined effects on sound levels from the Westridge Marine Terminal and ship loading activities is expected to be controlled within BC OGC *Noise Control Best Practices Guideline* and Health Canada guidance with the implementation of appropriate mitigation measures.
- Probability: high – combined effects on sound levels which reflect the operations of the Westridge Marine Terminal are likely to occur.
- Confidence: moderate – the assessment is based on a combination of measured existing data, theoretical formulae and current Project design.

7.6.6.4 Summary

As identified in Table 7.6.6-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on acoustic environment indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual effects associated with the construction and operations of the construction and operations of the Westridge Marine Terminal on the acoustic environment will be not significant.

7.6.7 Vegetation

Sections 7.2.9.1, 7.2.9.2 and 7.2.9.3 provide the assessment indicators, measurement endpoints, spatial boundaries and ecological context for the assessment of potential effects of the proposed Westridge Marine Terminal expansion on vegetation.

7.6.7.1 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with the construction and operations of the Westridge Marine Terminal on vegetation indicators are listed in Table 7.6.7-1. These interactions are based on the results of the desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.6.7-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.9.4.

TABLE 7.6.7-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND THE RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON VEGETATION

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-Native Species Identified as a Concern			
1.1 Weed introduction and spread	RSA	• See recommended mitigation measures outlined in Table 7.4.9-1 Vegetation.	• Weed introduction and spread.

Notes: 1 RSA = Vegetation RSA.
2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.7.2 Potential Residual Effects

The potential residual environmental effect on vegetation indicators from Project activities associated with the construction and operations of the Westridge Marine Terminal (Table 7.6.7-1) is weed introduction and spread.

7.6.7.3 Significance Evaluation of Potential Residual Effects

Table 7.6.7-2 provides a summary of the significance evaluation of the potential residual environmental effect of the construction and operations of the Westridge Marine Terminal on vegetation. The rationale used to evaluate the significance of the residual environmental effect is provided below.

TABLE 7.6.7-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON VEGETATION

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-native Species Identified as a Concern									
1(a) Weed introduction and spread.	Negative	RSA	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant

Notes: 1 RSA = Vegetation RSA.
2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effect on the presence of infestations of provincial weed species and other invasive non-native species identified as a concern indicator (Table 7.6.7-2, point 1[a]) was determined to be the same for the construction and operations of the Westridge Marine Terminal as for pipeline construction and operations. The exception is low magnitude given the localized area of disturbance. Table 7.2.9-3 and the accompanying discussion in Section 7.2.9.6 provide an evaluation of the potential residual effect of project activities and their significance on this vegetation indicator.

7.6.7.4 Summary

As identified in Table 7.6.7-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect of high magnitude that cannot be technically or economically mitigated. Consequently, is it concluded that the residual environmental effects arising from the construction and operations of the Westridge Marine Terminal on vegetation will be not significant.

7.6.8 Marine Sediment and Water Quality

Marine sediment and water quality are important components of the marine environment as they are physical elements that support aquatic life. Marine sediments are formed by the accumulation of particulate matter that settles out of the water column, and may consist of anything from coarse gravel and sand to clay and organic matter. Human activities in the Burrard Inlet watershed have resulted in discharges from water and land-based sources over many years, which have led to locally or regionally elevated contaminant levels in sediments. Processes that occur in surface marine sediments (*e.g.,* diffusion to water, re-suspension during sediment disturbance, or accumulation by benthic organisms) can affect the local and global cycling of these contaminants. Because of these mechanisms, sediments may continue to release contaminants long after the sources have been eliminated and, therefore, have potential for adverse effects on living organisms and ecosystems.

Elevated levels of contaminants in seawater or sediment can present increased risk of toxicity to marine organisms. Project activities with potential to release existing contaminants (*e.g.,* in sediment) or introduce additional contaminants (*e.g.,* through discharges to Burrard Inlet) are assessed in this subsection.

7.6.8.1 Assessment Indicators and Measurement Endpoints

The process of selecting indicators for the assessment of marine sediment and water quality was guided by the potential effects identified for the expansion of the Westridge Marine Terminal (change in sediment quality and change in water quality), regulatory considerations (permits that could be required for the Project, screening criteria, and guidelines for protection of marine life), comments provided during engagement with Aboriginal communities, regulatory authorities, stakeholders and the general public, and the professional experience of the assessment team.

Table 7.6.8-1 lists the indicators used to assess potential effects on marine sediment and water quality, the quantitative measurement endpoints used and the rationale for their selection.

TABLE 7.6.8-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR MARINE SEDIMENT AND WATER QUALITY

Marine Sediment and Water Quality Indicators	Measurement Endpoints	Rationale for Indicator Selection
Marine sediment quality	• Comparison of sediment concentrations of selected contaminants that represent bitumen and refined products chemistry (light extractable petroleum hydrocarbons [LEPH], heavy extractable petroleum hydrocarbons [HEPH], PAH, [BTEX (benzene, toluene, ethylbenzene and xylene), volatile petroleum hydrocarbons [VPH]), other contaminants (PCB, metals) to: - *Canadian Environmental Protection Act 1999 (CEPA): Disposal at Sea Regulations* for the disposal of dredged material (SOR/2001-275) - CCME Interim Sediment Quality Guidelines (ISQG) and Probable Effects Levels (PEL) (CCME 2013) - Draft Burrard Inlet Sediment PAH Guidelines (Swain 2009) and Objectives for Burrard Inlet (Nijman 1990) - BC MOE working guidelines for sediment (Nagpal *et al.* 2006)	• Potential to release existing contaminants from sediment into the water column during construction activities (dredging for Westridge Marine Terminal berths). • Information required to assess options for sediment disposal (permit under *Disposal at Sea Regulations*).
Marine water quality	• Comparison of water concentrations of selected general parameters and contaminants that represent water chemistry (*e.g.,* metals, nutrients, total suspended solids [TSS], turbidity, salinity, total extractable hydrocarbon [TEH]) to: - permit limits for TEH (*Petroleum Storage and Distribution Facilities Storm Water Regulation* (BC MOE 2004) - CCME Water Quality Guidelines for the Protection of Aquatic Life (CCME 2013) - BC Approved Water Quality Guidelines (BC MOE 2013) - BC Working Water Quality Guidelines (Nagpal *et al.* 2006) - Ambient water quality objectives for Burrard Inlet Coquitlam-Pitt River area (Nijman 1990)	• Potential to release contaminants or TSS into Burrard Inlet during construction (*e.g.,* dredging) and operations (from treated stormwater). • Effluent characteristics will be described in a required permit.

7.6.8.2 Spatial Boundaries

Spatial boundaries for the assessment of potential Project effects on marine sediment and water quality are defined as follows.

- Project Footprint: the area directly affected by construction of the Westridge Marine Terminal.
- Marine Sediment and Water Quality LSA: the ZOI likely to be affected by construction and operations of the Westridge Marine Terminal, defined as the area within 500 m of the proposed water lease expansion.
- Marine RSA: the area where the direct and indirect influence of other activities could overlap with Project-specific effects and cause cumulative effects on marine sediment and water quality, defined as Burrard Inlet east of the First Narrows, including Indian Arm and Port Moody Arm.

The ZOI for the Marine Sediment and Water Quality LSA was selected to encompass the area over which sediments disturbed during in-water construction activities may disperse before settling to the seafloor.

Study area boundaries for marine sediment and water quality are shown on Figures 6.2-1 and 6.2-2.

7.6.8.3 Marine Sediment and Water Quality Context

The Westridge Marine Terminal is located in the Central Harbour of Burrard Inlet, which encompasses the area east of the Second Narrows and south of the entrance to Indian Arm. Though less developed than the Inner Harbour (between the First and Second Narrows), water and sediment quality has been affected by human activities related to residential, industrial, commercial and shipping activities over the years.

<u>Sediment</u>

Sediment quality in the waters surrounding the Westridge Marine Terminal reflects ambient conditions for Burrard Inlet and historical and current activities at the terminal.

Hydrocarbons contaminants (*e.g.,* PAH, LEPH, and HEPH) are the main parameters of concern for the Project, which involves shipping of hydrocarbons. Construction activities have the potential to disturb contaminants during dredging (release of small amounts of sediment) or during disposal. The extent of dredging required has not been finalized, but if required, it is expected to be within a small area along the shoreline to allow for geotechnical stability required for proposed infill. Dredging in deeper waters to provide increased under-keel clearance of vessels is not anticipated. The Environment Canada Disposal at Sea program provides a regulatory framework for evaluating disposal options for dredged sediment and screening criteria for disposal at sea. The province of *BC Contaminated Sites Regulation* provides a regulatory framework for evaluating disposal options on land. DFO provides work windows and best management practices (BMPs) for dredging and material handling.

Sediment quality in the Footprint, Marine Sediment and Water Quality LSA and Marine RSA is discussed in the Marine Sediment and Water Quality – Westridge Marine Terminal Technical Report of Volume 5C. The Footprint itself is relatively undisturbed and does not include the existing dock at the Westridge Marine Terminal, which is within the Marine Sediment and Water Quality LSA. Historical activities at the Westridge Marine Terminal resulted in elevated levels of PAHs, cadmium and mercury in subtidal sediment adjacent to the pier, as noted prior to dredging in 2006; following dredging, total PAH levels in sediment were 1.5 mg/kg or less (BGC Engineering Inc. 2006), below the screening criteria for disposal at sea (2.5 mg/kg) and the draft Burrard Inlet objective (1.68 mg/kg; Swain 2009). In 2007, a rupture of the Trans Mountain pipeline on Barnet Highway resulted in introduction of crude oil into Burrard Inlet through the storm drain infrastructure, which affected intertidal sediment; following clean up and remediation, sediment PAH levels have been below the Burrard Inlet draft objective (Stantec 2010, 2012).

The 2013 subtidal sediment sampling program conducted in the Footprint and Marine Sediment and Water Quality LSA provides the most recent and site-specific data for the Westridge Marine Terminal (see Marine Sediment and Water Quality – Westridge Marine Terminal Technical Report of Volume 5C). Results indicate generally good sediment quality, meeting the majority of disposal at sea screening criteria and the CCME sediment quality guidelines. There are some exceedances for metals, reflecting human activities in the Burrard Inlet watershed, at levels similar to other locations within the Marine RSA (BC MWLAP 2004d). The majority of sediment samples (53 of 54) met the disposal at sea screening criteria for total PAH of 2.5 mg/kg; the exception was one sample with 3.66 mg/kg. Hydrocarbons that could indicate the presence of fresh oil (LEPH, HEPH and BTEX) were not detectable. PCB levels were below detection in most samples and below the screening criterion in all but one sample collected from northwest of the proposed berths (0.276 mg/kg compared to the 0.1 mg/kg screening criterion). Copper, arsenic, lead and cadmium levels were higher than the screening guidelines and CCME ISQGs in some samples; however, maximum concentrations were lower than the CCME probable effects levels (PELs). Concentrations below the ISQG are not expected to be associated with any adverse biological effects, whereas concentrations above the PEL are expected to be frequently associated with adverse biological effects. Concentrations between the ISQG and the PEL represent the range in which effects are occasionally observed. Distribution of these metals in core samples (from surface to 2 m sampled) suggests a combination of natural and human-related sources.

- Arsenic levels reflect natural occurrence (similar levels at all depths throughout the sampling area, up to 10.9 mg/kg compared to ISQG of 7.24 mg/kg and PEL of 41.6 mg/kg).
- Cadmium and lead levels reflect human sources (levels higher than the ISQG only in the 0-0.5 m samples, throughout the sampling area; cadmium up to 0.75 mg/kg compared to screening criterion of 0.6 mg/kg, ISQG of 0.7 mg/kg and PEL of 4.2 mg/kg; lead up to 59.3 mg/kg compared to ISQG of 30.2 mg/kg and PEL of 112 mg/kg).
- Copper levels reflect both natural and human sources (levels higher than the ISQG at all depths sampled and throughout the sampling area, with highest concentrations in the 0-0.5 m interval; up to 88.3 mg/kg compared to ISQG of 18.7 mg/kg and PEL of 108 mg/kg).

The spatial distribution of PAHs and metals in the Footprint and Marine Sediment and Water Quality LSA reflects ambient sources of contaminants (*e.g.,* from stormwater runoff and vessel traffic) of a historical and current nature, with no specific areas of concern ("hot spots") identified.

Water

The waters near the Westridge Marine Terminal are well-circulated, with freshwater input from the Seymour River and tidal exchange in the Second Narrows (BIEAP 2011). General water quality characteristics in Burrard Inlet are discussed in the Marine Sediment and Water Quality – Westridge Marine Terminal Technical Report of Volume 5C. Ambient water quality, while generally considered good, is affected by release of contaminants from uncontrolled sources, such as the many stormwater outfalls in the area (BIEAP 2011, EVS Environmental Consultants 2003), vessel traffic and marinas. Small spills from equipment during construction or operations of the terminal are another potential source of hydrocarbons.

Discharges from petroleum handling facilities are managed under permit (*Waste Discharge Regulation* of the *Environmental Management Act* [BC MOE 2004]), and typically regulate hydrocarbon release, as indicated in the existing permit for the Westridge Marine Terminal.

Limited data are available for hydrocarbons in water within the Footprint and Marine Sediment and Water Quality LSA. The effluent discharge permit for the Westridge Marine Terminal requires monitoring of TEH monthly; monitoring reports for 2010 and 2011 indicate effluent met the permit requirement of < 5.0 mg/L TEH, and that levels were typically below detection (0.08-0.20 mg/L). PAH concentrations in water were measured in the Marine Sediment and Water Quality LSA and parts of the Marine RSA after the 2007 accidental oil release from the Trans Mountain pipeline into Burrard Inlet; levels were below the detection limit (0.05 µg/L) on the two dates sampled in 2007, with the exception of one sample collected from Port Moody (0.21 µg/L).

7.6.8.4 Potential Effects and Mitigation Measures

Effects Considerations

This subsection describes issues/effects that were considered for inclusion in the assessment of potential Project effects on marine sediment and water quality but were scoped out of the assessment. Some of these issues were raised through consultation with regulatory authorities and other stakeholders, and others were identified by the assessment team based on past experience with similar projects. For each issue/effect identified below, a rationale is provided for why it was not carried through the assessment.

Release of ballast and bilge water is not addressed in the marine sediment and water quality assessment for the Westridge Marine Terminal. These activities are highly regulated by Transport Canada through the *Canada Shipping Act, 2001*. The *Ballast Water Control and Management Regulations* (SOR/2006-129) govern release of ballast water, to avoid release of alien invasive species to local waters. Release of ballast water, which could occur at the Westridge Marine Terminal during cargo loading, is addressed in Section 7.6.9 Marine Fish and Fish Habitat. The *Vessel Pollution and Dangerous Chemicals Regulations* (SOR/2012-69) prohibit the release of untreated bilge water. Nonetheless, unregulated (accidental) discharges from any size of vessel may occur, and could affect marine water quality. This activity is further discussed in Section 4.3.13 of Volume 8A.

Identified Potential Effects

Potential effects associated with construction and operations activities at the Westridge Marine Terminal on the marine sediment and water quality indicators listed in Table 7.6.8-2 were identified based on the results of a literature review, desktop analysis, field work, engagement with regulatory authorities and other stakeholders (Section 3.0), and the professional experience of the assessment team. Given that berth construction details have not been finalized, and may or may not require dredging, the assessment assumes conservatively that some dredging may be required. Similarly, the proposed shoreline infill may require dredging; however, those details have not been finalized.

A summary of mitigation measures provided in Table 7.6.8-2 was principally developed in accordance with Trans Mountain standards and industry best practices, federal regulatory requirements (*Disposal at Sea Regulations*, *Fisheries Act*) and provincial regulatory requirements including the *Environmental Management Act*, which regulates discharge of effluent (*Petroleum Storage and Distribution Facilities Storm Water Regulation*) and disposal of contaminated materials (*Contaminated Sites Regulation*).

TABLE 7.6.8-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON MARINE SEDIMENT AND WATER QUALITY

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Marine Sediment and Water Quality Indicator – Marine Sediment Quality			
1.1 Change in sediment quality during construction	LSA	• Limit dredging to the extent feasible, for Westridge Marine Terminal construction [Section 8.2]. • Implement the least invasive method of dredging the marine environment (*i.e.*, clamshell dredging), if feasible, in order to reduce sedimentation [Section 8.2]. • Install sedimentation/turbidity control methods (*e.g.*, turbidity curtains) during activities associated with dredging of the marine environment (from onshore or from the marine environment) in order to limit the dispersion and effects of sedimentation on sensitive species. Turbidity curtains will be attached to a floatation boom and will extend from the sea surface to 1-2 m from the sea bottom, if feasible, or as per engineered design [Section 8.2]. • Remove seabed sediment during activities associated with dredging of the marine environment from onshore or from the marine environment, and place all excavated material on a barge deck located inside the turbidity curtain and remove for disposal on sea (if approved by appropriate regulatory authorities) or at an approved location on land (if material does not meet disposal at sea screening criteria) [Section 8.2]. • Use sediment disposal methods appropriate to sediment quality (to see if screening criteria are met or to be disposed of at a designated facility if sediment does not meet disposal at sea screening criteria) [Section 8.2].	• Release of hydrocarbons (PAH), PCBs and metals during construction, through dredging and disposal of sediment (if required).
2. Marine Sediment and Water Quality Indicator – Marine Water Quality			
2.1 Change in water quality during construction or operations	LSA	• Limit dredging to the extent feasible, for Westridge Marine Terminal construction [Section 8.2]. • Implement the least invasive method of dredging the marine environment (*i.e.*, clamshell dredging), if feasible, in order to reduce sedimentation [Section 8.2]. • Install sedimentation/turbidity control methods (*e.g.*, turbidity curtains) during activities associated with dredging of the marine environment (from onshore or from the marine environment) in order to limit the dispersion and effects of sedimentation on sensitive species. Turbidity curtains will be attached to a floatation boom and will extend from the sea surface to 1-2 m from the sea bottom, if feasible, or as per engineered design [Section 8.2]. • Implement a water quality monitoring program during marine construction activities (*i.e.*, dredging of the marine environment from onshore and/or the marine environment, marine drilling, pile installation, infilling, etc.) in order to assess the effectiveness of mitigation measures in place to reduce potential effects to water quality and sediment quality during construction. The monitoring program will assess total suspended solids (TSS) and turbidity within sediment plumes created as a result of marine construction. TSS and turbidity levels will be monitored to ensure these concentrations remain within the Canadian Council of Ministers of the Environment's (CCME) *Canadian Environmental Quality Guidelines* (CCME 2007). In the event that TSS concentrations exceed allowable limits outside of the construction area, water samples will be collected and tested for polycyclic aromatic hydrocarbons (PAHs) in order to assess the risk of spread of these contaminants. The distance required for monitoring will be determined based on consultation with DFO [Section 8.2]. • Install sediment fences at the base of cut/fill areas to reduce sediment discharge into the marine environment, where warranted [Section 8.1].	• Release of hydrocarbons (TEH) during operations, through release of stormwater from the vicinity of hydrocarbon storage facilities and from the pier. • Release of TSS during construction.

TABLE 7.6.8-2 Cont'd

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2.1 Change in water quality during construction or operations (cont'd)	See above	• Store bulk tanks containing hazardous materials (*e.g.,* fuel for construction equipment) in a bermed area lined with an impervious polyethylene liner. Containment berms will be large enough to contain 110% of the largest tank plus 10% of the aggregate tank volume within the containment area or as otherwise specified by regulatory requirements. Note that secondary storage for fuel storage tanks is required as noted above for volumes exceeding 1,000 L. Design and size secondary containment for hydrocarbons in accordance with applicable provincial and federal requirements. Remove any rainwater which accumulates within the containment structure if authorized by the Environmental Inspector. If there is a visible hydrocarbon sheen, the water in the containment structure will be collected for proper storage and disposed of at an approved facility [Section 7.0]. • Treat stormwater from hydrocarbon storage and handling areas for removal of hydrocarbons prior to discharge to Burrard Inlet during operations (oil/water separator as directed through the BC *Environmental Management Act* (*Petroleum Storage and Distribution Facilities Storm Water Regulation, Contaminated Sites Regulation*).	• See above.

Notes: 1 LSA = Marine Sediment and Water Quality LSA.
2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.8.5 Potential Residual Effects

The potential residual environmental effects on the marine sediment and water quality indicators associated with construction and operations activities at the Westridge Marine Terminal (Table 7.6.8-2) are:

- release of hydrocarbons (PAH), PCBs, metals and TSS during construction, through dredging and disposal of sediment (if required); and
- release of hydrocarbons (TEH) during operations, through release of stormwater from the vicinity of hydrocarbon storage facilities and piers.

7.6.8.6 Significance Evaluation of Potential Residual Effects

A combination of quantitative and qualitative assessments of marine sediment and water quality was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects, due to the existence of regulatory thresholds, standards and guidelines for indicators associated with this element. Consequently, the evaluation of significance of each of the potential residual effects relies on both the application of standards and guidelines and the professional judgment of the assessment team.

Table 7.6.8-3 provides a summary of the significance evaluation of the potential residual environmental effects of the construction and operations activities at the Westridge Marine Terminal on marine sediment and water quality indicators. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.6.8-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON MARINE SEDIMENT AND WATER QUALITY

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Marine Sediment and Water Quality Indicator – Marine Sediment Quality									
1(a)	Release of hydrocarbons (PAH), PCB and metals during dredging and disposal of sediment.	Negative	LSA	Short-term	Isolated	Short-term	Low	High	High	Not significant
2.	Marine Sediment and Water Quality Indicator – Marine Water Quality									
2(a)	Release of TSS in the water column during construction.	Negative	LSA	Short-term	Isolated	Short-term	Low	High	High	Not significant
2(b)	Release of hydrocarbons (TEH) during operations (treated stormwater).	Negative	LSA	Long-term	Periodic	Short-term	Low	High	High	Not significant
2(c)	Combined effects on the marine water quality indicator (2[a] and 2[b]).	Negative	LSA	Long-term	Periodic	Short-term	Low	High	High	Not significant

Notes: 1 LSA = Marine Sediment and Water Quality LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Marine Sediment and Water Quality Indicator – Marine Sediment Quality

The following subsection provides the evaluation of significance of the potential residual effect on the marine sediment quality indicator.

Release of Hydrocarbons (PAH), PCBs and Metals During Construction

Construction of the expanded Westridge Marine Terminal has the potential to affect marine sediment through release of existing contaminants during dredging or during disposal at sea. The Westridge Marine Terminal has been designed to reduce the amount of dredging needed; however, there is potential for small amounts of dredging at the berths or near the shoreline to improve geotechnical stability of proposed infill areas.

The use of mitigation measures such as clamshell dredges and turbidity curtains during construction (Table 7.6.8-2) is expected to effectively manage most of the adverse effects associated with dredging, should it be required. Adverse effects associated with release of sediment contaminants during dredging are unlikely to occur. The 2013 sediment sampling program conducted in the Footprint and Marine Sediment and Water Quality LSA indicated that contaminant levels in the area are low (Marine Sediment and Water Quality – Westridge Marine Terminal Technical Report of Volume 5C). Sediment quality was assessed for potential contaminants identified by Environment Canada (PAHs, LEPH, HEPH, BTEX, metals, PCBs), which could come from existing or historical Westridge Marine Terminal operations or the many ambient sources identified for Burrard Inlet (Balanced Environmental Services Inc. [BESI] 2010). Sediment quality generally meets screening criteria for disposal at sea and CCME sediment quality guidelines for PAH (exception with 1 of 39 samples, 1.5 times the screening criterion) and PCB (exception with 1 of 39 samples, 2.7 times the screening criterion), with both samples collected in areas away from potential dredge activity. Metals levels are the one potential area of concern. Copper, lead, and cadmium levels in surface sediment (0-0.5 m), and arsenic and copper at all depths sampled were present at levels higher than the CCME ISQG in all 29 locations sampled. Concentrations in the Footprint and Marine Sediment and Water Quality LSA are similar to those measured elsewhere in Burrard Inlet (BC MWLAP 2004d), so are consistent with ambient conditions. Exceedance of the ISQG and screening criteria does not in itself indicate that toxic effects will occur, as the guidelines are set conservatively to protect marine life. The metals concentrations are typically well below the PEL (the level above which adverse effects are frequently associated), suggesting low potential for toxicity if sediments are disturbed.

The maximum cadmium (0.75 mg/kg), lead (59 mg/kg), arsenic (10.9 mg/kg) and copper (88 mg/kg) levels are about 18%, 52%, 26% and 81%, respectively, of the PEL. The mean values for surface sediment (core and grab samples taken across the entire area) are lower than the ISQG for cadmium (0.50 mg/kg), lead (27.7 mg/kg) and arsenic (7.22 mg/kg) and above the ISQG for copper (61.7 mg/kg; 67% of the PEL). Overall, there is a low potential for toxicological effects on marine biota from sediment disturbance, and sediment dwelling organisms and benthic fish are already exposed to these metals levels.

The effect of sediment disturbance or disposal during dredging will be of short-term duration and reversibility and of low magnitude (Table 7.6.8-3, point 1[a]). There is high confidence in this conclusion, given that existing sediment quality meets either screening criteria for disposal at sea or, for metals, reflects ambient conditions for the Marine Sediment and Water Quality LSA and Marine RSA and is well below PEL; and that the effectiveness of the proposed mitigation measures (reducing the need to dredge through site selection; use of clamshell dredge and silt curtains for dredging) is well understood. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Sediment and Water Quality LSA – sediment disturbance and dispersal will be limited to the dredge area and a small area of the LSA where sediment may be dispersed.
- Duration: short-term – limited to the period of dredging during construction.
- Frequency: isolated – confined to the dredging period during construction.
- Reversibility: short-term – effect will cease within seven days of dredging (disturbed sediment will settle to the bottom again).
- Magnitude: low – residual effects are not detectable from existing (baseline) conditions; although it is noted that baseline conditions are not within the environmental and/or regulatory standards (CCME guidelines and disposal at sea criteria); however, no change from baseline conditions is expected.
- Probability: high – likely to be associated with dredging, should dredging occur.
- Confidence: high – there is a good understanding of the cause-effect relationships between sediment contaminant conditions and potential for adverse effects on marine life (with the caveat that there is considerable conservatism in the sediment quality guidelines used to assess potential toxicity), effectiveness of the mitigation measures, and site-specific data upon which to base the assessment.

Marine Sediment and Water Quality Indicator – Marine Water Quality

The following subsection provides the evaluation of significance of the potential residual effect on the marine water quality indicator.

Release of TSS During Construction

The use of mitigation measures during construction (Table 7.6.7-2) is expected to effectively manage most of the adverse effects on water quality associated with dredging, should it be required. A clamshell bucket typically releases about 1% of sediment during dredging, half near the bottom and half during movement to the surface (Schroeder and Ziegler 2004, Tavolaro 1984). This value is commonly used to model sediment plumes from dredging (*e.g.,* Fissel *et al.* 2006). Movement of any sediment plume associated with dredging will be restricted through use of a turbidity curtain if feasible. Modeling of sediment plumes for another port development project (proposed NGPLP terminal in Kitimat Arm) indicated that the highest concentrations of released sediment (as TSS) would occur near the dredge site at the bottom of the water column, and decrease rapidly with distance (Fissel *et al.* 2006). In that example, TSS levels were predicted to be below the CCME and BC water quality guideline maximum (an increase over baseline of 25 mg/L TSS) and to be above the CCME and BC water quality guideline mean (5 mg/L over background) only in the immediate dredging location. The mean guideline is more appropriate to continuous dredging activities. Although modeling of a sediment plume has not been conducted for this Project, a similar localized effect would be expected for Westridge Marine Terminal construction, and would be influenced by time of year, volume of dredged material, duration of dredging, particle size of the sediment and local tides and currents.

The effect of increased TSS levels during dredging will be of short-term duration and reversibility and of low magnitude (Table 7.6.8-3, point 2[a]). There is high confidence in this conclusion, given that the effectiveness of the proposed mitigation measures (reducing the need to dredge through site selection; use of clamshell dredge and turbidity curtains for dredging) is well understood. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Sediment and Water Quality LSA – increased TSS levels will be limited to the dredge area and a small area of the LSA where sediment may be dispersed.
- Duration: short-term – limited to the period of dredging during construction.
- Frequency: isolated – confined to the dredging period during construction.
- Reversibility: short-term – effect will cease within seven days of dredging (disturbed sediment will settle to the bottom again).
- Magnitude: low – residual effects will be measurable but within environmental and/or regulatory standards (CCME and BC guidelines).
- Probability: high – likely to be associated with dredging, should dredging occur.
- Confidence: high – there is a good understanding of the cause-effect relationships between sediment disturbance and generation of TSS, effectiveness of the mitigation measures, and site-specific data upon which to base the assessment.

Release of Hydrocarbons (Treated Stormwater) During Operations

Operation of the expanded Westridge Marine Terminal has the potential to affect marine water and, indirectly, sediment, through release of surface water (stormwater) runoff from the site. Runoff may contain hydrocarbons, metals and suspended sediment. of these, hydrocarbons are of particular concern at an oil shipping terminal, and are regulated in the discharge permit for the facility. Increased contaminant concentrations can lead to toxicity in marine biota. Given the many existing sources of stormwater contaminants in Burrard Inlet (BESI 2010), there is a confounded environment where it is difficult to identify specific contaminant sources.

The current and future mitigation measure is to direct runoff from the hydrocarbon handling areas to a stormwater treatment facility before release to Burrard Inlet. The existing facility has operated under a BC MOE discharge permit since 1974 (amended April 2005), which applies to oil/water separators for runoff from the jet fuel storage areas, with release of treated water into Burrard Inlet through two outfalls. The permit sets limits on effluent quantity and quality to protect the marine receiving environment. Effluent is monitored monthly for TEH (limit 5.0 mg/L) and once a year for toxicity (limit of 100% result from 96 hr LC50 for salmonid species). The annual average discharge limit is 26 m^3 per day, with a maximum discharge of 415 m^3 per day. Monitoring of TSS and metals is not required under the permit. The most recent stormwater monitoring reports from 2010 and 2011 show that TEH met the permit requirement and was below the detection limit (which ranged from 0.08-0.20 mg/L) in all samples and that effluent passed the 96 hr LC50 toxicity test. These results indicate good system performance and maintenance practices.

Stormwater discharge from the expanded terminal will also be treated to remove oil from water; the collection system and treatment facility will be expanded to ensure this. Surface water from the loading area of the dock and the process areas of the foreshore (*e.g.,* around vapour recovery units) will be directed to the oil/water separator and discharged through the existing outfall to Burrard Inlet. The dock roadway and all other areas outside of the process areas will continue to drain directly to Burrard Inlet. Conditions similar to baseline are expected, as the new treatment facility will have the same permit requirements (stipulated under the *Petroleum Storage and Distribution Facilities Storm Water Regulation*) and discharged water will be in compliance with the permit. However, it is possible the expanded facility will result in stormwater concentrations closer to the permit limit than the currently reported levels below the detection limit (greater volume of oil on site; the current system treats stormwater from the jet fuel storage area and jet fuel evaporates more quickly than oil).

Residual effects of treated stormwater release may include a small but measurable increase in hydrocarbons in water within a small mixing area around the outfalls; this is not predicted to result in toxicity risks to aquatic life, as the permit limits were set to protect biota. There may also be a localized change in temperature (temperature of effluent is closer to that of ambient air than to seawater), metal levels or salinity (freshwater discharge into seawater), similar to that associated with inputs from watercourses. With the use of a stormwater treatment facility to mitigate effects, the residual environmental effects on water quality are considered to be low magnitude and to occur in an area where there are many similar sources of contaminants (Table 7.6.8-3, point 2[a]).

The effect of stormwater discharge will be long-term but low magnitude (detectable but well within environmental and regulatory standards), and reversible in the short-term. There is high confidence in this conclusion, given the good understanding of cause-effect relationships (permit limits are set to protect sensitive marine organisms), effectiveness of the current and proposed mitigation measures (well-established method of stormwater treatment, subject to regular inspection and maintenance), and professional experience. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Sediment and Water Quality LSA – rapid dilution of treated stormwater within a short distance of the outfall (the outfall is located in the LSA).
- Duration: long-term – stormwater discharges will occur throughout the operations phase.
- Frequency: periodic – effluent release will occur intermittently but repeatedly over the assessment period (during rainfall events).
- Reversibility: short-term – each event is reversible after the release ends; however, the overall effect of stormwater discharge will not stop until the end of operations.
- Magnitude: low – site runoff will be within permit requirements, which are set to protect marine aquatic biota; expansion of Westridge Marine Terminal facilities will not result in quantifiable changes in measurable parameters as there will be no change from existing conditions.
- Probability: high – given the rainfall regime in the Project area.
- Confidence: high – there is a good understanding of the cause-effect relationships between Westridge Marine Terminal operations and stormwater, and effectiveness of the stormwater treatment facility is well known (proven mitigation technology).

Combined Effects on Marine Water Quality

The combined effects on marine water quality from release of TSS during construction (dredging) and hydrocarbons during operations (from treated stormwater) are the same as discussed as separate effects in the preceding sections. Because one effect occurs during construction and the other during operations, there will be no overlap in the two effects. As a result, combined residual Project effects on water quality will include a low magnitude increase in TSS levels, of short-term duration and reversibility during construction and a small but measurable increase in hydrocarbons in water within a small mixing area around the outfalls during operations (within permit levels, low in magnitude, long-term in duration and short-term in reversibility); both effects would be limited to the Marine Sediment and Water Quality LSA in an area where there are many similar sources of contaminants.

The effect of stormwater discharge will be long-term but low magnitude (detectable but well within environmental and regulatory standards), and reversible in the short-term. There is high confidence in this conclusion, given the good understanding of cause-effect relationships (permit limits are set to protect sensitive marine organisms), effectiveness of the current and proposed mitigation measures (well-established method of stormwater treatment, subject to regular inspection and maintenance), and professional experience.

A summary of the rationale for all of the significance criteria is provided below, based primarily on the effects during operations.

- Spatial Boundary: Marine Sediment and Water Quality LSA – rapid dispersion of TSS or dilution of treated stormwater within a short distance of the outfall (the outfall is located in the LSA).
- Duration: long-term – given that stormwater discharges will occur throughout the operations phase.
- Frequency: periodic – effluent release will occur intermittently but repeatedly over the assessment period (during rainfall events).
- Reversibility: short-term – each event is reversible after the release ends; however, the overall effect of stormwater discharge will not stop until the end of operations.
- Magnitude: low – site runoff will be within permit requirements, which are set to protect marine aquatic biota; expansion of Westridge Marine Terminal facilities will not result in quantifiable changes in measurable parameters as there will be no change from existing conditions.
- Probability: high – given the rainfall regime in the Project area.
- Confidence: high – there is a good understanding of the cause-effect relationships between Westridge Marine Terminal operations and stormwater, and effectiveness of the stormwater treatment facility is well known (proven mitigation technology).

7.6.8.7 Summary

As identified in Table 7.6.8-3, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on marine sediment and water quality indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operations activities at the Westridge Marine Terminal on marine sediment and water quality will be not significant.

7.6.9 Marine Fish and Fish Habitat

Marine fish have high ecological, economic and cultural importance in BC. They support valuable commercial, recreational and Aboriginal food, social and ceremonial (FSC) fisheries, they provide food for a diversity of marine and terrestrial birds and mammals, and they have cultural value that transcends their economic and ecological importance. This subsection considers the potential effects of the construction and operations of the Westridge Marine Terminal on marine fish and their habitats. Key issues for marine fish and fish habitat were identified through discussions with federal regulatory authorities, including DFO, Environment Canada and PMV, feedback received from public participants at open houses and ESA Workshops held in the Lower Mainland and southern Vancouver Island, and the professional judgment of the assessment team. Key issues identified for marine fish and fish habitat are listed below:

- potential loss or alteration of marine fish habitat during construction of the Westridge marine Terminal;
- potential injury or mortality of marine fish during construction of the Westridge Marine Terminal; and
- potential introduction of invasive species during discharge of ballast water at the Westridge Marine Terminal.

This subsection considers only those effects that could arise during routine construction and operational activities at the Westridge Marine Terminal. For an assessment of the potential effects of an accidental hydrocarbon release at the Westridge Marine Terminal, the reader is referred to Section 8.0 of Volume 7.

7.6.9.1 Assessment Indicators and Measurement Endpoints

The process for selecting indicators for the assessment of marine fish and fish habitat began by identifying marine fish habitats and marine fish species known to occur in Burrard Inlet that could be affected by activities associated with the expansion of the Westridge Marine Terminal. This was refined by focusing on those habitats and species that support commercial, recreational and/or Aboriginal FSC fisheries. For the habitat-based indicators, all marine habitat types potentially affected by terminal construction were considered. For the species-based indicators, marine fish and invertebrates representative of broader taxonomic groups were considered. Preference was given to species that are: likely to occur seasonally or year-round in the terminal area; sensitive to the physical activities associated with terminal construction; and considered to be of conservation concern. The final selection of indicators took into consideration: experience gained during previous projects with similar ecological conditions and potential issues; feedback from regulators, Aboriginal communities and stakeholders; and professional experience of the assessment team.

The indicators selected to assess potential effects of the expansion of the Westridge Marine Terminal on fish and fish habitat are: marine riparian habitat; intertidal habitat; subtidal habitat; Dungeness crab (*Cancer magister*); inshore rockfish (*Sebastes* spp.); and Pacific salmon (*Oncorhynchus* spp.). The rationale for the selection of each of these indicators is provided in Table 7.6.9-1.

The measurement endpoints for marine fish and fish habitat include both quantitative and qualitative measurement of potential Project effects. For the habitat-based indicators, the measurement endpoint is the area of habitat altered or lost as a result of terminal construction. This was calculated based on the most current terminal engineering and design plans. For the species-based indicators, the measurement endpoints are: the change in productive capacity of suitable habitat as a result of terminal construction; and the likelihood of injury or mortality resulting from in-water construction activities. Productive capacity is defined as the maximum natural capacity of habitats to produce healthy fish, safe for human consumption, or to support or produce aquatic organisms upon which fish depend. Suitable habitat is defined as any habitat used by a given species during one or more life stages for rearing, foraging, spawning or migrating. The change in productive capacity was qualitatively assessed for each indicator species based on the amount of suitable habitat altered or lost as a result of terminal construction. In-water construction activities that have the potential to disturb marine fish were also considered in the assessment of change in productive capacity. The likelihood of injury or mortality was qualitatively assessed for each of the indicator species based on its known or inferred spatial and temporal distribution and its sensitivity to Project activities. Table 7.6.9-1 provides a summary of the measurement endpoints considered for each indicator.

TABLE 7.6.9-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR MARINE FISH AND FISH HABITAT

Marine Fish and Fish Habitat Indicators	Measurement Endpoints	Rationale for Indicator Selection
Marine riparian habitat	• Area of habitat altered or lost (m^2)	• Will be affected by terminal construction. • Provides nutrient inputs to the nearshore marine environment. • Consideration of NEB *Filing Manual* requirements for fish and fish habitat in Table A-2.
Intertidal habitat	• Area of habitat altered or lost (m^2)	• Will be affected by terminal construction. • Inhabited by numerous sessile marine species (*e.g.,* algae and invertebrates). • Used by numerous mobile marine species (*e.g.,* fish and invertebrates) for rearing, foraging, spawning and migrating. • Consideration of NEB *Filing Manual* requirements for fish and fish habitat in Table A-2.
Subtidal habitat	• Area of habitat altered or lost (m^2)	• Will be affected by terminal construction. • Inhabited by numerous sessile marine species (*e.g.,* algae and invertebrates). • Used by numerous mobile marine species (*e.g.,* fish and invertebrates) for rearing, foraging, spawning and migrating.
Dungeness crab (*Cancer magister*)	• Change in productive capacity of suitable habitat • Likelihood of injury or mortality	• Representative benthic invertebrate. • Important Area for Dungeness crab, as identified by DFO, overlaps with the Marine Fish and Fish Habitat LSA. • Supports commercial, recreational and Aboriginal fisheries. • Consideration of NEB *Filing Manual* requirements for fish and fish habitat in Table A-2.

TABLE 7.6.9-1 Cont'd

Marine Fish and Fish Habitat Indicators	Measurement Endpoints	Rationale for Indicator Selection
Inshore rockfish (*Sebastes* spp.)	• Change in productive capacity of suitable habitat • Likelihood of injury or mortality	• Representative demersal finfish. • Suitable rocky habitat present within the Marine Fish and Fish Habitat LSA. • Rockfish Conservation Area (RCA) overlaps with the LSA. • Includes species of conservation concern. • Supports commercial, recreational and Aboriginal fisheries. • Consideration of NEB *Filing Manual* requirements for fish and fish habitat in Table A-2.
Pacific salmon (*Oncorhynchus* spp.)	• Change in productive capacity of suitable habitat • Likelihood of injury or mortality	• Representative pelagic finfish. • Important Area for Pacific salmon, as identified by DFO, overlaps with the Marine Fish and Fish Habitat LSA. • Important prey for marine birds and marine mammals. • Supports commercial, recreational and Aboriginal fisheries. • Consideration of NEB *Filing Manual* requirements for fish and fish habitat in Table A-2.

7.6.9.2 Spatial Boundaries

Spatial boundaries for the assessment of potential Project effects on marine fish and fish habitat are defined as follows.

- Project Footprint: the area directly affected by construction of the Westridge Marine Terminal.
- Marine Fish and Fish Habitat LSA: the ZOI likely to be affected by construction and operations of the Westridge Marine Terminal, defined as the area within 500 m of the proposed water lease expansion.
- Marine RSA: the area where the direct and indirect influence of other activities could overlap with Project-specific effects and cause cumulative effects on marine fish and fish habitat. This includes the area of Burrard Inlet east of the First Narrows, including Indian Arm and Port Moody Arm.

Study area boundaries for marine fish and fish habitat are shown on Figures 6.2-1 and 6.2-2.

7.6.9.3 Marine Fish and Fish Habitat Context

The Westridge Marine Terminal is located in the Central Harbour of Burrard Inlet, which encompasses the area east of the Second Narrows and south of the entrance to Indian Arm. Though less developed than the Inner Harbour (between the First and Second Narrows), numerous commercial and industrial developments in the Central Harbour have led to the modification of natural shoreline habitats. A study by Haggarty (2001) concluded that 27.8% of the approximately 38 km of shoreline habitat in the Central Harbour has been modified by human activity. In the Inner Harbour, human development has led to the alteration of 79.7% of the total shoreline habitat. Most of this alteration has been in the form of docks, rip rap, and seawalls. Approximately 34% of the 158 km of shoreline in the Marine RSA and 44% of the 2.3 km of shoreline in the Marine Fish and Fish Habitat LSA has been classified as man-made (BC MFLNRO 2005).

The original Westridge Marine Terminal dock was constructed in 1957 using wood piles and decking. At that time the shoreline south and west of the dock was extended seaward using rock and sediment fill. This marine reclamation area provided a working surface for construction equipment and was needed for piping and other infrastructure associated with the terminal. Over the course of the ensuing decades, the dock was upgraded several times. The original wood piles were replaced with large diameter steel piles, the wood decking was replaced with steel and concrete trestle and loading platform, and concrete caissons were constructed to support the loading platform and associated infrastructure. Large rip rap was also added along most of the shoreline to reinforce the area of infill.

As a result of historic development at the Westridge Marine Terminal, approximately 480 m of the 710 m (68%) of shoreline within the Westridge Marine Terminal water lot has been entirely replaced with fill material. This includes the length of shoreline between the western boundary of the water lot and the existing loading trestle. To the east of the trestle, the upper intertidal zone has been in-filled to support the CN rail line, while the mid and low intertidal zones remain largely natural.

7.6.9.4 Potential Effects and Mitigation Measures

Effects Considerations

This subsection describes issues/effects that were considered for inclusion in the assessment of potential Project effects on marine fish and fish habitat but were scoped out of the assessment. Some of these issues were raised through consultation with Aboriginal communities, regulatory authorities and other stakeholders, and others were identified by the assessment team based on past experience with similar projects. For each issue/effect identified below, a rationale is provided for why it was not carried through the assessment.

Introduction of Aquatic Invasive Species Due to Ballast Water Discharge

Aquatic invasive species (AIS) are non-native aquatic species that are intentionally or unintentionally introduced to Canadian waters by human activity and whose introduction will likely cause damage to the ecosystem, existing species, the economy, or human well-being (Johannessen and McCarter 2010). Introduced species that do not cause measurable damage are known as alien species, rather than invasive species, and alien and invasive species are collectively called non-native species (Johannessen and McCarter 2010). The absence of natural predators in Canadian waters means that AIS can spread rapidly and displace native species through direct competition for food and habitat and through habitat alteration (DFO 2013b). AIS can be very detrimental to both Canadian biodiversity and the economy. In Canada, AIS have already been implicated in both the vast reductions in, or outright extinction of, indigenous fish and the resulting devastation of local fisheries (DFO 2013b).

The main pathways through which invasive species enter and spread through Canadian waters include shipping, recreational and commercial boating, the use of live bait, the aquarium/water garden trade, live food fish, unauthorized introductions and transfers, and canals and water diversions (DFO 2013b). The rate at which AIS are being introduced into Canadian waters nearly doubled during the second half of the 20th century as compared to the first half (DFO 2013b). Ballast water in ships is considered to be the single greatest source of new AIS (DFO 2013b).

Ballast water is brought on board a vessel to increase the draft, change the trim, regulate the stability, or to maintain stress loads within acceptable limits (Transport Canada 2010). Vessels are designed to carry cargo; therefore, vessels transiting without cargo require ballast to ensure safe and optimal operating conditions (Transport Canada 2010). Ambient water is pumped into ballast tanks or empty cargo holds, increasing draft of the vessel and resulting in greater stability and manoeuvrability. Once a vessel arrives at a terminal and is ready for loading, ballast water is released and the cargo takes the place of the ballast, ensuring adequate draft for safe navigation according to the vessel's original design. Ballast may be used to adjust trim (the position of the vessel in water, where the bow, stern and sides ideally sit in the same depth of water) by adjusting ballast in various areas until the vessel sinks or floats to the desired markings. Vessels typically carry some ballast water when carrying a full load, to adjust draft for increased stability during inclement weather and to compensate as fuel is consumed during transit (Transport Canada 2010).

Ballast water that is pumped into vessels in foreign ports can contain foreign aquatic organisms. Although grates or mesh installed on ballast water intakes prevent larger objects or organisms from entering the ship's hull while ballast water is pumped into the ballast tanks or cargo holds, they do not screen out smaller organisms such as bacteria and microscopic algae, or plants and animals (Transport Canada 2010). Aquatic organisms taken up in ballast water at one port of call may be released at another port of call during ballast exchange where they can spread and become established.

There are at least 89 non-native species in the Strait of Georgia, representing nearly three times the number of non-native species in other parts of coastal BC (Johannessen and McCarter 2010, Levings *et al.* 2002). According to Johannessen and McCarter (2010), the number of non-native species reported in the Strait of Georgia has increased 40-fold over the last century; although they note that this increase is likely due in part to increased awareness and surveillance and the resolution of long-standing taxonomic issues. Aquaculture, estuarine circulation patterns, and international shipping have been identified as the main pathways of introduction in the Strait of Georgia (Gillespie 2007, Johannessen and McCarter 2010, Levings *et al.* 2002). Along the BC coast, the Japanese mahogany clam (*Nuttallia obscurata*) and dinoflagellates of the genus *Alexandrium* are thought to have been introduced in ballast water (Rankin *et al.* 2004, Transport Canada 2010). To date, no detrimental effects from non-native species in the Strait of Georgia have been identified (Johannessen and McCarter 2010, Levings *et al.* 2002).

The most effective way to mitigate the introduction of AIS is to regulate and manage pathways of introduction (DFO 2013b). In Canadian waters, the release of ballast water is regulated by the *Ballast Water Control and Management Regulations* (*Ballast Water Regulations*) pursuant to subsection 35(1) and section 190 of the *Canada Shipping Act*. According to Transport Canada (2012), the purpose of the *Ballast Water Regulations* is to protect waters under Canadian jurisdiction from non-indigenous aquatic organisms and pathogens that can be harmful to ecosystems by minimizing the probability of future introductions of harmful aquatic organisms and pathogens from ships' ballast water while protecting the safety of ships. Ballast water is considered managed if it is exchanged, treated, transferred to a reception facility once sediment has settled into tanks, or retained onboard the vessel (Transport Canada 2012). The *Ballast Water Regulations* outline a number of mandatory ballast water management procedures related to ballast water management plans, ballast water exchange and treatment, reporting requirements, compliance and enforcement, and research.

A ballast water management plan outlines the processes and procedures for the safe and effective management of ballast water. Under the *Ballast Water Regulations*, owners of Canadian and foreign vessels must ensure the preparation of the ballast water management plans and ensure that a copy of the plan is carried on board and the processes and procedures in the plan are carried out.

The *Ballast Water Regulations* outline a set of procedures for ballast water exchange or treatment prior to discharge in waters under Canadian jurisdiction. These procedures are based on the International Maritime Organization (IMO) *Guidelines for Ballast Water Management and Development of Ballast Water Management Plans* and the IMO *Guidelines for Ballast Water Exchange*. All ships entering Canadian waters must exchange ballast water outside the 200 nautical mile limit of Canada's exclusive economic zone (Transport Canada 2010). Exchange of ballast water in deep ocean areas or open seas lowers the probability that harmful aquatic organisms and pathogens be transferred in ships ballast water (Transport Canada 2012). If offshore exchange is not feasible for safety reasons such as poor weather, ballast exchange is allowed in designated alternate exchange zones (Transport Canada 2010). Loaded vessels coming from outside waters normally carry some residual ballast water onboard. Before a vessel can take on ballast in tanks containing residual ballast water and subsequently discharge it in Canadian waters, ensure that the residual ballast water has been exposed to salinity conditions equivalent to mid-ocean ballast exchange (Transport Canada 2012).

Transport Canada inspectors may inspect a vessel to determine whether the vessel is in compliance with the *Ballast Water Regulations*. The inspection process may include inspection of the ballast water record book, ballast water management plan, sampling of the vessels ballast water, and any other documentation or assistance as required by the inspector (Transport Canada 2012). Vessels may also be boarded to collect ballast water samples for scientific analysis to further research the effectiveness of ballast water management (Transport Canada 2012).

Ships can choose to treat ballast water before entering Canadian waters instead of exchanging it. Under the *Ballast Water Regulations*, treated ballast water must meet the Ballast Water Performance Standard specified in Regulation D-2 of the IMO *Regulations for the Control and Management of Ships' Ballast Water and Sediments* to be acceptable (Transport Canada 2012).

The *Ballast Water Regulations* also establish reporting requirements for ship operators. The Master of a ship destined for a Canadian port must complete a ballast water reporting form and send it to Transport Canada as soon as possible after a management process is performed (Transport Canada 2012). If a ship is unable to comply with the legislation prior to entering Canadian water, they are required to notify Transport Canada at least 96 hours before entry into Canada's territorial sea and provide an explanation as to the inability to carry out exchange, and what equivalent process the ship intends to carry out to minimize the threat of introduction of AIS (Transport Canada 2012).

Trans Mountain will encourage shippers to comply with all federal laws and legislation regarding ballast water management, including the *Canadian Shipping Act* and the *Ballast Water Control and Management Regulations*. Compliance with the *Ballast Water Regulations* will minimize the likelihood that aquatic invasive species will be introduced during ballast water exchange. Therefore, the introduction of aquatic invasive species due to ballast water discharge was not considered further in this assessment.

Behavioral Disturbance of Marine Fish and Invertebrates Due to Vessel Noise

Exposure to sound typically includes a measure of the received sound level and the duration of the sound signal (Popper and Hastings 2009a). In general, there are two types of anthropogenic sounds: short pulses of high-intensity sounds such as those from blasting, pile driving, and seismic guns; and long-lasting, low-intensity sounds that result in increased background noise such as noise from vessels (Popper and Hastings 2009b).

Several reviews on the effects of anthropogenic sounds on fish and invertebrates have concluded that there is lack of empirical data about the effects of underwater noise on marine fish and invertebrates and very little is known about the potential effects (Hastings and Popper 2005, Moriyasu *et al.* 2004, Popper and Hastings 2009a,b). Potential effects of anthropogenic sound on fish and invertebrates include physical injury or mortality and behavioural responses (Hastings and Popper 2005, Moriyasu *et al*. 2004, Popper and Hastings 2009a,b). There are no criteria or thresholds for the effects underwater noise produced by vessels on marine fish or invertebrates; however, noise from vessels is not likely to be of sufficient intensity to cause physical injury or mortality to marine fish (Popper and Hastings 2009b). Therefore, these effects were not considered further. Underwater noise from vessels berthed at the Westridge Marine Terminal could potentially trigger behavioural responses by marine fish and, therefore, this potential effect was considered for inclusion in the assessment.

The effects of short-term and long-term exposure to underwater noise from vessels on marine fish and invertebrate behaviour are unknown and studies on the effects of anthropogenic sound on fishes have largely been focused on acoustic disturbances associated with explosives, pile driving, and seismic air guns (Moriyasu *et al.* 2004, Popper and Hastings 2009a). Nearly all studies to date on behavioural responses of fish to sound have been conducted in a laboratory setting, which does not provide insight as to how animals will behave in their natural habitat (Popper and Hastings 2009a,b). Furthermore, Popper and Hastings (2009b) note that it is very difficult to extrapolate data on the effects of sound between different fish species and sound sources. Potential behavioural responses of fish to anthropogenic sounds include no change in behavior, small temporary movements for the duration of the sound, large movements that displace fish from their normal locations, and large-scale changes in migration routes (Popper and Hastings 2009b). In theory, the large-scale displacement of a fish or invertebrate population from foraging, spawning, rearing, or migration areas could potentially affect its long-term survival.

Marine fish and invertebrates located near tankers berthed at the Westridge Marine Terminal may respond to the underwater noise by moving away from the sound source for the duration of the disturbance, but there is no evidence in the literature that suggests vessel noise will result in the large-scale displacement of fish or invertebrate populations from foraging, spawning, rearing, or migration areas or otherwise affect their distribution or abundance. This conclusion is supported by the existing overlap of areas of high shipping activity and Pacific salmon migration areas, such as Haro Strait, and the Fraser and Columbia rivers; and Dungeness crab fishing areas, such as the Strait of Georgia. Therefore, behavioural disturbance to marine fish and invertebrates due to underwater noise from Project-related marine vessels was not considered further in this assessment.

Identified Potential Effects

Expansion of the Westridge Marine Terminal will involve the construction of three new loading berths capable of handling Aframax-sized tankers, two trestles, and a utility dock for small tugs and workboats (Figure 6.2-1). These structures will be supported by approximately 220 steel pipe piles (maximum size 1,500 mm) driven into the marine sediment and rock-socketed into the underlying bedrock. A small amount of dredging may be required around the inner west berth to provide underkeel clearance; however, no underwater blasting is required. The expansion of the marine infrastructure will require some onshore development, including the installation of two new 762 mm OD (NPS 30) delivery pipes, vapour recovery units, maintenance sheds and electrical sheds, and a terminal operations control building. Due to the limited space available between the existing CN rail line and the foreshore, marine reclamation (*i.e.,* infilling) will be required to accommodate the new onshore infrastructure.

Construction activities associated with the expansion of the Westridge Marine Terminal have the potential to directly and indirectly affect marine fish and fish habitat through:

- alteration or loss of marine fish habitat;
- change in productive capacity of marine fish habitat; and
- injury or mortality of marine fish.

Activities associated with routine operations at the Westridge Marine Terminal are not expected to result in measurable effects to marine fish and fish habitat. Potential effects of an accidental hydrocarbon release at the Westridge Marine Terminal are discussed in Volume 7.

The potential effects associated with construction activities at the Westridge Marine Terminal on the marine fish and fish habitat indicators are listed in Table 7.6.9-2 and were based on the results of a literature review, desktop analysis, field work, engagement with regulatory authorities and other stakeholders (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.6.9-2 was principally developed in accordance with federal regulatory guidelines, industry best management practices, and the professional experience of the assessment team.

Section 35(1) of the federal *Fisheries Act* prohibits works or undertakings that will result in serious harm to fish that are part of a commercial, recreational or Aboriginal fishery, or fish that support such a fishery. Serious harm is defined as the death of fish or any permanent alteration to, or destruction of, fish habitat. However, section 35(2) qualifies this prohibition, in that it allows for the authorization of serious harm to fish by the Minister of Fisheries and Oceans, or through legislation.

In 2012, amendments to the *Fisheries Act* received Royal Assent. Policy and legislation have now been developed to support the new fisheries protection provisions of the *Fisheries Act*, which will focus on the sustainability and ongoing productivity of recreational, commercial and Aboriginal fisheries. In November 2013, amendments proposed to the *Fisheries Act* came in to force. New guidance and policy that accompanies these changes to the *Fisheries Act* now apply. The previous long-term policy objective of DFO was the achievement of an overall “net gain” of the productive capacity of fish habitats (DFO 1986). That policy’s objective was guided by the “no net loss” principle where DFO strived to balance unavoidable habitat losses with habitat compensation on a project-by-project basis. The management of effects to fish resulting from habitat degradation or loss remain the primary focus of DFO’s new Fisheries Protection Policy, as proponents are directed to avoid, mitigate and offset harmful impacts to fish and fish habitat (DFO 2013a).

Under DFO’s previous Policy for the Management of Fish Habitat, authorizations under section 35(2) of the *Fisheries Act* were only granted where habitat losses were unavoidable and the proponent could demonstrate that there would be no net loss of the productive capacity of fish habitat (DFO 1986). To meet DFO’s guiding principle of no net loss, habitat compensation, which involves the creation of new fish habitats or the restoration or enhancement of existing fish habitats, was typically required. Wherever possible, DFO urged proponents to pursue compensation measures that would achieve a net gain in the productive capacity of fish habitats. Although DFO’s new Fisheries Protection Policy focuses on the ‘productivity of fisheries’ rather than the ‘productive capacity of fish habitats’, the overall objective is largely the same: minimize harmful impacts to fish and fish habitats. Where impacts cannot be avoided or completely mitigated, offset measures (*i.e.*, compensation measures) are required. Since the new Fisheries Protection Policy was released only weeks before the filing date, this assessment of potential Project-related effects to marine fish and fish habitat is primarily written using language from DFO’s previous Policy for the Management of Fish Habitat (*e.g*., ‘no net loss’, ‘net gain’, ‘productive capacity’, ‘habitat compensation’). However, both the old policy and the new Fisheries Protection Policy were considered by the assessment team in developing this assessment and in determining appropriate mitigation measures.

The principal mitigation measure for marine fish and fish habitat is the implementation of a marine fish habitat compensation/offset program. A detailed marine fish habitat compensation/offset plan will be developed during the permitting phase of the Project (*i.e.,* post-regulatory review). This plan will quantify the amount of marine fish habitat affected by construction of the Westridge Marine Terminal (based on final engineering and design plans), identify and describe the compensation/offset measures that will be implemented to offset the effects to marine fish habitat (*e.g.,* creation of new habitats or enhancement/restoration of existing habitats), and discuss how the compensation/offset measures will ensure there is no net loss of productive capacity. The plan will also present a habitat effectiveness monitoring program that will be conducted to ensure the compensation/offset measures are successful. Key resources that will be used to guide the development of this program include the *Practitioners Guide to Habitat Compensation for DFO Habitat Management Staff* (DFO 2013c), the *Decision Framework for the Determination and Authorization of Harmful Alteration, Disruption or Destruction of Fish Habitat* (DFO 1998), and the new *Fisheries Protection Policy* (DFO 2013a).

To minimize the potential for injury or mortality to marine fish, all dredging and infilling works will be completed within the DFO least-risk work window for Burrard Inlet, which is from August 16 to February 28. If this becomes impractical, timing will be determined in consultation with DFO. In addition, a crab salvage program will be implemented within the dredge and fill footprint immediately prior to the commencement of dredging and infilling to reduce potential injury or mortality to Dungeness crabs. Crabs will be collected using baited traps and relocated to a nearby site, outside of the Marine Fish and Fish Habitat LSA.

Due to the time required to install the large number of piles (anticipated 2 years), it will not be possible to schedule this activity during the DFO least-risk window. However, additional mitigation measures will be applied during pile installation to minimize, if not eliminate, potential injury or mortality to marine fish. As illustrated in Table 7.6.9-5 (see assessment of *Injury or Mortality to Inshore Rockfish Due to Underwater Noise Produced During Pile Driving*, below), noise levels produced during pile driving are highly variable and situation-specific. However, use of a vibratory driver generally produces sound pressure levels (SPLs) that are roughly 25 dB lower (sound exposure levels [SELs] of 10-15 dB lower), on average, than those produced by an impact hammer in a comparable setting and does not produce the high impulse signatures of impact pile driving (Illingworth and Rodkin Inc. 2007, McCauley and Salgado Kent 2008). The preferred installation method is therefore vibratory driver, for its decreased noise production.

Where a vibratory driver cannot be used due to engineering constraints (*e.g*., unfavourable substrate conditions), an impact hammer will likely be used. If an impact or hydraulic hammer is required for pile installation, Trans Mountain will implement several mitigation measures when driving the piles. These recommendations are in accordance with Best Management Practices for Pile Driving and Related Operations (BMPs) for driving steel pipe piles with a diameter greater than 609 mm (24 inches). The BMPs were developed by the BC Marine and Pile Driving Contractors Association (2003) to minimize impacts to fish and fish habitat. Bubble curtains will be deployed over the full length of the wetted pile to assist in attenuating sound levels. A hydrophone will be used to monitor pressure levels during pile-driving, so as to reduce potential fish injury or mortality. This hydrophone will also be monitored at the onset of pile-driving to confirm the assumptions concerning source levels, potential exceedance of the interim criteria for fish harm (SPL of 208 dB re: 1µ; Popper *et al.* 2006), and effectiveness of mitigation measures.

Bubble curtains are a standard mitigation method for impact pile driving. While there are a variety of styles, they all rely on the same basic principle: surrounding the pile with air assists in attenuating the noise produced during impact. When designed and used effectively, bubble curtains have generally been shown to provide a reduction in SPLs and SELs of between 10 and 15 dB (Illingworth and Rodkin Inc. 2007). Actual attenuation values will vary depending on factors such as design of the bubble curtain, installation, current velocity, water depth, and substrate type (Koschinski 2011). Should use of a vibratory driver not be technically feasible, details concerning appropriate type and usage of bubble curtains will be discussed with DFO.

TABLE 7.6.9-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON MARINE FISH AND FISH HABITAT

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Marine Fish and Fish Habitat Indicator – Marine Riparian Habitat			
1.1 Loss of marine riparian habitat	Footprint	• Limit shoreline clearing to what is absolutely necessary for Project construction. • Implement a marine fish habitat compensation/offset program to ensure there is no net loss of the productive capacity of marine fish habitats.	• Loss of marine riparian habitat due to construction activities.
2. Marine Fish and Fish Habitat Indicator – Intertidal Habitat			
2.1 Loss of intertidal habitat	Footprint	• Limit the area of infill to what is absolutely necessary for Project construction. • Implement a marine fish habitat compensation/offset program to ensure there is no net loss of the productive capacity of marine fish habitats.	• Loss of intertidal habitat due to construction activities.
3. Marine Fish and Fish Habitat Indicator – Subtidal Habitat			
3.1 Loss of subtidal habitat	Footprint	• Limit the area of infill to what is absolutely necessary for Project construction. • Limit the number of piles to what is absolutely necessary for Project construction. • Implement a marine fish habitat compensation/offset program to ensure there is no net loss of the productive capacity of marine fish habitats.	• Loss of subtidal habitat due to construction activities.
4. Marine Fish and Fish Habitat Indicator – Dungeness Crab			
4.1 Decrease in productive capacity of suitable habitat for Dungeness crab	LSA	• Limit the extent of in-water works to what is absolutely necessary for Project construction. • Reduce the risk of sedimentation into areas of fish habitat by properly installing appropriate terrestrial erosion and sediment control measures and marine sediment/turbidity control measures, as required [Section 8.2]. • Implement a marine fish habitat compensation/offset program to ensure there is no net loss of the productive capacity of marine fish habitats.	• Decrease in productive capacity of suitable habitat for Dungeness crab due to construction activities.
4.2 Injury or mortality to Dungeness crab	Footprint	• Limit the extent of in-water works to what is absolutely necessary for Project construction. • Prior to the commencement of marine infilling and dredging, implement a crab salvage program to trap and relocate Dungeness crabs away from in-water construction areas [Section 8.2]. • Reduce the risk of sedimentation into areas of fish habitat by properly installing appropriate terrestrial erosion and sediment control measures and marine sediment/turbidity control measures, as required [Section 8.2]. • Conduct all dredging and infilling works within the DFO least-risk timing window for Burrard Inlet (August 16-February 28) to minimize the potential for injury or mortality of Dungeness crab. If this becomes impractical, timing will be determined in consultation with DFO [Section 8.2].	• Injury or mortality of Dungeness crab due to burial or crushing during infilling and/or dredging.
5. Marine Fish and Fish Habitat Indicator – Inshore Rockfish			
5.1 Decrease in productive capacity of suitable habitat for inshore rockfish	LSA	• See recommended mitigation measures outlined in potential effect 4.1 of this table.	• Decrease in productive capacity of suitable habitat for inshore rockfish due to construction activities.

TABLE 7.6.9-2 Cont'd

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
5.2 Injury or mortality to inshore rockfish	LSA	• Limit the extent of in-water works to what is absolutely necessary for Project construction. • Use a vibratory method of pile installation, where possible [Section 8.2]. • Deploy bubble curtains during pile installation to reduce underwater noise levels where an impact hammer is required for pile installation [Section 8.2]. • Conduct an acoustic survey in order to establish the effectiveness of the bubble curtain, prior to the commencement of the pile installation activity [Section 8.2]. • Reduce the risk of sedimentation into areas of fish habitat by properly installing appropriate terrestrial erosion and sediment control measures and marine sediment/turbidity control measures, as required [Section 8.2]. • Conduct all dredging and infilling works within the DFO least-risk timing window for Burrard Inlet (August 16-February 28) to minimize the potential for injury or mortality of inshore rockfish. If this becomes impractical, timing will be determined in consultation with DFO [Section 8.2].	• Injury or mortality to inshore rockfish due to burial or crushing during infilling and/or dredging. • Injury or mortality to inshore rockfish due to underwater noise produced during pile driving.
6. Marine Fish and Fish Habitat Indicator – Pacific Salmon			
6.1 Decrease in productive capacity of suitable habitat for Pacific salmon	LSA	• See recommended mitigation measures outlined in potential effect 4.1 of this table.	• Decrease in productive capacity of suitable habitat for Pacific salmon due to construction activities.
6.2 Injury or mortality to Pacific salmon	LSA	• Limit the extent of in-water works to what is absolutely necessary for Project construction. • Use a vibratory method of pile installation, where possible [Section 8.2]. • Deploy bubble curtains during pile installation to reduce underwater noise levels where an impact hammer is required for pile installation [Section 8.2]. • Conduct an acoustic survey in order to establish the effectiveness of the bubble curtain, prior to the commencement of the pile installation activity [Section 8.2]. • Reduce the risk of sedimentation into areas of fish habitat by properly installing appropriate terrestrial erosion and sediment control measures and marine sediment/turbidity control measures, as required [Section 8.2]. • Conduct all dredging and infilling works within the DFO least-risk timing window for Burrard Inlet (August 16-February 28) to minimize the potential for injury or mortality of Pacific salmon. If this becomes impractical, timing will be determined in consultation with DFO [Section 8.2].	• Injury or mortality of Pacific salmon due to burial or crushing during infilling and/or dredging. • Injury or mortality to Pacific salmon due to underwater noise produced during pile driving.

Notes: 1 LSA = Marine Fish and Fish Habitat LSA.
2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

7.6.9.5 Potential Residual Effects

The potential residual environmental effects on the marine fish and fish habitat indicators associated with construction activities at the Westridge Marine Terminal (Table 7.6.9-2) are:

- loss of marine riparian habitat, intertidal habitat, and subtidal habitat due to construction activities;
- decrease in productive capacity of suitable habitat for Dungeness crab, inshore rockfish, and Pacific salmon due to construction activities;
- injury or mortality to Dungeness crab, inshore rockfish, and Pacific salmon due to crushing or burial during infilling and/or dredging; and

- injury or mortality to inshore rockfish and Pacific salmon due to underwater noise produced during pile driving.

7.6.9.6 Significance Evaluation of Potential Residual Effects

The approach used to evaluate the significance of potential residual effects on marine fish and fish habitat was both quantitative and qualitative. For the effect of habitat loss, the areal extent of habitat affected by construction of the Westridge Marine Terminal was quantified using the most recent Project engineering and design plans, while the relative importance of the habitat to each indicator species and the resultant effect on productive capacity was assessed qualitatively. For the effect of injury or mortality, the area over which benthic organisms could be crushed or buried was quantified to the extent possible, as were the source levels of underwater noise that could potentially cause harm to fish. However, given the difficulty in predicting actual numbers of marine organisms injured or killed as a result of in-water construction, the magnitude of potential losses and the resultant effect on a species' population were assessed qualitatively. In determining the significance of potential residual effects on marine fish and fish habitat, special attention was given to the provisions of the *Fisheries Act* (and associated policies) that prohibit harm to fish and fish habitat. The evaluation of significance also relied on the professional judgment of the assessment team.

Table 7.6.9-3 provides a summary of the significance evaluation of the potential residual environmental effects of construction activities at the Westridge Marine Terminal on marine fish and fish habitat. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.6.9-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON MARINE FISH AND FISH HABITAT

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Marine Fish and Fish Habitat Indicator – Marine Riparian Habitat									
1(a)	Loss of marine riparian habitat due to construction activities.	Negative	Footprint	Short-term	Isolated	Permanent	Low	High	High	Not significant
2.	Marine Fish and Fish Habitat Indicator – Intertidal Habitat									
2(a)	Loss of intertidal habitat due to construction activities.	Negative	Footprint	Short-term	Isolated	Permanent	Low	High	High	Not significant

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Marine Fish and Fish Habitat Indicator – Marine Riparian Habitat

The following subsection provides the evaluation of significance of the potential residual effect on the marine riparian habitat indicator.

Loss of Marine Riparian Habitat Due to Construction Activities

Construction of the marine infrastructure and expansion of onshore facilities at the Westridge Marine Terminal will result in the loss of marine riparian habitat, intertidal habitat, and subtidal habitat. Marine riparian vegetation along the shoreline will be cleared to accommodate the new land-based infrastructure (*e.g.,* vapour recovery units, pipe racks) and to allow for construction of the marine trestles. Marine reclamation will result in the loss of intertidal and nearshore subtidal habitats within the existing Westridge Marine Terminal water lot. The rip rap (*i.e.,* large angular rock) used to armour the outer surface of the fill area will provide habitat for intertidal and subtidal biota, partially offsetting the losses attributed to infilling. The installation of steel pipe piles will also result in the loss of some soft sediment subtidal habitat.

The areal extent of marine fish habitat affected by construction of the Westridge Marine Terminal has been estimated based on the most current Project engineering and design plans, and is provided in Table 7.6.9-4. These values are considered to be conservative but may be adjusted following detailed terminal engineering.

TABLE 7.6.9-4

TYPE AND AMOUNT OF MARINE FISH HABITAT AFFECTED BY EXPANSION OF THE WESTRIDGE MARINE TERMINAL

Habitat Type	Effect Type	Area of Habitat Affected (m^2)	Description of Habitat
Marine riparian habitat	Loss[1]	2,685	Narrow fringe (~2-4 m wide) of small shrubs, brambles and other herbaceous plants
Intertidal habitat	Loss[1]	5,470	Primarily steep rip rap, with a small area of boulder/cobble with interspersed sand and gravel
	Creation[2]	3,770	Rip rap
Subtidal habitat	Loss[1]	17,100	Primarily soft sediment (sand and mud) with a small area of rip rap adjacent to the existing loading berth
	Creation[2]	5,550	Rip rap
Total	Loss	25,255	Marine riparian vegetation, intertidal habitat and subtidal habitat
	Creation[2]	9,320	Intertidal and subtidal rip rap

Notes: 1 Habitat permanently lost due to Project construction.

2 Habitat created as a direct result of Project construction.

Habitat lost as a result of construction of the Westridge Marine Terminal will decrease the productive capacity of marine fish habitats within the Marine Fish and Fish Habitat LSA. The degree to which a given species will be affected depends on the type and amount of habitat affected, the local and regional availability of the habitat, and the importance of the habitat for rearing, spawning or migration.

Marine riparian habitat provides a number of ecological functions including water quality and pollution abatement, wave energy absorption, terrain formation and stabilization, microclimate regulation, nutrient input, and habitat structure (Brennan and Culverwell 2004, Lemieux *et al.* 2004). As a result, marine riparian habitat contributes to the productive capacity of nearshore marine fish habitats (Lemieux *et al.* 2004, Levings and Jamieson 2001). Marine riparian habitat features and biological assemblages in the Marine Fish and Fish Habitat LSA were observed during the marine riparian survey conducted at the Westridge Marine Terminal on September 26, 2012 (see Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C). Within the existing Westridge Marine Terminal water lot, marine riparian vegetation is limited to a narrow fringe of small shrubs, brambles and weeds. A total of 38 vascular plant species were identified during the survey; common species included asters, ferns, grasses, holly, horsetail, morning-glory, peas, plantains, rushes, saxifrages, and various shrubs. This habitat has been heavily altered by past development, and likely provides limited value in terms of fish habitat.

Construction of the Westridge Marine Terminal will result in the loss of approximately 2,685 m^2 of marine riparian habitat, which is considered to have a negative impact balance. While this loss will be permanent, the associated loss of productive capacity will be offset through the construction of compensation/offset habitat. Specific compensation/offset measures will be determined in consultation with DFO, Aboriginal communities, local stewardship groups and other interested parties during the permitting phase of the Project. One option that has been been implemented successfully for other marine development Projects in BC is the creation of subtidal rock reefs. The ecological benefits of constructing a subtidal reef are myriad. The solid rock foundations of a reef provide anchoring sites for algae and invertebrates, leading to increased diversity and productivity. Crevices and interstitial spaces within a reef provide habitat for a variety of commercially harvested fish and invertebrates. The open matrix of a well-constructed reef also promotes exposure to tidal flushing that increases food and oxygen availability within the reef structure itself. Fish are attracted to the structural complexity of subtidal reef structures and the algal species (*e.g.*, kelps) growing on them. Through direct herbivory and bacterial decomposition, algal detritus forms the basis of many coastal marine food webs. An increase in algal biomass results in increased primary productivity, which translates into a higher abundance of primary and secondary consumers. It is well documented that rocky reefs provide important habitat for many commercially harvested species, including salmon, rockfish, lingcod, herring, Dungeness crab and red rock crab. For the purposes of this assessment, it is assumed that compensation/offset measures will include the construction of a subtidal rock reef near the Westridge Marine Terminal; however, the this option may or may not be included in the final compensation/offset plan depending on feedback from DFO, Aboriginal communities and other interested stakeholders.

With the implementation of marine fish habitat compensation/offset measures, there will be no net loss of productive capacity of marine fish habitat. Compared to the existing riparian vegetation, which has a limited value to marine fish, the subtidal rock reef will provide direct benefits to a variety of harvested species, including rockfish, salmon and Dungeness crab. The temporary decrease in productive capacity that occurs during the time it takes for the rock reef to become fully functional habitat (anticipated 2 to 3 years) will be completely offset by the creation of high value habitat that will persist in perpetuity. As a result, the effect of loss of marine riparian habitat is considered to be of low magnitude (Table 7.6.9-3, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – the physical effects to marine riparian habitat will be limited to the area of overlap between marine riparian habitat and the Footprint.
- Duration: short-term – the activities and works causing the loss of marine riparian habitat will occur during construction activities on the foreshore, which is expected to take no more than 2 years.
- Frequency: isolated – the events causing the loss of marine riparian habitat will be limited to the construction phase.
- Reversibility: permanent – loss of marine riparian habitat will be permanent.

- Magnitude: low – with the implementation of a marine fish habitat compensation/offset program, there will be no net loss of productive capacity of marine fish habitat.
- Probability: high – riparian clearing will be required for construction of the expanded Westridge Marine Terminal.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationship between construction of the Westridge Marine Terminal and the loss of marine riparian habitat, and the effectiveness of the marine fish habitat compensation/offset program.

Marine Fish and Fish Habitat Indicator – Intertidal Habitat

The following subsection provides the evaluation of significance of the potential residual effect on the intertidal habitat indicator.

Loss of Intertidal Habitat Due to Construction Activities

Intertidal habitat is present along the entire length of shoreline within the Marine Fish and Fish Habitat LSA. Based on information from BC MFLNRO (2005), three shore types are present within the Marine Fish and Fish Habitat LSA including ‘man-made’, ‘mud flat’, and ‘sand flat’. Man-made is the dominant shore type, covering approximately 1 km or 44% of the shoreline in the Marine Fish and Fish Habitat LSA (BC MFLNRO 2005). The Footprint of the in-water construction activities overlaps with the man-made shore type. Updated and extensively more detailed information on shoreline type and character within the Marine Fish and Fish Habitat LSA and all the Central Harbour of Burrard Inlet, will be available in the first quarter of 2014. This is currently being completed as a separate Trans Mountain initiative, which is developing a pre-spill SCAT database for the purpose of enhancing emergency preparedness and response capability within this area of Burrard Inlet. For additional information please refer to Volume 8C.

Intertidal habitat features and biological assemblages in the Marine Fish and Fish Habitat LSA were observed during the intertidal survey conducted at the Westridge Marine Terminal on August 18-19, 2012 (see Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C). Intertidal habitat within the Marine Fish and Fish Habitat LSA is characterized by steep, boulder and cobble rip rap substrate with small areas of gravel and sand. A total of 17 marine invertebrate species and 8 marine algae species were observed in the intertidal zone.

The expansion and upgrade of the Westridge Marine Terminal will include the construction of three new tanker berths, a new utility dock, and an extension of the foreshore adjacent to the berths. The foreshore extension will effectively move the intertidal zone seaward of its current location, and the zone is expected to retain the same general physical characteristics (*i.e.,* steep, boulder and cobble rip rap). Approximately 5,470 m^2 of intertidal habitat will be lost due to infilling, and this is considered to have a negative impact balance. However, this loss will be partially offset by the creation of approximately 3,770 m^2 of new rocky intertidal habitat (rip rap) along the outer face of the fill area.

While the loss of intertidal habitat will be permanent, there will be no net loss of the productive capacity of marine fish habitat in the Marine Fish and Fish Habitat LSA. High-value marine fish habitat will be created through the marine fish habitat compensation/offset program. As currently envisaged, the habitat compensation program would involve the construction of a subtidal rock reef near the Westridge Marine Terminal. Within 2 to 3 years, a diverse community of algae, invertebrates, and fish are expected become established on the rock reef, as well as on the rip rap placed in the intertidal zone. As a result, there will be no net loss of productive capacity of marine fish habitat in the Marine Fish and Fish Habitat LSA and this effect is considered to be of low magnitude (Table 7.6.9-3, point 2[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – the physical effects to intertidal habitat will be limited to the area of overlap between intertidal habitat and the Footprint.
- Duration: short-term – the activities and works causing the loss of intertidal habitat will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.

- Frequency: isolated – the events causing the loss of intertidal habitat will be limited to the construction phase.
- Reversibility: permanent – loss of intertidal habitat will be permanent.
- Magnitude: low – with the implementation of a marine fish habitat compensation/offset program, there will be no net loss of productive capacity of marine fish habitat.
- Probability: high – the proposed in-water construction activities are likely to result in the loss of intertidal habitat.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationship between construction of the Westridge Marine Terminal and the loss of intertidal habitat, and the effectiveness of the marine fish habitat compensation/offset program.

Marine Fish and Fish Habitat Indicator – Subtidal Habitat

The following subsection provides the evaluation of significance of the potential residual effect on the marine subtidal habitat indicator.

Loss of Subtidal Habitat Due to Construction Activities

Subtidal habitat is present throughout the Marine Fish and Fish Habitat LSA below the mean lower low water level. The inner portions of Burrard Inlet are predominantly shallow (<30 m) mud substrates (BC Marine Conservation Analysis 2009, Burd *et al.* 2008, Burd 1990). Subtidal habitat features and biological assemblages in the Marine Fish and Fish Habitat LSA were observed during the subtidal remotely operated vehicle (ROV) survey conducted at the Westridge Marine Terminal on September 17-20, 2012 (see Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C). Subtidal habitat within the Marine Fish and Fish Habitat LSA is characterized by soft substrates (silt, mud, sand) with traces of broken shells and wood debris. A total of 32 species of marine fauna were observed during the subtidal ROV survey including 8 species of arthropods, 7 species of echinoderms, 9 species of fish, 4 species of cnidarians, 3 species of molluscs, and 1 species of tunicate. Algal diversity and density was low.

The expansion and upgrade of the Westridge Marine Terminal will include the construction of three new tanker berths, a new utility dock, and an extension of the foreshore adjacent to the new berths. The foreshore extension will involve infilling areas of subtidal habitat and the construction of the new berths and connecting trestles will involve the placement of piles in subtidal habitat. The total area of subtidal habitat lost to infill and pile placement is approximately 17,100 m^2, and this is considered to have a negative impact balance. However, this loss will be partially offset by the creation of approximately 5,550 m^2 of new rocky subtidal habitat (rip rap) along the outer face of the fill area.

While the loss of subtidal habitat will be permanent, there will be no net loss of productive capacity of marine fish habitat in the Marine Fish and Fish Habitat LSA. High-value marine fish habitat will be created through the marine fish habitat compensation/offset program. As currently envisaged, the program will involve the construction of a subtidal rock reef near the Westridge Marine Terminal. Within 2 to 3 years, a diverse community of algae, invertebrates, and fish are expected to become established on the rock reef, as well as on the rip rap placed in the subtidal zone. As a result, there will be no net loss of productive capacity of marine fish habitat in the Marine Fish and Fish Habitat LSA and this effect is considered to be of low magnitude (Table 7.6.9-3, point 3[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – the physical effects to subtidal habitat will be limited to the area of overlap between subtidal habitat and the Footprint.
- Duration: short-term – the activities and works causing the loss of subtidal habitat will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events causing the loss of subtidal habitat will be limited to the construction phase.

- Reversibility: permanent – loss of subtidal habitat will be permanent.
- Magnitude: low – with the implementation of a marine fish habitat compensation/offset program, there will be no net loss of productive capacity of marine fish habitat.
- Probability: high – the proposed in-water construction activities are likely to result in the loss of subtidal habitat.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationships between construction of the Westridge Marine Terminal and the loss of subtidal habitat, and the effectiveness of the marine fish habitat compensation/offset program.

Marine Fish and Fish Habitat Indicator – Dungeness Crab

The following subsections provide the evaluation of significance of potential residual effects on the Dungeness crab indicator.

Decrease in Productive Capacity of Suitable Habitat for Dungeness Crab

Dungeness crabs typically inhabit sand, mud, or silt substrates and eelgrass beds from the low intertidal zone to depths of 230 m (DFO 2013d). Dungeness crabs were observed in relatively high abundance during the subtidal ROV survey conducted at the Westridge Marine Terminal on September 17-20, 2012 (see Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C). All crabs were observed on soft sediment habitats which was the dominant substrate type observed within the Marine Fish and Fish Habitat LSA. Although no Dungeness crabs were observed during the intertidal survey conducted on August 18-19, 2012 (see Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C), sub-adults and larvae are known to occur in nearshore habitats in inlet environments and are presumed to use the intertidal habitats present within the Marine Fish and Fish Habitat LSA (DFO 2013d, McConnaughey *et al.* 1992).

The loss of intertidal and subtidal habitats (see effects assessments above) is likely to result in a temporary decrease in the productive capacity of Dungeness crab habitat within the Marine Fish and Fish Habitat LSA, which is considered to have a negative impact balance. Although the physical effects to intertidal and subtidal habitats will be limited to the Footprint, the productive capacity of surrounding habitats may be affected as a result of decreased productivity (*e.g.,* algal biomass) and decreased prey availability. This effect will be reversible in the medium-term through the creation of marine compensation/offset habitat and through the natural establishment of algae and invertebrates on the rocky habitats created as a result of infilling (*i.e.,* intertidal and subtidal rip rap). As currently envisaged, the marine fish habitat compensation/offset program will involve the construction of a of rock reef in the subtidal zone near the Westridge Marine Terminal. This reef will provide rearing habitat for recently-settled Dungeness crab larvae and foraging habitat for sub-adult and adult crabs. Algae, invertebrates, and fish are expected to become established on the rock reef and the intertidal and subtidal rip rap within a period of 2 to 3 years after their construction, providing rearing and foraging habitat for Dungeness crabs. With this mitigation, there will be no net loss of the productive capacity of Dungeness crab habitat due to Project-related construction activities in the Marine Fish and Fish Habitat LSA. As a result, this effect is considered to be low magnitude (Table 7.6.9-3, point [4a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Fish and Fish Habitat LSA – although the physical effects to intertidal and subtidal habitats will be limited to the Footprint, the productive capacity of surrounding habitats may be affected as a result of decreased productivity (*e.g.,* algal biomass) and decreased prey availability.
- Duration: short-term – the events causing the loss of productive capacity will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events causing the loss of productive capacity will be limited to the construction phase.

- Reversibility: medium-term – it is expected to take 2 to 3 years for a fully functional biotic community to become established on the subtidal rock reef (marine compensation/offset habitat) and the intertidal and subtidal rip rap habitat.
- Magnitude: low – with the implementation of a marine fish habitat compensation/offset program, there will be no net loss of the productive capacity of Dungeness crab habitat.
- Probability: high – the proposed in-water construction activities are likely to result in the loss of marine fish habitat and subsequently a loss of productive capacity of suitable Dungeness crab habitat.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationships between construction of the Westridge Marine Terminal and the productive capacity of marine fish habitat, and the effectiveness of the marine fish habitat compensation/offset program.

Injury or Mortality to Dungeness Crab Due to Burial or Crushing During Infilling and Dredging

Infilling of nearshore habitats will result in the direct mortality of some intertidal and subtidal organisms, primarily through burial and crushing. Sessile organisms (*e.g.,* barnacles, mussels, limpets) will be most susceptible to harm, whereas mobile species (*e.g.,* crabs, rockfish, salmon) will generally be able to avoid harm by dispersing from the work area. The installation of steel pipe piles may also result in the mortality of some sessile subtidal organisms, although the physical footprint of all 220 piles combined is expected to be only 400 m^2. Dredging, if required, will likely be performed using a clamshell bucket, which takes large scoops of sediment from the seafloor and deposits them on a barge. Benthic invertebrates living within the dredge area will be physically removed from the ocean, and will die due to crushing and/or desiccation.

Given the abundance of Dungeness crab within the Footprint, it is likely that some individuals will be harmed or killed during infilling and dredging, and this is considered to have a negative impact balance. To minimize the number of individuals affected, a crab salvage program will be conducted prior to the commencement of both infilling and dredging. Baited traps will be deployed within and adjacent to the work area, and crabs will be relocated to suitable habitat outside of the Marine Fish and Fish Habitat LSA. Because crab traps are selective for larger individuals, it will not be possible to recover sub-adult crabs. However, Dungeness crab are abundant throughout Burrard Inlet (Jamieson and Levesque 2012a,b), the loss of a small number of individuals will not affect the viability of the local population. To further mitigate potential injury or mortality to Dungeness crabs, marine infilling and dredging activities will be restricted to the DFO least-risk timing window for Burrard Inlet, which is from August 16 to February 28. If this becomes impractical, timing will be determined in consultation with DFO.

With the application of mitigation measures, injury or mortality to Dungeness crab due to burial or crushing during infilling and dredging is considered to be low magnitude (Table 7.6.9-3, point [4b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – direct physical effects to Dungeness crab will be limited to the area of infill and the dredge footprint.
- Duration: short-term – the events causing injury or mortality to Dungeness crab will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events causing injury or mortality of Dungeness crab will be limited to the construction phase.
- Reversibility: medium-term – Dungeness crab spawn annually and are expected to return to pre-disturbance abundance within 1 to 2 years post-construction.
- Magnitude: low – based on the abundance of Dungeness crab in the Marine Fish and Fish Habitat LSA and Marine RSA, the availability of suitable habitat, and the limited spatial extent of infilling and dredging.
- Probability: high – infilling and dredging are likely to result in the loss of a relatively small number of Dungeness crabs.

- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationships between construction of the Westridge Marine Terminal and injury or mortality to Dungeness crab, and the effectiveness of the proposed mitigation.

Combined Effects on Dungeness Crab

Construction of the Westridge Marine Terminal is expected to result in a temporary loss of the productive capacity of suitable Dungeness crab habitat within the Marine Fish and Fish Habitat LSA and the injury or mortality of a relatively small number of individuals within the Footprint. The combined effects on Dungeness crab are considered to have a negative impact balance. However, these effects will be limited in spatial extent and are considered to be reversible in the medium-term. With the implementation of a marine fish habitat compensation/offset program and the establishment of algae, invertebrates, and fish on the intertidal and subtidal rip rap habitat, there will be no net loss of the productive capacity of suitable Dungeness crab habitat.

Dredging and infilling associated with construction of the Westridge Marine Terminal are expected to result in injury or mortality to Dungeness crab. The crab salvage program will greatly reduce the number of adult crabs potentially harmed or killed as a result of in-water construction activities. Given the abundance of this species in Burrard Inlet, the loss of a small number of individuals (mostly juveniles) will not affect the viability of the local population. As a result, the combined effects on Dungeness crab are expected to be of low magnitude (Table 7.6.9-3, point 4[c]). A summary of the rationale for all of the significance criteria of combined effects on Dungeness crab is provided below.

- Spatial Boundary: Marine Fish and Fish Habitat LSA – combined effects on Dungeness crab will be focused within the Footprint, but are expected to extend into the LSA.
- Duration: short-term – the events causing combined effects on Dungeness crab will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events causing combined effects on Dungeness crab will be limited to the construction phase.
- Reversibility: medium-term – combined effects on Dungeness crab are expected to take two to three years to reverse.
- Magnitude: low – based on the abundance of Dungeness crab in the Marine Fish and Fish Habitat LSA and Marine RSA, the availability of suitable habitat, and the limited spatial extent of potential Project effects.
- Probability: high – combined effects on Dungeness crab are likely to occur as a result of construction of the Westridge Marine Terminal.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationships between construction activities (*i.e.,* dredging and infilling) and Dungeness crab, and the effectiveness of the proposed mitigation measures.

Marine Fish and Fish Habitat Indicator – Inshore Rockfish

The following subsections provide the evaluation of significance of potential residual effects on the inshore rockfish indicator.

Decrease in Productive Capacity of Suitable Habitat for Inshore Rockfish

Inshore rockfish such as quillback and copper rockfish typically inhabit rock reefs in relatively shallow water inlets (DFO 2001, Hart 1973, Yamanaka and Lacko 2001). Pelagic larvae develop into juveniles, who then settle in rock reef areas where they typically demonstrate high site fidelity, rarely moving from the area (DFO 2001, Love *et al.* 2002). Rockfish were not observed during the subtidal ROV survey conducted at the Westridge Marine Terminal on September 17-20, 2012 (see Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C) and the survey revealed that the seabed of the Marine Fish and Fish Habitat LSA consists almost entirely of soft substrates (*i.e.,* silt, mud, sand) with some small areas of rock substrate. Rock rip rap is present in the intertidal and shallow subtidal zones adjacent to the Westridge Marine Terminal. Although rockfish were not observed during the subtidal ROV survey and the predominantly soft substrates in the subtidal zone are not ideal habitat for inshore rockfish, subtidal and intertidal rock substrates and rock rip rap may provide suitable habitat for inshore rockfish and they are presumed to be present in low abundance within the Marine Fish and Fish Habitat LSA.

The loss of intertidal and subtidal habitats (see effects assessments above) is likely to result in a temporary decrease in the productive capacity of rockfish habitat within the Marine Fish and Fish Habitat LSA. Although the physical effects to intertidal and subtidal habitats will be limited to the Footprint, the productive capacity of surrounding habitats may be affected as a result of decreased productivity (*e.g.,* algal biomass) and decreased prey availability. This effect will be reversible in the medium-term through the creation of marine compensation/offset habitat and through the natural establishment of algae and invertebrates on the intertidal and subtidal rip rap habitat created as a result of infilling. As currently envisaged, the marine fish habitat compensation/offset program would involve the construction of a rock reef in the subtidal zone near the Westridge Marine Terminal. This reef will provide more suitable habitat for juvenile and adult rockfish than the soft substrates that currently dominate the Marine Fish and Fish Habitat LSA, and will support rockfish populations in the Eastern Burrard Inlet RCA. Algae, invertebrates, and fish are expected to become established on the rock reef and the intertidal and subtidal rip rap within a period of 2 to 3 years after their construction, providing foraging and spawning habitat for juvenile and adult rockfish. With this mitigation, there will be no net loss of the productive capacity of suitable inshore rockfish habitat due to Project-related construction activities in the Marine Fish and Fish Habitat LSA. As a result, this effect is considered to be of low magnitude (Table 7.6.9-3, point 5[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Fish and Fish Habitat LSA – although the physical effects to intertidal and subtidal habitats will be limited to the Footprint, the productive capacity of surrounding habitats may be affected as a result of decreased productivity (*e.g.,* algal biomass) and decreased prey availability.
- Duration: short-term – the events causing the loss of productive capacity will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events causing the loss of productive capacity will be limited to the construction phase.
- Reversibility: medium-term – it is expected to take 2 to 3 years for a fully functional biotic community to become established on the subtidal rock reef (marine compensation/offset habitat) and the intertidal and subtidal rip rap habitat.
- Magnitude: low – with the implementation of a marine fish habitat compensation/offset program, there will be no net loss of the productive capacity of suitable rockfish habitat.
- Probability: high – the proposed in-water construction activities are likely to result in the loss of marine fish habitat and subsequently a loss of productive capacity of suitable inshore rockfish habitat.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationships between Terminal construction and the productive capacity of marine fish habitat, and the effectiveness of the proposed marine fish habitat compensation/offset program.

Injury or Mortality to Inshore Rockfish Due to Burial or Crushing During Infilling and Dredging

Given the potential for inshore rockfish to be present at low abundance within the Footprint, it is possible that a small number of individuals will be harmed or killed during infilling and dredging, and this is considered to have a negative impact balance. However, the subtidal ROV survey conducted within the Marine Fish and Fish Habitat LSA indicated that the majority of habitat is soft sediment, which has relatively low value for inshore rockfish. Only a small area of complex rocky habitat will be affected by Project construction, and this is a submerged rip rap embankment that was created during historical infilling at the site. During construction, any rockfish that are present within the Footprint may avoid harm by moving away from the work area to adjacent undisturbed habitats. To mitigate potential harm to inshore rockfish, marine infilling and dredging activities will be restricted to the DFO least-risk work window for Burrard Inlet, which is from August 16 to February 28. If this becomes impractical, timing will be determined in consultation with DFO.

Although several species of inshore rockfish have experienced substantial population declines in recent decades as a result of overfishing (Yamanaka and Logan 2010), nearshore species such as the copper rockfish, which is the most likely species to occur in the shallow waters of the Marine Fish and Fish Habitat LSA, are relatively common throughout shallow inlets in the Strait of Georgia (COSEWIC 2009, Hart 1973, Love *et al.* 2002) and the loss of a small number of individuals will not affect the viability of the local populations. In addition, the construction of a rock reef in the subtidal zone near the Westridge Marine Terminal as part of the marine fish habitat compensation/offset program will provide more suitable habitat for juvenile and adult rockfish than the soft substrates that currently dominate the Marine Fish and Fish Habitat LSA, and is expected to increase the abundance of inshore rockfish within the Eastern Burrard Inlet RCA. As a result, injury or mortality to inshore rockfish due to burial or crushing during infilling and dredging is considered to be low magnitude (Table 7.6.9-3, point 5[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – direct physical effects to rockfish will be limited to the area of infill and the dredge footprint.
- Duration: short-term - the events causing injury or mortality to rockfish will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated - the events causing injury or mortality rockfish will be limited to the construction phase.
- Reversibility: medium-term – in the unlikely event that a small number of inshore rockfish are killed during Project construction, it may take one to two generations (copper rockfish generation time is approximately 7 years; Love *et al.* 2002) for abundance to return to pre-disturbance levels.
- Magnitude: low – based on the low abundance of rockfish in the Marine Fish and Fish Habitat LSA and Marine RSA, the lack of high-value habitat, and the limited spatial extent of infilling and dredging.
- Probability: low – infilling and dredging are unlikely to result in injury or mortality to rockfish due to their ability to avoid disturbances by temporarily avoiding the work area and the low abundance of rockfish in the Marine Fish and Fish Habitat LSA.
- Confidence: high - based on a good understanding by the assessment team of the cause-effect relationships between construction of the Westridge Marine Terminal and injury or mortality to rockfish, and the effectiveness of the proposed mitigation.

Injury or Mortality to Inshore Rockfish Due to Underwater Noise Produced During Pile Driving

Construction of the marine loading berths will involve the installation of large diameter steel piles (*i.e.,* pile driving). Pile driving can result in the generation of high energy pressure waves that radiate outward from the sound source. If these pressure waves are of sufficient magnitude, they can result in physical injury to fish as they pass through a fish's swim bladder. The interim criteria recommended to evaluate potential harm from pile driving are a peak sound pressure level (peak SPL) of 208 dB re: 1µPa per single strike and an accumulated sound exposure level (SEL) of 187 dB re: 1µPa^2-sec (Popper *et al.* 2006). Peak SPL determines whether the swim bladder and ear are subjected to extreme mechanical stress whereas SEL describes the potential for damage from different wave lengths and energy distributions.

The intensity of sound levels that are produced during pile driving depends on a variety of factors. These typically include the following:

- method of installation (*e.g.,* vibratory or impact hammer);
- type of pile (*e.g.,* steel, concrete, or wood);
- diameter of the pile;

- size of the hammer;
- sediment type and geotechnical conditions;
- tidal and current conditions (particularly if sound attenuation systems such as non-enclosed bubble curtains are used); and
- water depth (Illingworth and Rodkin Inc. 2007).

The exact engineering details concerning the sizes and number of piles or method of installation that will be used for construction of the Westridge Marine Terminal were not known at the time of this assessment. However, noise levels produced during in-water pile installation have been recorded during past construction projects, and are available in the literature (*e.g.,* Illingworth and Rodkin Inc. 2007). SPLs (peak and root mean square [RMS]) and SELs recorded for the installation of large diameter piles of varying sizes and materials are available for both vibratory driver and impact hammer methods and some examples are provided in Table 7.6.9-5. The effects assessment has been developed based on the assumption that 220 1.4 m (1,371.6 mm [NPS 54]) vertical steel pipe piles will be installed intermittently, using an impact hammer, over the course of approximately 2 years. Therefore, the literature values presented for the 1.5 m (1,498.6 mm [NPS 59]) steel CISS (cast-in-steel shell) pile were used as surrogate source levels to assess the potential acoustic effects of pile driving.

TABLE 7.6.9-5

EXAMPLE UNMITIGATED UNDERWATER SOUND LEVELS FROM VARIOUS PILE DRIVING SOURCES

Pile Type and Size	Peak SPL (dB_{peak} re: 1µPa)	SEL (dB re: 1 $µPa^2$-s)	RMS SPL (dB_{rms} re: 1 µPa)
Impact Hammer Installation Method			
2.4 m steel CISS	220	195	205
1.5 m steel CISS	210	185	195
0.91 m steel pipe pile	210	183	193
0.61 m steel pipe pile	207	178	194
0.61 m concrete pile	188	166	176
Vibratory Driver/Extractor Installation Method			
1.8 m steel pipe pile (loudest)	195	180	180
1.8 m steel pipe pile (typical)	183	170	170
0.91 m steel pipe pile	185	175	175
0.61 m AZ steel sheet	182	165	165

Source: Sample values taken from Tables 1.2-1 and 1.2-2 of Illingworth and Rodkin Inc. 2007.

Notes: SPL = Sound Pressure Level; SEL = Sound Exposure Level; RMS = Root Mean Square; CISS = cast-in-steel shell. Sound levels provided above are for illustrative purposes only; sound levels may be highly variable from one situation to another. All sound levels were measured at 10 m from the pile. Depths varied and are presented in Illingworth and Rodkin Inc. 2007 along with further details concerning measurements and sources. Decibels re: 1 µPa are the accepted unit for measuring underwater sound as it relates to marine wildlife (Richardson *et al.* 1995, Southall *et al.* 2007), however, there are different metrics (*i.e.,* peak vs RMS) for calculating and reporting decibels. SELs are a measure of received sound energy and values presented in Table 7.6.9-5 are not M-weighted by any functional hearing groups as in Southall *et al.* 2007; however, generalized comparison to the Southall *et al.* 2007 thresholds (Table 7.6.11-2) is believed to be conservative.

Construction of the marine loading berths may require a small amount of dredging. Dredging typically produces underwater noise of lower sound levels than pile driving. A typical suction cutter dredge has a broadband source level (peak SPL) of 187 dB re: 1 µPa at 1 m, while a typical clamshell dredge has a maximum broadband source level of ~167 dB re: 1 µPa at 1 m (Richardson *et al.* 1995). The dock layout of the proposed Westridge Marine Terminal expansion was designed to reduce or eliminate the need for dredging, so it is most likely that none will be required; however, for the purposes of this assessment, the potential for a small amount of dredging over the course of the two-year construction period has been assessed. Specifications concerning which dredging equipment would be used for construction of the Westridge Marine Terminal were not known at the time of this assessment. For the purpose of the assessment, it was assumed that a small amount of dredging will be required (*i.e.,* approximately 60 days) and that this will be conducted using a clamshell dredge. Sound levels produced by the clamshell dredge are not expected to exceed those produced during pile driving activities and both of the example literature levels noted above are below the peak SPL criterion for injury to fish (208 dB re: 1µPa; Popper *et al.* 2006).

To reduce the likelihood of injury or mortality to rockfish due to exposure to sound from pile-driving, Trans Mountain will use a vibratory method of pile installation wherever technically feasible. Vibratory pile installation typically generates noise levels approximately 25 dB below those generated by impact pile installation, and does not produce the high impulse signatures of impact pile driving (McCauley and Salgado Kent 2008). If an impact or hydraulic hammer is required for pile installation, Trans Mountain will implement several mitigation measures when driving the piles. These recommendations are in concordance with the *Best Management Practices for Pile Driving and Related Operations* developed by the BC Marine and Pile Driving Contractors Association for driving steel pipe piles with a diameter greater than 609.6 mm (NPS 24). First, bubble curtains will be deployed over the full length of the wetted pile. The bubbles act as a barrier and reduce the propagation of shock waves through the water from pile-driving. Second, a hydrophone will be used to monitor the pressure levels from pile-driving. Should the sound pressure exceed 30 kPa, the work will stop immediately and the methods will be reviewed and corrected to ensure acceptable conditions.

With the mitigation measures described above, underwater noise levels produced during pile installation will not exceed the peak SPL criterion for injury to fish (208 dB re: 1µPa; Popper *et al.* 2006), except possibly within the immediate vicinity (*i.e.*, several metres) of the pile. Any rockfish within this range are expected to relocate in response to preparatory activities such as pile placement and/or installation of bubble curtains. Though unlikely, it is possible that a small number of rockfish could be harmed or killed due to underwater noise produced during pile driving; therefore, this residual effect is considered to have a negative impact balance. However, the proposed mitigation measures are expected to be effective at minimizing or eliminating potential harm to inshore rockfish. As a result, injury or mortality to inshore rockfish due to underwater noise produced during pile driving is considered to be low magnitude (Table 7.6.9-3, point 5[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Fish and Fish Habitat LSA – although pile-driving activities will be limited to the Footprint, underwater sound generated by pile-driving is expected to propagate throughout the LSA.
- Duration: short-term – the events potentially causing injury or mortality to rockfish will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events potentially causing injury or mortality to rockfish will be limited to the construction phase.
- Reversibility: medium-term – in the unlikely event that a small number of inshore rockfish are killed during Project construction, it may take one to two generations (copper rockfish generation time is approximately 7 years; Love *et al.* 2002) for abundance to return to pre-disturbance levels.
- Magnitude: low – based on the low abundance of rockfish in the Marine Fish and Fish Habitat LSA and Marine RSA and the effectiveness of the proposed mitigation.
- Probability: low – injury or mortality to rockfish is unlikely due to their low abundance within the Marine Fish and Fish Habitat LSA and the effectiveness of the proposed mitigation.
- Confidence: high – based on a reasonable understanding by the assessment team of the cause-effect relationships between underwater noise levels produced during pile-driving and injury or mortality to rockfish, and a good understanding of the effectiveness of the proposed mitigation.

Marine Fish and Fish Habitat Indicator – Pacific Salmon

The following subsections provide the evaluation of significance of potential residual effects on the Pacific salmon indicator.

Decrease in Productive Capacity of Suitable Habitat for Pacific Salmon Due to Construction Activities

Burrard Inlet has been identified as a DFO Important Area for Pacific salmon (Jamieson and Levesque 2012a,b) and the area provides suitable habitat for salmon during different phases of their life cycle. Pacific salmon migrate through Burrard Inlet on their way to and from spawning rivers and streams, and juvenile salmon spend time rearing and foraging in estuaries and inshore habitats before migrating offshore (DFO 2001, Hart 1973). Although Pacific salmon were not observed during the subtidal ROV survey conducted at the Westridge Marine Terminal from September 17 to 20, 2012 (see Marine Resources – Westridge Marine Terminal Technical Report of Volume 5C), salmon are presumed to be present within the Marine Fish and Fish Habitat LSA at times.

The loss of intertidal and subtidal habitats (see effects assessments above for these indicators) is likely to result in a temporary decrease in the productive capacity of Pacific salmon habitat within the Marine Fish and Fish Habitat LSA, and this is considered to have a negative impact balance. Although the physical effects to intertidal and subtidal habitats will be limited to the Footprint, the productive capacity of surrounding habitats may be affected as a result of decreased productivity (*e.g.,* algal biomass) and decreased prey availability. This effect will be reversible in the medium-term through the creation of marine compensation/offset habitat and through the natural establishment of algae and invertebrates on the intertidal and subtidal rip rap created as a result of infilling. As currently envisaged, the marine fish habitat compensation/offset program would involve the construction of a rock reef in the subtidal zone near the Westridge Marine Terminal. Algae, invertebrates, and fish are expected to become established on the rock reef and the intertidal and subtidal rip rap within a period of 2 to 3 years after their construction, providing rearing and foraging habitat for Pacific salmon.

Underwater noise produced during in-water construction activities (*e.g.*, dredging and pile installation) may cause Pacific salmon to temporarily avoid the work area, resulting in a temporary decrease in the productive capacity of habitats within the Marine Fish and Fish Habitat LSA. Although no explicit behavioural thresholds exist for fish, studies have shown that some species of fish, including salmonids, exhibit startle and avoidance responses to underwater sound (McCauley *et al.* 2000, Nedwell *et al.* 2006, Wardle *et al*. 2001). Because salmon are hearing generalists and, therefore, assumed to be relatively insensitive to underwater noise, behavioural responses are expected to be limited in spatial extent, short-lived, and unlikely to affect feeding ability (Nedwell *et al.* 2006). Shoreline habitat within the Marine Fish and Fish Habitat LSA is primarily anthropogenic and lacks structural complexity. While juvenile salmon likely use this area to some extent for rearing and foraging, it does not possess the habitat attributes that would make it high value nursery habitat for juvenile salmon (*e.g.*, kelp, eelgrass, undulating shoreline, embayments, natural substrate). While localized avoidance of nearshore habitats within the Marine Fish and Fish Habitat LSA by salmon during periods of in-water construction will decrease the productive capacity of this habitat, the effect will be temporary and is not expected to affect the viability of any local populations.

With the implementation of compensation/offset measures, there will be no net loss of productive capacity of suitable habitat for Pacific salmon within the Marine Fish and Fish Habitat LSA. As a result, this effect is considered to be low magnitude (Table 7.6.9-3, point 6[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Fish and Fish Habitat LSA – although the physical effects to intertidal and subtidal habitats will be limited to the Footprint, the productive capacity of surrounding habitats may be affected as a result of decreased productivity (*e.g.,* algal biomass) and decreased prey availability; underwater noise produced during in-water construction activities may result in temporary behavioural responses within the Marine Fish and Fish Habitat LSA, decreasing the productive capacity of available habitat

- Duration: short-term – the events causing the loss of productive capacity will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.

- Frequency: isolated – the events causing the loss of productive capacity will be limited to the construction phase.

- Reversibility: medium-term – any behavioural changes induced by underwater noise are expected to be immediately reversible upon the cessation of in-water construction; it is expected to take two to three years for a fully functional biotic community to become established on the subtidal rock reef (marine compensation/offset habitat) and the intertidal and subtidal rip rap habitat.
- Magnitude: low – with the implementation of a marine fish habitat compensation program, there will be no net loss of the productive capacity of suitable Pacific salmon habitat.
- Probability: high – the proposed in-water construction activities are likely to result in the loss of marine fish habitat and, subsequently, a loss of productive capacity of suitable Pacific salmon habitat; underwater noise produced during in-water construction activities is likely to result in short-term behavioural responses including localized avoidance of the construction area.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationships between construction of the Westridge Marine Terminal and the productive capacity of marine fish habitat, and the effectiveness of the marine fish habitat compensation/offset program.

Injury or Mortality to Pacific Salmon Due to Burial or Crushing During Infilling and Dredging

Given the potential for Pacific salmon to be present within the Footprint, it is possible that a small number of individuals will be harmed or killed during infilling and dredging; therefore, this residual effect is considered to have a negative impact balance. To minimize potential harm to Pacific salmon, marine infilling and dredging activities will be restricted to the DFO least-risk work window for Burrard Inlet, which is from August 16 to February 28. This will avoid the times when juvenile and adult salmon are most abundant in Burrard Inlet (late spring to summer). If this becomes impractical, timing will be determined in consultation with DFO. Pacific salmon are relatively abundant in Burrard Inlet and the Strait of Georgia (DFO 2013e) and the loss of a small number of individuals will not affect the viability of the local populations. As a result, injury or mortality to Pacific salmon due to burial or crushing during infilling and dredging is considered to be low magnitude (Table 7.6.9-3, point [6b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – direct physical effects to Pacific salmon will be limited to the area of infill and the dredge footprint.
- Duration: short-term – the events potentially causing injury or mortality to Pacific salmon will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events potentially causing injury or mortality to Pacific salmon will be limited to the construction phase.
- Reversibility: medium-term – with the exception of pink salmon which spawn in odd-years in Burrard Inlet, Pacific salmon spawn annually; therefore, in the unlikely event that a small number of Pacific salmon are killed during Project construction, abundance is expected to return to pre-disturbance levels within one to two years post-construction.
- Magnitude: low – based on the predicted low abundance of Pacific salmon in the Marine Fish and Fish Habitat LSA and Marine RSA, the lack of high-value Pacific salmon habitat, the timing of infilling and dredging (DFO least-risk window) and the limited spatial extent of infilling and dredging.
- Probability: low – infilling and dredging are unlikely to result in injury or mortality to Pacific salmon due to their ability to avoid harm by dispersing from the work area, and the timing of infilling and dredging to avoid periods of high salmon abundance.
- Confidence: high – based on a good understanding by the assessment team of the cause-effect relationships between construction of the Westridge Marine Terminal and injury or mortality to Pacific salmon and the effectiveness of the proposed mitigation.

Injury or Mortality to Pacific Salmon Due to Underwater Noise Produced During Pile Driving

The effects of underwater noise from pile-driving on marine fish are described above under *Injury or Mortality to Inshore Rockfish Due to Underwater Noise Produced During Pile Driving*. Potential effects on Pacific salmon are expected to be similar to those described for inshore rockfish.

To reduce the likelihood of injury or mortality to Pacific salmon due to exposure to sound from pile-driving, Trans Mountain will use a vibratory method of pile installation wherever technically feasible. If an impact or hydraulic hammer is required for pile installation, Trans Mountain will implement several mitigation measures when driving the piles, as previously discussed under the inshore rockfish indicator. This includes the installation of bubble curtains around the full wetted length of the pile and monitoring of underwater noise levels with a hydrophone to ensure they do not exceed 30 kPa, as recommended in the *Best Management Practices for Pile Driving and Related Operations*.

With the mitigation measures described above, underwater noise levels produced during pile installation will not exceed the peak SPL criterion for injury to fish (208 dB re: 1µPa; Popper *et al.* 2006), except possibly within the immediate vicinity (*i.e.*, several metres) of the pile. Any salmon within this range are expected to relocate in response to preparatory activities such as pile placement and/or installation of bubble curtains. Though unlikely, it is possible that a small number of salmon could be harmed or killed due to underwater noise produced during pile driving; therefore, this residual effect is considered to have a negative impact balance. However, the proposed mitigation measures are expected to be effective at minimizing or eliminating potential harm to Pacific salmon. As a result, injury or mortality to Pacific salmon due to underwater noise produced during pile driving is considered to be low magnitude (Table 7.6.9-3, point 6[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Fish and Fish Habitat LSA – although pile-driving activities will be limited to the Footprint, underwater sound generated by pile-driving is expected to propagate throughout the Marine Fish and Fish Habitat LSA.
- Duration: short-term – the events potentially causing injury or mortality to Pacific salmon will occur during the construction of in-water infrastructure, which is expected to take no more than 2 years.
- Frequency: isolated – the events potentially causing injury or mortality to Pacific salmon will be limited to the construction phase.
- Reversibility: medium-term – with the exception of pink salmon which spawn in odd-years in Burrard Inlet, Pacific salmon spawn annually; therefore, in the unlikely event that a small number of Pacific salmon are killed during Project construction, abundance is expected to return to pre-disturbance levels within one to two years post-construction.
- Magnitude: low – based on the abundance of Pacific salmon in the Marine Fish and Fish Habitat LSA and Marine RSA and the effectiveness of the proposed mitigation.
- Probability: low – injury or mortality to Pacific salmon is unlikely given the effectiveness of the proposed mitigation and the expectation that individuals in close proximity of the piles will relocate during preparatory activities such as pile placement and installation of the bubble curtain.
- Confidence: high – based on a reasonable understanding by the assessment team of the cause-effect relationships between underwater noise levels produced during pile-driving and injury or mortality to Pacific salmon, and the effectiveness of the proposed mitigation.

7.6.9.7 Summary

As identified in Table 7.6.9-3, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on marine fish or fish habitat indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operations activities at the Westridge Marine Terminal on marine fish and fish habitat will be not significant.

7.6.10 Wildlife and Wildlife Habitat

The Westridge Marine Terminal is an existing industrial site and all onshore work will be conducted within the existing fenced area. There are residual patches of vegetation that will be affected by Project activities. However, given that the site is highly disturbed and all work will occur within the existing fenced area, wildlife and wildlife habitat value at the Westridge Marine Terminal is considered to be low. Wildlife indicators that may be affected by Project activities at the Westridge Marine Terminal include coastal riparian small mammals, bats, mature/old forest birds, early seral forest birds, riparian and wetland birds, rusty blackbird, western screech-owl, great blue heron, bald eagle, common nighthawk, northern goshawk, olive-sided flycatcher, and pond-dwelling amphibians.

The assessment of effects on wildlife and wildlife habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, other ancillary facilities, and the Westridge Marine Terminal), since the components will have similar effect pathways (*i.e.,* change in habitat movement and mortality risk) on wildlife indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for wildlife indicators.

The assessment of effects on wildlife and wildlife habitat for the Project as a whole is presented in Section 7.2.10. Table 7.2.10-6 and accompanying discussion in Section 7.2.10.9 provide the evaluation of potential residual effects of the construction and operations of the Westridge Marine Terminal on mammal indicators, Table 7.2.10-9 and accompanying discussion in Section 7.2.10.10 provide the evaluation of potential residual effects of the construction and operations of the Westridge Marine Terminal on bird indicators, and Table 7.2.10-12 and accompanying discussion in Section 7.2.10.11 provide the evaluation of potential residual effects of the construction and operations of the Westridge Marine Terminal on amphibian indicators.

7.6.11 Marine Mammals

Marine mammals have high ecological value and play key roles in marine food webs, both as top predators and as prey. They also have high cultural and socio-economic importance to Aboriginal communities, British Columbians, Canadians, and visitors from abroad and are often the focal point of whale-watching and tourism activities on the coast of BC.

7.6.11.1 Assessment Indicators and Measurement Endpoints

The assessment indicators for marine mammals were selected from a list of all marine mammal species known to occur in Burrard Inlet with preference for species likely to occur with regularity in the Marine Mammal LSA. The only species that met this criterion was the Pacific harbour seal (‘harbour seal’; *Phoca vitulina richardsi*). Therefore, the harbour seal was selected as the assessment indicator for marine mammals. While the assessment focuses on effects to harbour seals, mitigation will also be applied to reduce potential adverse environmental effects on less common marine mammal species.

Feedback on marine mammal indicator selection was solicited from Environment Canada at a meeting held on April 16, 2013. Environment Canada did not raise any concerns with the selection of the harbour seal, but did suggest that the river otter be considered for possible inclusion. Although river otters in Burrard Inlet forage in intertidal and shallow subtidal habitats, they dwell in burrows on land and are generally classified as a terrestrial mammal. For this reason, the harbour seal was considered a more appropriate indicator for assessing potential Project effects on marine mammals. Mitigation measures developed to reduce effects of marine construction activities on marine mammals are assumed to also reduce potential effects to river otters.

No issues were raised concerning selection of the harbour seal indicator at any of the open houses or ESA Workshops.

No pathways of effects to marine mammals associated with Project operations were identified. For an assessment of the effects of marine transportation on marine mammals, see Section 4.3.7 of Volume 8A.

Table 7.6.11-1 lists the indicator used to assess potential effects on marine mammals, the measurement endpoints used and the rationale for their selection.

TABLE 7.6.11-1

ASSESSMENT INDICATOR AND MEASUREMENT ENDPOINTS FOR MARINE MAMMALS

Marine Mammal Indicator	Measurement Endpoints	Rationale for Indicator Selection
Pacific harbour seal (*Phoca vitulina richardsi*)	• Potential for (1) injury, and (2) sensory disturbance due to in-water Project construction activities (evaluated qualitatively) • Relative importance and quality of marine mammal habitat affected	• Could be affected by the Westridge Marine Terminal construction. • Most common and abundant marine mammal in the Marine Mammal LSA and Marine RSA.

7.6.11.2 Spatial Boundaries

Spatial boundaries for the assessment of potential Project effects on marine mammals are defined as follows.

- Project Footprint: the area directly affected by construction of the Westridge Marine Terminal.
- Marine Mammal LSA: the ZOI likely to be affected by construction and operations of the Westridge Marine Terminal, defined as the area within 500 m of the proposed water lease expansion.
- Marine RSA: the area where the direct and indirect influence of other activities could overlap with Project-specific effects and cause cumulative effects on marine mammals. This includes the area of Burrard Inlet east of the First Narrows, including Indian Arm and Port Moody Arm.

The ZOI for the Marine Mammals LSA corresponds to the exclusion zone that will be monitored for cetaceans and marine mammal species at risk during pile installation activities. The 500 m radius has been applied for numerous other marine terminal development projects in BC.

Study area boundaries for marine mammals are shown on Figures 6.2-1 and 6.2-2.

7.6.11.3 Marine Mammal Context

Marine Mammal Presence

Marine mammal diversity and abundance in Burrard Inlet is generally considered low. Up until the late nineteenth century, whales, including the humpback whale, were a common sight in Burrard Inlet (BIEAP 1995). Even fin whales, generally more common to offshore and exposed coastal waters, were historically seen on occasion in the more protected waters of the nearby Strait of Georgia (Pike and MacAskie 1969 *in* Gregr *et al.* 2006). At least 95 humpback whales were commercially hunted and killed in the Strait of Georgia and Queen Charlotte Strait between 1866 and 1873 (Nichol *et al.* 2002). A whaling station was even established at Page's Lagoon near Nanaimo from 1907 to 1909 to hunt humpback whales that overwintered in the Strait of Georgia (Merilees 1985 *in* Nichol *et al.* 2002). Whaling-related BC coastal geographical names in the Strait of Georgia, such as Whaling Station Bay (Hornby Island), Blubber Bay (Texada Island), and Whaletown (Cortes Island) attest to previous whale presence in this region (Merilees 1985 *in* Nichol *et al.* 2002).

The most abundant and common marine mammal species currently observed in Burrard Inlet is the Pacific harbour seal, which is a year-round resident within the Inlet and throughout the coastal waters of BC (DFO 2010, Hanrahan 1994 *in* Haggarty 2001). Historically, harbour seals (in addition to salmon and eulachon) were a major source of food for Aboriginal communities of Burrard Inlet (BIEAP 1995). Currently the seals are a viewing attraction for tourists and local residents, and can be found basking in the sun on rocks or piers along the seawall, or surfacing in the water beside boats and kayaks.

There are occasional, though relatively rare, sightings of other marine mammal species in Burrard Inlet, including Steller (*Eumetopias jubatus monteriensis*) and California (*Zalophus californianus*) sea lions, northern fur seal (*Callorhinus ursinus*) and harbour porpoise (*Phocoena phocoena*) (Marine Mammal Research Unit 2012). Killer whale (*Orcinus orca*), Pacific white-sided dolphin (*Lagenorhynchus* *obliquidens*), false killer whale (*Pseudorca crassidens*), grey whale (*Eschrichtius robustus*), humpback whale (*Megaptera novaeangliae*) and minke whale (*Balaenoptera acutorostrata*) have also made the occasional appearance in Burrard Inlet or nearby waters (BC Cetacean Sightings Network 2013), though their use of this habitat is limited and sightings are relatively uncommon. At this time, there is no officially designated critical habitat or DFO Important Areas (Jamieson and Levesque 2012a,b) for marine mammal species at risk in the Marine RSA.

Injury Criteria and Disturbance Thresholds

Noise-induced auditory injury (*i.e.,* permanent or temporary threshold shifts [PTS and TTS, respectively]), avoidance and sensory disturbance may compromise marine mammal feeding efficiency, predator detection, and/or migratory success, and can lead to reduced health and possibly death (Richardson *et al.* 1995). DFO does not have any formal guidance or thresholds for assessing the potential effects of underwater noise on marine mammals (with the exception of seismic surveys, for which it has a statement of Canadian practice; DFO 2013f). In the absence of Canadian legislation or guidelines, the assessment considered two alternative sets of commonly-applied thresholds, described in the following text.

The first set of criteria, developed by Southall *et al.* (2007), is used primarily to evaluate the potential for injury (*i.e.,* PTS or TTS). Sound levels capable of inducing PTS and TTS in marine mammals are not well established; PTS has not been observed in any marine mammal, and TTS has only been observed in a few species of pinnipeds and small toothed whales (Southall *et al.* 2007). Estimates of sound levels capable of inducing auditory injury are therefore developed by extrapolating from known or predicted marine mammal auditory thresholds (Richardson *et al.* 1995, Southall *et al.* 2007). The injury criteria proposed by Southall *et al.* in 2007 are the most recent generalized estimates of TTS- and PTS-inducing sound pressure levels (SPLs) and sound exposure levels (SELs), and are based on a comprehensive analysis of existing research. Southall *et al.*'s (2007) proposed injury criteria for SELs and peak SPLs of single pulse, multiple pulse and non-pulse sound sources are summarized in Table 7.6.11-2 for cetaceans (*i.e.,* whales, dolphins, and porpoises) and pinnipeds (*i.e.,* seals and sea lions).

The second set of thresholds is that currently used by the National Oceanic and Atmospheric Administration (NOAA) to issue *Marine Mammal Protection Act* permits and conduct *Endangered Species Act* Section 7 consultations. These are considered interim conservative thresholds to be used until formal guidance is available. The NOAA criteria are frequently used to evaluate behavioural disruption because Southall *et al*. (2007) did not recommend specific numeric criteria (distinct from TTS-onset) for the onset of behavioural disturbance from multiple or non-pulse sound sources. The NOAA criteria also set thresholds for SPLs for impulsive noises deemed capable of potentially causing PTS or TTS. The Southall *et al.* (2007) metrics (*i.e.,* peak SPL and SEL) are generally considered more appropriate metrics for assessing potential effects of impulsive sounds such as pile driving; however, since the NOAA criteria may be more conservative, both metrics are used in the assessment of potential injury. The NOAA criteria are summarized alongside Southall *et al.*'s (2007) in Table 7.6.11-2. Different thresholds are proposed for impulsive (*e.g.,* pile driving) noise versus non-pulse (*e.g.,* vibratory pile driving, pile drilling, and dredging) sound sources, and for pinnipeds versus cetaceans. While NOAA is currently revising its criteria, with specific reference to different sound sources (*e.g.,* explosives; Finneran and Jenkins 2012), criteria specific to pile driving and/or dredging are not yet available.

The term "auditory injury" as used by NOAA or Southall *et al.* is intended to refer strictly to permanent auditory damage (*i.e.,* PTS; as per the three columns of injury criteria presented in Table 7.6.11-2). However, the terms 'permanent auditory injury' and 'temporary auditory injury' are used in this assessment interchangeably with the terms PTS and TTS, respectively (*i.e.,* this assessment considers TTS to be a form of injury, even if only temporary in nature).

Southall *et al.* (2007) developed their proposed PTS criteria based on sound levels predicted to cause TTS. The SEL thresholds used by Southall *et al.* for TTS onset were 183 dB re: 1 μPa^2-s for cetaceans and 171 dB re: 1 μPa^2-s for pinnipeds (PTS onset was predicted by adding an additional 15 dB exposure to pulsed sounds). For peak broadband SPLs, TTS onset was set at 224 dB re: 1 μPa for cetaceans and 212 dB re: 1 μPa for pinnipeds (values used to assess PTS were determined by adding 6 dB; Southall *et al.* 2007). Threshold values capable of causing temporary auditory damage are not addressed by the NOAA proposed criteria, nor are PTS or TTS thresholds from non-pulse sound sources (NOAA Fisheries 2013a).

TABLE 7.6.11-2

MARINE MAMMAL INJURY CRITERIA AND SENSORY DISTURBANCE THRESHOLDS USED IN THE ASSESSMENT OF UNDERWATER NOISE

Species Group	Southall *et al.* and NOAA Injury Criteria (PTS)			Southall *et al.* 'Behavioural Disturbance' Criteria (same for TTS)		NOAA 'Behavioural Disruption' Thresholds
	Peak SPL[a] (dB_{peak} re: 1μPa)	SEL[a] (dB re: 1 μPa^2-s)	RMS SPL[b] (dB_{RMS} re: 1 μPa)	Peak SPL[a] (dB_{peak} re: 1μPa)	SEL[a] (dB re: 1 μPa^2-s)	RMS SPL[b] (dB_{RMS} re: 1 μPa)
Pinnipeds	218 (single, multiple, and non-pulse)	186 (pulse); 203 (non-pulse)	190 (pulse)	212 (single pulse)	171 (single pulse)	160 (pulse); 120 (non-pulse)
Cetaceans	230 (single, multiple, and non-pulse)	198 (pulse); 215 (non-pulse)	180 (pulse)	224 (single pulse)	183 (single pulse)	160 (pulse); 120 (non-pulse)

Sources: a. Values taken from Southall *et al.* 2007. b Values taken from NOAA Fisheries 2013a.

Notes:
- SPL = Sound Pressure Level; SEL = Sound Exposure Level; RMS = Root Mean Square; PTS = Permanent Threshold Shift
- Impact pile driving is an example of a multiple pulse noise, while vibratory pile driving is an example of a non-pulse noise.
- Decibels re: 1 μPa are the accepted unit for measuring underwater sound as it relates to marine mammals (Richardson *et al.* 1995, Southall *et al.* 2007); however, there are different metrics (*i.e.,* peak vs RMS) for measuring and reporting decibels. SELs are a measure of received sound energy and values presented in Table 7.6.11-2 were developed to reflect M-weighted SELs by functional hearing group (see Southall *et al.* 2007); however, only unweighted values are discussed in this assessment. Comparison of unweighted source levels and M-weighted thresholds is expected to be conservative.
- The three columns of injury criteria above reflect only the onset levels for permanent auditory damage, or PTS (not TTS). The Southall *et al.* proposed behavioural disturbance criteria are the same as the estimated TTS onset values.

7.6.11.4 Potential Effects and Mitigation Measures

Identified Potential Effects

The potential effects associated with construction at the Westridge Marine Terminal are listed in Table 7.6.11-3. Identification of effects was based on the results of a literature review, desktop analysis, engagement with regulatory authorities and other stakeholders (Section 3.0), and the professional experience of the assessment team. There are no identified pathways of effects for marine mammals associated with operational activities of the Westridge Marine Terminal. For the assessment of effects associated with increases in Project-related marine traffic, see Volume 8A.

Construction of the marine loading berths will involve the installation of large diameter steel piles (*i.e.,* pile driving) and may involve a small amount of dredging. Pile driving can result in the generation of high energy pressure waves that radiate outward from the sound source. While mobile marine organisms such as marine mammals are generally expected to avoid very loud in-water construction activities, noise from these activities could still result in temporary or permanent auditory damage (*i.e.,* TTS or PTS) to individuals in close proximity to pile driving (Richardson *et al.* 1995). Predicted underwater noise source levels associated with pile driving were presented in Table 7.6.9-5. Source levels for pile driving and dredging are discussed in Section 7.6.9.6 Marine Fish and Fish Habitat. Noise levels associated with dredging are typically lower than pile driving (Richardson *et al*. 1995) and are not expected to cause either PTS or TTS.

The production of loud underwater construction noise (*i.e.,* from pile driving, pile drilling, or dredging) could also cause sensory disturbance to marine mammals. This may result in behavioural responses such as habitat avoidance, changes in activity state (*e.g.,* feeding, resting, or travelling) and/or interference with communication and perception of sounds (*i.e.,* masking; Richardson *et al.* 1995). The extent of sensory disturbance depends on a number of factors, including: the source level, frequency, and duration of the underwater noise, the context and the species in question.

To determine potential effects of construction-related underwater noise on marine mammals, source sound levels (based on literature values) were contrasted with the Southall *et al.* (2007) and NOAA threshold sound levels predicted to cause auditory harm or induce behavioural responses.

The summary of mitigation measures provided in Table 7.6.11-3 was principally developed in accordance with industry best management practices, NOAA Fisheries' Guidance for Developing a Marine Mammal

Monitoring Plan (NOAA Fisheries 2013b), and the professional experience of the assessment team. Further details on potential residual effects and the key mitigation measures are provided in the following subsections.

TABLE 7.6.11-3

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AT THE WESTRIDGE MARINE TERMINAL ON MARINE MAMMALS

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Marine Mammal Indicator – Harbour Seal			
1.1 Permanent or temporary auditory injury	LSA	• Use a vibratory method of pile installation instead of an impact hammer, if feasible [Section 8.2]. • Deploy bubble curtains during pile installation to reduce underwater noise levels where an impact hammer is required for pile installation [Section 8.2]. • Conduct an acoustic survey in order to establish the effectiveness of the bubble curtain, prior to the commencement of the pile installation activity [Section 8.2]. • Complete a marine mammal survey prior to any marine activities (*i.e.,* dredging of the marine environment from onshore and/or in the marine environment, drilling, pile installation, infilling), by trained personnel to determine the presence of marine mammals within the area. If any cetaceans or species at risk are observed in or within close proximity to the predetermined exclusion zone, all marine operations will be temporarily suspended (or rescheduled if deemed necessary) until the marine mammal(s) has left the exclusion zone and does not reappear within 30 minutes [Section 8.2]. • Sound levels will be monitored by qualified personnel both onshore and in-water, during loud underwater construction activities (*e.g.,* pile installation activities) in order to allow for adjustments to the radius of the exclusion zone based on changes in field conditions. The number of personnel required for monitoring will depend on the size and extent of the pre-determined exclusion zone. Monitoring will take place for 30 minutes prior to and during marine construction activities. In the event that cetaceans or species at risk are observed within or near the exclusion zone, temporarily suspend or reschedule all construction activity if deemed necessary. Resume activities once the observed marine mammal(s) has left the exclusion zone and does not reappear within 30 minutes [Section 8.2].	• No residual effect identified related to permanent auditory injury (see Section 7.6.11.5). • Temporary auditory injury of harbour seals or other marine mammals due to underwater noise produced during pile driving.
1.2 Sensory disturbance	RSA	• Use a vibratory method of pile installation instead of an impact hammer, if feasible [Section 8.2]. • Deploy bubble curtains during pile installation to reduce underwater noise levels where an impact hammer is required for pile installation [Section 8.2]. • Conduct an acoustic survey in order to establish the effectiveness of the bubble curtain, prior to the commencement of the pile installation activity [Section 8.2].	• Sensory disturbance of harbour seals or other marine mammals due to underwater noise produced during pile driving or dredging.

Notes: 1 LSA = Marine Mammal LSA; RSA = Marine RSA.
2 Detailed mitigation measures are outlined in the Westridge Marine Terminal EPP (Volume 6D).

Mitigation Measures

As noted above, and as illustrated in Table 7.6.9-5, noise levels produced during pile driving are highly variable and situation-specific. However, use of a vibratory driver generally produces SPLs that are roughly 25 dB lower (SELs of 10-15 dB lower), on average, than those produced by an impact hammer in a comparable setting and vibratory drivers do not produce the high impulse signatures of impact pile driving (Illingworth and Rodkin Inc. 2007, McCauley and Salgado Kent 2008). The preferred installation method is therefore vibratory driver, for its decreased noise production.

Where a vibratory driver cannot be used due to engineering constraints (*e.g.,* unfavourable substrate conditions), an impact hammer will likely be used. If an impact or hydraulic hammer is required for pile installation, Trans Mountain will implement several mitigation measures when driving the piles. These recommendations are in accordance with *Best Management Practices for Pile Driving and Related Operations* (BMPs) for driving steel pipe piles with a diameter greater than 61 cm (24 inches). The BMPs were developed by the BC Marine and Pile Driving Contractors Association (2003) to minimize impact to fish habitat. Bubble curtains will be deployed over the full length of the wetted pile to assist in attenuating sound levels. A hydrophone will be used to monitor pressure levels during pile-driving, so as to reduce potential fish injury or mortality (see Section 7.6.9). This hydrophone will also be monitored at the onset of pile-driving to confirm the assumptions concerning source levels, potential exceedance of marine mammal auditory injury levels, and effectiveness of mitigation measures.

Bubble curtains are a potential mitigation method for impact pile driving. While there are a variety of styles, they all rely on the same basic principle: surrounding the pile with air assists in attenuating the noise produced during impact. When designed and used effectively, bubble curtains have generally been shown to provide a reduction in SPLs and SELs of between 10 and 15 dB (Illingworth and Rodkin Inc. 2007). Actual attenuation values will vary depending on factors such as design of the bubble curtain, installation, current velocity, water depth, and substrate type (Koschinski 2011). Lucke *et al.* (2011) showed that installation of a bubble curtain during pile driving of wooden piles reduced mean SEL values (over a continuous sequence of 95 strikes) by 13 dB (standard deviation 2.5 dB), and resulted in the termination of avoidance reactions by harbour porpoises. Should use of a vibratory driver not be technically feasible, details concerning appropriate type and usage of bubble curtains will be discussed with DFO.

A marine mammal monitoring program will be implemented to enforce a pre-determined exclusion zone during pile driving operations. The area of the exclusion zone (generally set at 500 m from the sound source) will be confirmed through discussion with DFO, and may involve acoustic modelling if deemed necessary. Trained observers will monitor the Marine Mammal LSA and surrounding waters for all marine mammals during loud underwater construction activities. Pile driving will only occur during daylight hours to ensure that marine mammals can be seen if they approach or enter the exclusion zone. If cetaceans or species at risk are detected within the exclusion zone, the underwater construction activity will be immediately stopped until the marine mammal has been observed to exit the exclusion zone, or has not been re-sighted for 30 minutes. This additional mitigation measure is expected to reduce potential residual effects for all species of marine mammals in the Marine Mammal LSA with the exception of harbour seals. While the marine mammal monitoring program has been designed as an additional safeguard to protect cetaceans and species of conservation concern, current Canadian practice (*e.g.,* the Statement of Canadian Practice with respect to the Mitigation of Seismic Sound in the Marine Environment; DFO 2013f) does not generally mitigate for effects of loud underwater noise for non-listed pinnipeds.

7.6.11.5 Potential Residual Effects

The potential residual environmental effects on harbour seals associated with construction activities at the Westridge Marine Terminal (Table 7.6.10-3) are:

- temporary auditory injury of harbour seals or other marine mammals due to underwater noise produced during pile driving; and
- sensory disturbance of harbour seals or other marine mammals due to underwater noise produced during pile driving or dredging.

Potential effects on the marine mammal indicator related to permanent auditory injury as a result of construction activities at the Westridge Marine Terminal was assessed but determined to not constitute a likely residual effect and, consequently, no residual effect is anticipated (Table 7.6.10-3). The rationale for this conclusion is presented below.

<u>Permanent Auditory Injury</u>

Should the Project be approved, pile driving and dredging are assumed to take place intermittently over the course of approximately 2 years. Based on typical maximum broadband source levels for a clamshell dredge (*i.e.,* 167 dB_{peak} re: 1 μPa at 1 m) presented in Richardson *et al.* (1995), underwater noise produced during dredging is not expected to reach levels capable of causing TTS or PTS. As such, the assessment of auditory injury focuses on noise produced during pile driving activities.

Based on sound levels measured during other construction projects (*i.e.,* Illingworth and Rodkin Inc. 2007), and assuming the Project uses steel piles up to 1.5 m in diameter installed using an impact hammer, peak SPLs and SELs predicted for construction of the Westridge Marine Terminal are expected to approach, but not exceed Southall *et al.*'s auditory injury criteria, even in the absence of mitigation (see Tables 7.6.9-5 and 7.6.11-2 above). Based on these criteria, no permanent auditory injury to marine mammals is expected. However, using NOAA's more conservative RMS SPL thresholds of 190 and 180 dB re: 1 μPa (for pinnipeds and cetaceans, respectively), unmitigated noise from pile driving would be expected to exceed those thresholds by 5 and 15 dB, respectively. The likelihood of permanent physical injury for marine mammals associated with the construction of the Westridge Marine Terminal will be greatly reduced or predicted to be eliminated through the implementation of mitigation measures (Table 7.6.11-3).

Trans Mountain has committed to implementing several mitigation measures when driving the piles. If technically feasible, a vibratory driver would be used in lieu of an impact hammer. Based on the conservative use of surrogate literature values for a typical 1.8 m steel pile installed using a vibratory driver (Table 7.6.9-5; 1.4 m steel pile source level not available), this form of mitigation would lower RMS sound pressure levels at 10 m from the source to 170 dB re: 1 μPa. Although NOAA does not have injury thresholds for continuous sound sources such as vibratory driving, the SEL and peak SPL values for use of this vibratory driver far well below Southall *et al.* injury criteria (*i.e.,* SELs from the literature are 33 dB below auditory injury level for pinnipeds, and 45 dB below for cetaceans, while peak SPLs are 35 dB and 47 dB below, respectively). Use of a vibratory driver is therefore the preferred option, and if used, residual effects of permanent auditory damage would not be expected for marine mammals in the LSA.

In the case where use of an impact hammer is deemed necessary for engineering reasons, Trans Mountain will implement use of bubble curtains. Assuming a conservative value of 10 dB of attenuation, the use of an appropriately-designed bubble curtain during the assumed Project pile driving installation scenario would reduce SELs to 175 dB re: 1 μPa^2-s and $SPLs_{RMS}$ to 185 dB re: 1 μPa (at 10 m from the pile). While these values fall below Southall *et al.*'s criteria, and below NOAA's criteria for pinnipeds, they remain above NOAA's criteria for cetaceans. Noise associated with pile driving activities is therefore not expected to cause permanent auditory damage to pinnipeds (including the harbour seal indicator) in the Marine Mammal LSA, regardless of the mitigation measure ultimately applied.

The Marine Mammal LSA is not considered to be high quality habitat for marine mammals and the predominant species is the common harbour seal. However, cetaceans (including species at risk) may be exposed to sound levels capable of causing permanent auditory damage if they are present in the Marine Mammal LSA during construction. As such, the marine mammal monitoring program (as detailed above) will be implemented as an additional mitigation measure to ensure that should cetaceans or marine mammal species of conservation concern make the occasional appearance in the Marine Mammal LSA, these individuals will not be permanently injured by loud underwater noise.

The above suite of mitigation measures is predicted to eliminate the risk of PTS to marine mammals. The potential for permanent auditory injury is therefore not carried forward into the assessment of potential residual effects, as no residual effects are predicted.

7.6.11.6 Significance Evaluation of Potential Residual Effects

A combination of quantitative and qualitative assessments of marine mammals was determined to be the most appropriate approach to evaluate the significance of potential residual environmental effects. While there are thresholds for auditory injury and sensory disturbance, and the source levels of in-water construction activities can be estimated with reasonable confidence (in a conservative fashion), the responses of marine mammals to underwater noise vary considerably among species and even among individuals of the same species. Consequently, the evaluation of significance of the potential residual effects relies on both the application of standards and guidelines and the professional judgment of the assessment team.

Table 7.6.11-4 provides a summary of the significance evaluation of the potential residual environmental effects of construction activities at the Westridge Marine Terminal on marine mammals. As previously noted, no residual effects associated with operations activities of the Westridge Marine Terminal are expected. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.6.11-4

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AT THE WESTRIDGE MARINE TERMINAL ON MARINE MAMMALS

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Marine Mammal Indicator – Harbour Seal									
1(a)	Temporary auditory injury of harbour seals or other marine mammals due to underwater noise produced during pile driving.	Negative	LSA	Short-term	Isolated	Medium-term	Medium	Low	High	Not significant
1(b)	Sensory disturbance of harbour seals or other marine mammals due to underwater noise produced during pile driving or dredging.	Negative	RSA	Short-term	Isolated	Medium-term	Medium	High	High	Not significant

Notes: 1 LSA = Marine Mammal LSA; RSA = Marine RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Marine Mammal Indicator – Harbour Seal

The following subsections provide the evaluation of significance of potential residual effects on the harbour seal indicator and other marine mammals.

Temporary Auditory Injury of Harbour Seals or Other Marine Mammals Due to Underwater Noise Produced During Pile Driving

A comprehensive mitigation program has been developed to reduce or eliminate potential harm to marine mammals during construction of the Westridge Marine Terminal. Use of mitigation measures (*i.e.,* vibratory driver or bubble curtains) is generally expected to reduce underwater noise levels to below levels likely to cause TTS. However, sound levels capable of causing the onset of TTS are still not well understood, empirical evidence is limited, and results can vary dramatically between species or even individuals (*e.g.,* Kastelein *et al.* 2012a). For example, harbour porpoises are thought to be one of the most sensitive species to construction noise, and TTS has been found to occur in harbour porpoises at sound exposure levels approximately 20 dB below the threshold for which they occurred in harbour seals (Kastelein *et al.* 2011). In a study of TTS in harbour porpoise by Kastelein *et al.* (2012b), the lowest SEL (151 dB re: 1 μPa^2-s) found to cause statistically significant TTS occurred following exposure to an SPL_{RMS} of 124 dB re: 1 μPa for 7.5 minutes. In this same study, recovery time following TTS varied between 4 and 96 minutes, depending on the exposure level, duration, and the degree of TTS induced (Kastelein *et al.* 2012b).

While mitigation measures are expected to be effective at reducing the occurrence of TTS, a small number of marine mammals in the vicinity of pile driving may still experience TTS. Harbour seals are the most likely species to be affected, as they are the most common species in the area, and they will not have the additional protection associated with the marine mammal monitoring program. These individuals are expected to vacate the area should underwater noise exceed TTS levels, thereby reducing their length of exposure. Effects will be, by definition, temporary in nature, and are expected to dissipate within a manner of minutes to hours following exposure. The likelihood of noise levels capable of causing TTS will decrease with distance from the source. The potential for TTS is therefore considered more likely within the Project Footprint itself and is not expected to extend beyond the Marine Mammal LSA. To be exposed to sound levels capable of causing TTS, marine mammals therefore need to be in close proximity to the piles at the time of pile-installation. The Marine Mammal LSA is not considered high quality marine mammal habitat, and while harbour seals are expected to be regularly observed in the area, they are also expected to move away from areas where SPLs exceed TTS or PTS levels. Sightings of other species of marine mammal are expected to be uncommon, but even rare occurrences will be mitigated by the additional measures in place for cetaceans and species at risk. Based on the above assessment, the effects of temporary auditory injury of harbour seals or other marine mammals due to underwater noise produced during pile driving are determined to be not significant.

At the time of this assessment, exact engineering details concerning the nature of the pile driving activities were not available, although relevant examples from other projects are known from the literature. There is also some uncertainty regarding the type of mitigation measures that will be used (*e.g.,* if vibratory pile installation is feasible) and the sound levels that will ultimately be produced. However, determination of confidence has been based on the engineering assumptions made, and the presumed use of appropriate mitigation measures. Additionally, while a variety of thresholds and criteria exist for assessing PTS, further research is warranted in developing a clear understanding of SPLs or SELs capable of causing auditory injury (permanent or temporary) in marine mammals. Whether SPLs produced actually result in auditory damage will also depend in large part on the species and individuals exposed, the exact nature of the sound, and the context and duration of exposure. A limited number and diversity of marine mammals are expected to use the Marine Mammal LSA on a regular basis, and despite the above uncertainties, the comprehensive mitigation program detailed above (including additional measures for species at risk) is expected to reduce or eliminate potential harm to marine mammals. As such, confidence in the significance conclusion is rated as high (Table 7.6.11-4, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Mammal LSA – should underwater SPLs exceed thresholds for causing TTS even after mitigation, these levels are likely to dissipate within a relatively short distance from the source. Potential residual effects associated with temporary auditory injury are, therefore, expected to be confined to the LSA.
- Duration: short-term – underwater SPLs potentially capable of causing TTS will only be associated with pile-driving activities (*i.e.,* approximately 2 years). While potential effects may extend for a brief duration into the operations phase, the actual event associated with the effect (*i.e.,* production of loud underwater noise during pile driving) will be restricted to the construction phase.
- Frequency: isolated – underwater SPLs potentially capable of causing TTS will only be associated with intermittent pile-driving activities during construction (*i.e.,* on and off for approximately 2 years). While potential effects may extend into the operations phase, the actual event associated with the effect (*i.e.,* production of loud underwater noise during pile driving) will be restricted to the construction phase.
- Reversibility: medium-term – the potential for repeated exposure over the length of the construction phase means that the overall effect is likely to be reversible in the medium-term (*i.e.,* greater than 2 years).
- Magnitude: medium – mitigated sound levels are not expected to exceed PTS thresholds, and while they may exceed TTS thresholds for pinnipeds, cetaceans and species at risk will receive additional protection through monitoring.
- Probability: low – a comprehensive mitigation program is expected to reduce or eliminate potential auditory injury to marine mammals.
- Confidence: high – determination of confidence is based on the engineering assumptions made, the limited number and diversity of marine mammals in the Marine Mammal LSA, and the presumed use of appropriate mitigation measures.

Sensory Disturbance of Harbour Seals or Other Marine Mammals Due to Underwater Noise Produced During Pile Driving or Dredging

Sound levels produced during typical mitigated pile driving and dredging activities that are below PTS or TTS levels of concern may continue to elicit behavioural responses that affect the health of marine mammals (Richardson *et al.* 1995, Nowacek *et al.* 2007, Southall *et al.* 2007). The extent of sensory disturbance depends on numerous factors, including the source level, frequency, and attenuation rate of the underwater sound, as well as the species, proximity, activity state, and individual marine mammal in question (Richardson *et al.* 1995, Southall *et al.* 2007). The form of sensory disturbance may also vary widely and can range from non-observable physiological responses, such as increases in stress hormones and heart rate or decreases in ability to detect other sounds in the environment (*i.e.,* masking) to overt physical reactions such as startle responses. Habitat avoidance is among the most severe forms of behavioural responses, as displaced animals may be excluded from important foraging or breeding areas (Richardson *et al.* 1995, Southall *et al.* 2007).

Southall *et al*.'s initial proposed behavioural disturbance criteria are also the estimated TTS onset values and apply only to single pulses (*i.e.,* would not apply to the multiple pulses that occur during pile driving). As such, only the NOAA behavioural disruption criteria are considered here (see Table 7.6.11-2). This assessment further assumes that sound levels capable of causing injury (as discussed above) will also result in sensory disturbance; therefore, the following discussion focuses only on responses to underwater noise at levels below those capable of causing injury.

Noise levels within the Marine Mammal LSA and potentially in portions of the Marine RSA are expected to exceed the NOAA threshold for behavioural disruption (*i.e.,* 160 dB_{RMS} re: 1 μPa for both cetaceans and pinnipeds). However, based on a review of limited data concerning exposure of pinnipeds to multiple underwater pulses, Southall *et al.* (2007) generally found that exposures in the ~150 to 180 dB_{RMS} re: 1 μPa range had limited potential to induce avoidance behavior in pinnipeds. Ringed seals (close relatives to harbour seals) in Prudhoe Bay, Alaska exhibited little or no reaction to mean underwater SPLs from terrestrial impact pipe-driving pulses of 151 dB_{RMS} re: 1 μPa (Blackwell *et al.* 2004). SPLs near the bottom of the water column may have approached 160 dB_{RMS} re: 1 μPa, yet there was no observed change in diving behaviour and one seal actually approached to within 3 m of shore (46 m from the pipe installation activities). The authors hypothesized that the seals in this region were habituated to industrial sounds (Blackwell *et al.* 2004). While harbour seals in the Marine Mammal LSA and portions of the Marine RSA will be able to detect pile driving activity, it remains possible that they habituate to these sounds over the course of the construction phase.

Most studies report that marine mammal behaviour returns to normal after sound production ceases (Richardson *et al.* 1995, Southall *et al.* 2007); however, the length of time can vary. A study by Brandt *et al.* (2011) showed that harbour porpoise acoustic activity was reduced by 100% during the first hour after pile driving activities, at a distance of 2.6 km from the construction site (*i.e.,* the porpoise were likely displaced from within this area). Acoustic activity within 2.6 km remained below normal levels for 24 to 72 hours. The length of time to recover gradually decreased with increasing distance; however, a negative effect was detectable out to a mean distance of 17.8 km (Brandt *et al.* 2011). These results are comparable to those of Tougaard *et al.* (2009) who detected harbour porpoise responsiveness to pile driving at a distance of 20 km. Both of these studies involved harbour porpoises (which are expected to be more sensitive to construction sounds than harbour seals) and installation of steel monopile foundations (*i.e.,* 4 m diameter) for offshore wind turbines. Mitigation measures such as bubble curtains have proved successful at reducing effects of smaller operations, as captive harbour porpoises that showed avoidance reactions during unmitigated piling were observed to return to normal behaviour when a bubble curtain was activated. Piling activity in this case involved 40 cm wood piles installed at a distance of between 100 and 175 m from a porpoise enclosure (Lucke *et al.* 2011).

It is difficult to predict with certainty how different species, or even individuals, will respond to underwater noise associated with construction of the Westridge Marine Terminal. While certain species (*e.g.,* harbour porpoise) appear more likely to display adverse reactions than others (*e.g.,* harbour seals), the Marine RSA is not considered prime marine mammal habitat, and it is likely that the primary species to experience exposure is the harbour seal. Pile driving will be intermittent but will not occur continuously over the two-year construction phase, and it is expected that the time between pile driving activities will allow harbour seals to recover, or potentially even habituate to the activity. While startle responses and small-scale avoidance reactions remain possible, these are expected to be temporary and of short duration (*i.e.,* immediately upon onset of pile driving) and recovery is expected to be rapid. Likewise, while there may be temporary interruption of foraging or resting, normal activities are expected to resume once the immediate perceived threat has passed. Underwater noise from construction may result in an unknown degree of communication masking, and may reduce harbour seals' ability to detect predators or detect and communicate with conspecifics. As with other aspects of sensory disturbance, this effect will decrease with increasing distance from the Marine Mammal LSA.

The comprehensive mitigation program discussed above will also be effective at reducing the degree of sensory disturbance to marine mammals during construction of the Westridge Marine Terminal. While noise levels are likely to exceed NOAA's threshold for behavioural disruption within the Marine Mammal LSA and potentially small portions of the Marine RSA, the literature suggests that pinnipeds may habituate to these sounds. The Marine Mammal LSA is not considered high quality marine mammal habitat, and sightings of other species of marine mammal are expected to be uncommon. Rare occurrences of more sensitive species such as harbour porpoises may result in temporary avoidance responses to construction activities. Based on the above assessment, the effects of sensory disturbance of harbour seals or other marine mammals due to underwater noise produced during pile driving are determined to be not significant.

At the time of this assessment, exact engineering details concerning the nature of the pile driving activities were not available, although relevant examples from other projects are known from the literature. There is also some uncertainty regarding the type of mitigation measures that will be used (*e.g.,* if vibratory pile installation is feasible) and the sound levels that will ultimately be produced. However, determination of confidence has been based on the engineering assumptions made, and the presumed use of appropriate mitigation measures. Behavioural responses to underwater noise vary widely within and between species, and to what degree SPLs produced will actually result in sensory disturbance will depend in large part on the species and individuals exposed, the exact nature of the sound, and the context and duration of exposure. A limited number and diversity of marine mammals are expected to use the Marine Mammal LSA on a regular basis, and despite the above uncertainties, the comprehensive mitigation program (including additional measures for species at risk) is expected to reduce the degree of sensory disturbance to marine mammals. As such, confidence in the significance conclusion is rated as high (Table 7.6.11-4, point 1[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine RSA – loud underwater construction activities at the Westridge Marine Terminal will be detectable beyond the boundaries of the Marine Mammal LSA and may temporarily displace sensitive species such as harbour porpoise from within the LSA; however, effects are not expected to extend beyond the Marine RSA.
- Duration: short-term – while potential effects may extend briefly into the operations phase of the Project, the actual event (*i.e.,* production of loud underwater noise) will be restricted to the construction phase.
- Frequency: isolated – while potential effects may extend briefly into the operations phase of the Project, the actual event (*i.e.,* production of loud underwater noise) will be intermittent throughout the construction phase, but restricted to that phase.
- Reversibility: medium-term – residual effects will occur primarily during the construction phase and are expected to be reversible within a few hours to a few months after the end of construction.
- Magnitude: medium – since mitigation measures will be applied to reduce this potential disturbance to the extent practical, and there is no officially designated critical habitat or DFO Important Areas for marine mammals in the Marine RSA, the magnitude of this effect is determined to be medium.
- Probability: high – it is considered likely that marine mammals in the vicinity of loud underwater construction activities at the Westridge Marine Terminal will experience some degree of sensory disturbance.
- Confidence: high – determination of confidence is based on the engineering assumptions made, the limited number and diversity of marine mammals in the Marine Mammal LSA, and the presumed use of appropriate mitigation measures.

7.6.11.7 Summary

As identified in Table 7.6.11-4, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the marine mammal indicator of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of construction activities at the Westridge Marine Terminal on marine mammals will be not significant.

7.6.12 Marine Birds

Key issues for the marine birds element were identified through discussions with senior regulatory authorities including Environment Canada, and the professional judgment of the assessment team. Project-related issues include:

- a change in habitat quality or availability due to terminal site clearing and construction activities;
- sensory disturbance causing stress or avoidance of marine habitats at or near the Westridge Marine Terminal area due to Project-related activities; and
- injury or mortality due to collisions with terminal or vessel infrastructure, or nest abandonment as a result of sensory disturbances.

The assessment of potential effects to marine birds from the Westridge Marine Terminal expansion has particular objectives which include, but are not limited to, ensuring there is:

- compliance with the BC *Wildlife Act, Migratory Birds Convention Act* (*MBCA*), and other provincial and federal legislative guidelines (Milko 1998, NEB 2013a), with respect to harassment, harm or destruction of nests and nesting birds;
- protection for species at risk, consistent with the objectives of *SARA*, and provincial and local policies related to biodiversity conservation (*e.g.,* provincial Best Management Practices (BMPs) and the BIEAP);
- management of marine bird species within the context of the ecological values in Burrard Inlet; and
- special attention to species of importance to the culture and traditional harvest of Aboriginal communities.

7.6.12.1 Assessment Indicators and Measurement Endpoints

Indicator Species

It is important to consider potential Project-related effects on all marine bird species within the study area; however, it is impractical to assess every species present. A suite of marine bird indicators can be selected to characterize the effects to all bird species, each indicator representing an ecological guild using a similar foraging strategy or ecological niche (Lindenmayer *et al.* 2000). The process for selecting indicators for the assessment of effects to marine birds began with a review of existing marine habitats, consultation with stakeholders and senior authorities, and knowledge of bird species known to be present seasonally in Burrard Inlet. The candidate list of indicators was narrowed by focusing on those species that fit all or most of the following criteria:

- they seasonally utilize habitats within the Marine Birds LSA or Marine RSA for foraging and/or breeding;
- they have life requisites shared by a broad group of other marine bird species;
- they are a species of conservation concern, are considered restricted in range, or associated with a confined or sensitive ecological community;

- there is an established baseline of information on their biology, population abundance and distribution;
- they have been documented as a species susceptible to anthropogenic disturbances;
- they are a species whose extirpation could alter or disrupt the function of the ecosystem;
- they have been identified as important to some coastal Aboriginal communities; and
- they have previously been used as indicators in regional effects-based assessments and, therefore, have been the focus of academic and regulatory studies within the Marine RSA.

Based on these criteria, six indicator species were selected to assess potential effects of the construction and operation of the Westridge Marine Terminal on marine birds: bald eagle (*Haliaeetus leucocephalus*), great blue heron (*Ardea herodias fannini*), pelagic cormorant (*Phalacrocorax pelagicus)*, Barrow's goldeneye *(Bucephala islandica)*, glaucous-winged gull *(Larus glaucescens)* and spotted sandpiper (*Actitis macularius*). These six species represent an overall diverse group of resident and migrant marine bird species that utilize distinct niches within the matrix of marine and coastal habitats present within the Marine Birds LSA and Marine RSA.

The selection of a suite of marine bird indicators was discussed with Environment Canada, more specifically the Canadian Wildlife Service, at a meeting held on April 17, 2013. The final selection of indicators took into consideration feedback from this meeting, input from other regulators, stakeholders, Aboriginal communities, and the professional judgment of the assessment team that have extensive experience on other marine development projects with similar ecological conditions and potential issues. Suggestions provided for the selection of indicators at the ESA Workshops on May 22 and 23, 2013 included marine birds that were species at risk, or uncommon and sensitive, including western grebe, purple martin and marbled murrelet. The judgment of Project assessment team was that these suggested species were too low in abundance or seasonal presence for effective monitoring and that they were adequately represented by the selected indicator species presented here.

The following subsections provide a brief description of biology and relevance of the six marine bird indicator species selected for this assessment. More detailed information on these species and their habitats in the Marine RSA can be found in the Marine Birds – Westridge Marine Terminal Technical Report of Volume 5C.

Bald eagles may be affected by direct alteration or loss of trees for terrestrial perching and nesting habitat, and by sensory disturbances from noise, light and activity associated with the construction and future operations of the Westridge Marine Terminal expansion. These effects may cause them to avoid preferred roosts or feeding sites. There is also minimal potential for injury or mortality to bald eagles during inclement weather as a result of their accidental collision with infrastructure at the terminal, berthed vessels or large construction equipment temporarily present during terminal expansion. The bald eagle is a year-round resident and recent breeding records indicate there are nests at approximately 15 sites within the Marine RSA. The population is stable and abundant in BC. It has similar habitat requirements to other raptor species that occasionally use the marine foreshore and open water areas to fish or scavenge, such as osprey, vulture and Cooper's hawk. It is considered a top predator and local flagship species, having special cultural importance to Aboriginal communities.

Great blue herons may potentially be affected by sensory disturbances caused by noise, light and activity associated with the construction and operation of the expanded Westridge Marine Terminal. Clearing of the foreshore and upland terrestrial vegetation could result in alteration to, or loss of, preferred shoreline foraging sites and tree roosts. Great blue herons are woodland colonial nesters with strong nest site fidelity. Local breeding colonies are located in Stanley Park at the western edge of the Marine RSA and several kilometers upstream of the terminal on Heron Creek, therefore, they are unlikely to seek alternate nest sites within the Project LSA. There is minimal potential for injury or mortality from collisions with large equipment or terminal infrastructure due to disorientation caused by night-lighting, or during periods of low visibility, fog or inclement weather. The great blue heron is a resident species of conservation concern (provincial list status – Blue; federal *SARA* status – Special Concern). Direct threats to local populations include disturbance and mortality from predators and humans, limited food resources, and environmental contamination (COSEWIC 2008f, Vennesland 2004). The great blue heron has similar requirements to other species that rely on intertidal, foreshore and coastal terrestrial habitats, such as sandpipers and kingfishers.

Pelagic cormorants may be disturbed by in-air noise and activity associated with the construction and operation of the Westridge Marine Terminal and Project-related vessel activity. In addition, the cormorant's foraging behaviour of diving within the foreshore areas for small fish may expose them to underwater noise from vessels operating vessels, or loud in-water construction and pile-driving. Although cormorants typically roost in trees, there is a tendency to use artificial structures in developed areas such as cranes, bridges and wharfs. The risk of injury or mortality from bird collisions with infrastructure as a result of night-lighting or low visibility during fog or inclement weather is minimal. Injury could result from their perching or moving within unstable or unfamiliar, large construction equipment present temporarily during terminal expansion. The pelagic cormorant is a resident species and locally breeds at several colonies seasonally active within Burrard Inlet. BC populations are declining and, consequently, the pelagic cormorant is a species of conservation concern (provincial list status – Red). It has similar foraging habitat requirements to other diving piscivorous birds using littoral zones within the Marine RSA, such as the common merganser.

Barrow's goldeneyes may be affected by sensory disturbances resulting from noise and activity associated with the construction and operation of the expanded Westridge Marine Terminal and Project-related vessel activity. Potential injury or mortality could result from collisions with terminal infrastructure if bird become disoriented during night-lighting of the terminal, or during periods of fog or inclement weather, especially during seasonal migrations. The Barrow's goldeneye is a seasonally resident seabird (fall, winter, and early spring) which breeds on inland freshwater lakes. The Inlet provides important staging and overwintering forage and refuge habitat during non-breeding periods (Boyd *et al.* 2011). It has similar requirements to other migrating and resident seabirds and waterfowl that feed on nearshore invertebrates, bivalves and intertidal vegetation. Large flocks of Barrow's goldeneye congregate to forage during winter, often in rafts with other seabird species and, therefore, can be vulnerable to localized environmental effects.

Glaucous-winged gulls have a strong association with urban developed areas, and consequently there is an assumption that they are familiar with structures at this and other local sites, especially if reared in Burrard Inlet. However, under particular circumstances, individuals may be affected by sensory disturbances from noise and activity associated with the construction and operation of the expanded Westridge Marine Terminal and Project-related vessel activity. Injury or mortality from collisions with infrastructure and construction equipment associated with the terminal expansion is possible but unlikely. The glaucous-winged gull is an abundant resident species breeding annually at several colonies within Burrard Inlet. Nesting habitat is typically flat, rocky, or gravel substrates, but also includes human-built structures, and floating platforms along the shore. Within Puget Sound, glaucous-winged gull colonies are most often located in human-altered habitats (Seattle Audubon Society 2013). This species feeds opportunistically on a range of available natural and urban resources and has similar resource and habitat requirements to many marine birds as a generalist adapted to the current context of disturbed environments in the Marine RSA, such as northwestern crows and killdeer.

Spotted sandpipers typically forage along shorelines with other sandpiper and passerine species species, all which tend to flush easily when disrupted by human activity. They may be affected by sensory disturbances from noise and activity associated with the construction and operation of the expanded Westridge Marine Terminal and Project-related vessel activity. Effects from vegetation clearing of the Project footprint may include the alteration or loss of upland shoreline breeding habitat for spotted sandpipers using the security and thermal cover of low shrubs and forbs. Suitable nest sites are typically on shorelines with abundant ground cover and are selected near intertidal shores and mudflats to take advantage of foraging opportunities for invertebrate prey (Seattle Audubon Society 2013). There is a potential for events of injury or mortality from one or more birds colliding with terminal infrastructure as a result of disorientation from terminal night-lighting, or periods of low visibility during fog or inclement weather. The spotted sandpiper is a breeding species and primarily resident; some individuals are migratory. It has similar habitat requirements to other resident and seasonally present shorebirds or passerines that rely on the intertidal and upland coastal terrains for nesting and foraging.

Rationale for the selection of each of the indicators is summarized in Table 7.6.12-1.

Measurement Endpoints

The Project has the potential to affect marine birds through direct change in habitat availability or quality, sensory disturbance, and risk of injury or mortality from Project-related activities. Measurement endpoints (parameters) associated with these effects have been identified for each indicator (Table 7.6.12-1) and include both quantitative and qualitative measurements. The quantitative measurements include the area of suitable foraging or breeding habitat that will be altered or lost as a result of Westridge Marine Terminal clearing and construction calculated from the most current Westridge Marine Terminal engineering and design plans. The effect of sensory disturbance was qualitatively assessed for each indicator species based on potential changes in suitable habitat use, stress, behavioural alterations or habitat avoidance as a result of Terminal construction or operations. The potential for marine bird injury or mortality was qualitatively assessed for each of the indicators based on the known behavioural tendencies during movement or migration, sensitivity to night-lighting of the terminal or berthed vessels, anticipated level of risk or familiarity, and seasonal use of the species relative to the anticipated changes to Westridge Marine Terminal facilities and structures during Project construction and operations. The degree of change in these endpoints was used to characterize, and determine the significance of, potential direct and cumulative environmental effects from the Project on marine birds.

TABLE 7.6.12-1

ASSESSMENT INDICATORS AND MEASUREMENT ENDPOINTS FOR MARINE BIRDS

Marine Bird Indicator	Measurement Endpoints	Rationale for Indicator Selection
Bald eagle	• Quantitative measure of area of coastal habitat altered or lost due to Project activities • Qualitative potential for sensory disturbance from Project activities • Qualitative potential for injury or mortality from collisions with terminal infrastructure	• Breeding resident. • Established baseline of bird biology, population abundance and distribution • Sensitive to anthropogenic changes in habitat. • Top predator, keystone and flagship species. • Culturally important to Aboriginal communities. • Similar requirements to other raptors.
Great blue heron	• Quantitative measure of area of coastal habitat altered or lost due to Project activities • Qualitative potential for sensory disturbance from Project activities • Qualitative potential for injury or mortality from collisions with terminal infrastructure	• Breeding resident. • Species of conservation concern. • Declining in population abundance. • Established baseline of bird biology, population abundance and distribution. • Sensitive to anthropogenic and predator disturbances, and changes in shoreline and forested habitats. • Similar requirements to other foreshore waders.
Pelagic cormorant	• Quantitative measure of area of coastal habitat altered or lost due to Project activities • Qualitative potential for sensory disturbance from Project activities • Qualitative potential for injury or mortality from collisions with terminal infrastructure	• Breeding resident. • Species of conservation concern. • Declining in population abundance. • Established baseline of bird biology, population abundance and distribution. • Sensitive to anthropogenic and eagle disturbances. • Similar requirements to other littoral zone piscivores.
Barrow's goldeneye	• Quantitative measure of area of coastal habitat altered or lost due to Project activities • Qualitative potential for sensory disturbance from Project activities • Qualitative potential for injury or mortality from collisions with terminal infrastructure	• Winter resident, spring/fall migrant. • Congregates in large flocks to feed. • Established baseline of bird biology, population abundance and distribution. • Sensitive to anthropogenic disturbances and habitat alteration. • Similar requirements to other seabirds and waterfowl.
Glaucous-winged gull	• Quantitative measure of area of coastal habitat altered or lost due to Project activities • Qualitative potential for sensory disturbance from Project activities • Qualitative potential for injury or mortality from collisions with terminal infrastructure	• Breeding resident. • Abundant population as a generalist in natural and anthropogenically disturbed environments. • Established baseline of bird biology, population abundance and distribution. • Traditionally important to Aboriginal communities. • Similar requirements to a wide range of marine birds.

TABLE 7.6.12-1 Cont'd

Marine Bird Indicator	Measurement Endpoints	Rationale for Indicator Selection
Spotted sandpiper	• Quantitative measure of area of coastal habitat altered or lost due to Project activities • Qualitative potential for sensory disturbance from Project activities • Qualitative potential for injury or mortality from collisions with terminal infrastructure	• Breeding resident. • Established baseline of bird biology, population abundance and distribution, • Sensitive to anthropogenic disturbances. • Similar requirements to other foraging and nesting shorebirds.

7.6.12.2 Spatial Boundaries

Spatial boundaries for the assessment of potential Project effects on marine birds are defined as follows.

- Project Footprint: the area directly affected by construction of the Westridge Marine Terminal.
- Marine Birds LSA: the ZOI for marine birds likely to be affected by construction and operations of the Westridge Marine Terminal, defined as the area within 300 m of the proposed water lease expansion.
- Marine RSA: the area where the direct and indirect influence of other activities could overlap with Project-specific effects and cause cumulative effects on marine birds. This includes the area of Burrard Inlet east of the First Narrows, including Indian Arm and Port Moody Arm.

This ZOI used to define the Marine Birds LSA is a reasonable estimate of the thresholds of disturbance for sensitive species of marine birds as indicated in scientific literature (Hentze 2006, Ruddock and Whitfield 2007). It is a standard observation distance for marine bird surveys in various sea conditions (Resources Information Standards Committee [RISC] 1997) and has been applied as a threshold of disturbance for marine birds in similar marine projects in BC (*e.g.,* NGPLP 2006) using the professional judgment and expertise of the assessment team.

The spatial extent of the Marine RSA represents a rational balance between a large conservative assessment area where effects may not be detectable and a smaller area where the assessment of effects on populations of special concern may not be biologically meaningful. The Marine RSA is also bounded by developed shorelines which naturally limit the assessment of potential marine effects. There is an abundance of information for this spatial area including local studies, available research literature, and input from regulators.

Study area boundaries for marine birds are shown on Figures 6.2-1 and 6.2-2.

7.6.12.3 Marine Bird Context

The original dock at the Westridge Marine Terminal was constructed in 1957 using wood piles and decking. At that time, the shoreline south and west of the dock was extended seaward using rock and sediment fill. Over the course of the last few decades, the dock has been upgraded several times. The original wood piles have been replaced by steel piles, the wood decking with a steel and concrete trestle and loading platform, and concrete caissons to support the infrastructure. Large rip rap was added to reinforce the infill along the shoreline. As a result of the historic development at the Westridge Marine Terminal, approximately 480 m of the 710 m (68%) of shoreline within the Westridge Marine Terminal water lot has been replaced with fill material. To the east of the trestle, the upper intertidal zone has been infilled to support the CN rail line. The existing Westridge Marine Terminal currently has one loading berth which accommodates one Aframax tanker or barge.

Marine birds require marine and coastal habitats during all or a part of their life cycle (Croxall *et al*. 2012). They are an important component of BC marine ecosystems because of their high abundance and species diversity (Milko *et al*. 2003). This particular group of bird species uses coastal terrestrial habitats (above high-water mark); foreshore (shoreline from high-water to low-water tide mark); nearshore (low-water mark to water extending 10 m seaward); and offshore areas (nearshore to the continental shelf). The BC south coast supports large year-round and seasonal bird populations, often referred to in broad groups: geese and swans; shorebirds; dabbling and diving ducks; gulls, jaegars, skuas and terns; loons and grebes; murres, murrelets, guillemots and auklets; cormorants; kingfishers; wading birds; corvids; and coastal raptors. These groups occur within the Marine RSA. Marine birds are long-lived species, often living more than 20 years (Clapp *et al.* 1982) that produce few offspring, often only one per year, and provide a large amount of parental care compared to most marine species. Therefore, marine bird individuals and populations can, at certain times, be vulnerable and slow to rebound from adverse human and environmental impacts.

Burrard Inlet has been designated within an Important Bird Area (IBA020 - English Bay and Burrard Inlet) by BirdLife International (2013), a partnership of Bird Studies Canada and Nature Canada. Approximately 110 of the 307 species recorded in the IBA across seasons are marine birds and waterfowl (BIEAP 2002). The area attracts tens of thousands of migratory birds using the Pacific Flyway, is globally important habitat for western grebes, Barrow's goldeneye, and surf scoter, and is nationally important habitat for great blue herons (BIEAP 2002, BirdLife International 2013). Bird abundance in the inlet has been recorded at more than 24,000 birds during peak spring months (BIEAP 2002, Breault and Watts 1996). The marine areas of Central Harbour have the greatest abundance of waterbirds recorded here. The highest diversity of non-waterfowl marine birds (9 to 11 species) have been recorded near Port Moody, First Narrows Bridge and Second Narrows Bridge (Breault and Watts 1996).

The Marine RSA contains approximately 17 bird breeding colonies of 5 species; glaucous-winged gulls, pelagic cormorant, pigeon guillemot, great blue heron and purple martin (see Marine Birds – Westridge Marine Terminal Technical Report of Volume 5C for details and locations), and 25 species of conservation concern with seasonally required foraging, nesting and moulting habitats. Many of those species have been documented as sensitive to disturbance to varying degrees. The south coast, including Burrard Inlet and associated watercourses, are an important movement corridor and staging area for, often millions of, migrating birds, especially shorebirds and waterfowl (Butler 1992, Collins *et al*. 2011, Donaldson *et al*. 2000).

In terms of marine species, seabirds offer many advantages for study. They are highly visible and easily enumerated as they travel and forage in marine areas where most other plants and animals are underwater. Most are colonial and congregate annually in large numbers at relatively few locations to reproduce and forage. This allows the measurement and monitoring of population, distribution and behavioural parameters. Some species tend to travel or forage at night. Many species groups tend to particularly vulnerable to human activity and development. For these reasons, marine birds are frequently identified as useful indicators of marine-ecosystem health (Croxall *et al*. 2012, Mallory *et al*. 2010, Parrish *et al*. 2007, Piatt *et al*. 2007).

7.6.12.4 Potential Effects and Mitigation Measures

The Westridge Marine Terminal construction and operations activities are anticipated to have the potential to adversely affect marine birds through changes in habitat, sensory disturbance and risk of injury or mortality during the construction and operational phases of the Project. Environmental effects to marine birds are assessed within the context of habitat presently available within the Marine Birds LSA prior to construction (*i.e.,* existing conditions) which will change during and after construction.

Identified Potential Effects

Potential effects associated with construction and operations of the Westridge Marine Terminal on marine bird indicators are listed in Table 7.6.12-2. These effects were identified through a literature review, field studies, desktop analyses and the professional expertise and experience of the assessment team. Consultation with senior regulatory authorities (primarily Environment Canada) and other relevant stakeholders provided additional information on potential effects and mitigation measures.

Change in Habitat Quality or Availability

Change in habitat quality or availability can occur from land clearing, siltation during dredging, construction and temporary structures. Clearing for additional terminal infrastructure and buildings will include 2,685 m^2 (0.27 ha) of marine riparian habitat that will not be available for the operational life of the Westridge Marine Terminal. Removal of any large trees or shrub habitat could adversely affect nesting opportunities for bald eagle, great blue heron and spotted sandpiper. Anticipated minor changes in foreshore and shoreline habitats may affect preferred habitats used by marine birds to forage, roost/perch and nest. Construction activities could result in a temporary reduction in littoral-benthic zones available for foraging seabirds, although, there are abundant sites in adjacent channels and bays. After construction and during operations; however, new terminal and berth structures could provide roosting sites for some species, such as eagles, cormorants and herons. The degree to which each species may be affected depends on the type and amount of landscape and structures altered, seasonal species-specific use, the known sensitivities and vulnerabilities of these species, and the adaptability of some species to altered habitats.

Sensory Disturbance

The highest sound level due to terrestrial construction activities at the closest affected human receptor was predicted by noise modelling (Section 7.6.6 Acoustic Environment) to be approximately 70 dBA; however, detailed construction planning required to fully assess urban sound levels is not available at this stage of project planning. Noise levels as a result of night time construction, in-water dredging and pile driving have not yet been assessed; however, potentially high magnitude sound levels could be mitigated with additional noise management planning. During operations the spatial extent of the operating sounds (*e.g.,* pumps, ship loading, ship berthing and support equipment, ship idling at the berth, and tug operations) are expected to be limited to the Marine Birds LSA. The predicted sound levels created by the terminal, including the proposed expansion operations, is approximately 49 dBA at the nearest homes west of the site, and during the more stringent nighttime period. The duration of the terminal sound is long-term for the operational life of the Westridge Marine Terminal with a continuous frequency, because the Westridge terminal will operate 24 hours per day, 7 days per week. The effects will be reversible after terminal decommissioning.

Sensory disturbances to marine birds are associated with in-air and underwater noise and activities during Westridge Marine Terminal construction and operational activities. In-air noise and human activities during site clearing, in-air and underwater noise during dredging and pile driving, and an increase in noise and activity during Westridge Marine Terminal operations, could result in the alteration of normal dispersal patterns to avoid these foreshore sites near the Westridge Marine. High magnitude noise levels, such as during impact pile driving, could result in flushing behaviour, individual distress and avoidance from important habitats (*i.e.,* reduced habitat effectiveness). Previous research indicates that birds are disturbed by in-air noise levels greater than 90 dBA (90 dB re: 20 µPa) (Gladwin *et al.* 1988). Given the context of industrial activity and marine vessel traffic in Burrard Inlet, marine birds may habituate to operational and low level construction noise, and other types of sensory disturbances, that are predictable and not associated with negative consequences (Grubb *et al*. 2002, Steidl and Anthony 2000, Ward and Stehn 1989). Although known to be sensitive to human disturbance (Smith 2000), there are no studies from the local area to determine the extent of habituation or effects; however, it would be difficult to separate effects related directly to Project activities from the effects of other human activities in the Inlet.

Sources of underwater noise disturbance are pile-driving, and to a lesser degree, dredging, during terminal construction. Engineering information regarding the type and method of pile-driving, and the method and extent of dredging, that will be used for expansion of the Westridge Marine Terminal were not available at the time of this assessment. However, detailed assumptions and literature-sourced data on various types, sizes and methods, with resulting noise assessments, have been provided for marine mammals in Section 7.6.11.4. In this subsection, impact dredging is reported to have a potential broadband source level (peak SPL) of 187 dB re: 1 µPa at 1 m, and a clamshell dredge has a maximum broadband source level of approximately 167 dB re: 1 µPa at 1 m (Richardson *et al*. 1995). Vibratory drivers produce less noise impact, approximately 25 dB lower than that of impact driving. Guidance from the Project engineers to date has indicated that pile driving is to be conducted irregularly but relatively consistently over a period of approximately 2 years. Therefore, with regard to mitigating effects to marine wildlife, vibratory drivers are the preferred method of pile driving. Only a small amount of dredging will likely be required (*i.e.,* approximately 60 days) using a clamshell dredge.

Although there is considerable information on noise disturbance to marine mammals, little information is available on the hearing capabilities and thresholds of disturbance of birds underwater. The harm from, or avoidance of, events of underwater noise could adversely affect feeding effectiveness, nest provisioning, or the energetics critical to staging and migration periods. Variation in response to disturbance events is associated with the level of source-noise to that of the ambient, degree of naiveté of the animals to the source-noise, ongoing activity at the time of exposure and, to an uncertain degree, the species involved (Myrberg 1990). The most recent information is from a study of the hearing of the Blackfooted penguin (*Sphenikcus demersus*), the results of which indicate an underwater sensitivity measured at 1-4 kHz (McCauley and Salgado Kent 2008). Although there is no formal guidance on the assessment of disturbance to birds from underwater noise, there are general principles that can be used to indicate the potential for a level of disturbance, Nedwell *et al.* (2004) suggest that a behavioural response in a marine bird on the surface would be elicited if the in-air noise level was greater than 90 dB re: 20 µPa. At this noise level, individuals have been found to show an avoidance reaction, typically swimming away from the source of noise. Using guidance provided in Slabberkoorn *et al*. (2010), an airborne sound pressure level of 90 dB re: 20 µPa is comparable to an underwater 151.5 dB re: 1 µPa, with sound level adjustments for the higher acoustic impedance in water, and that sound travels much greater distances at higher amplitude levels in water. During impact piling installation, noise levels 187 dB re: 1 µPa could be reached and; therefore, diving birds in proximity to the in-water construction could be disturbed. Without local baseline studies, the threshold of underwater noise disturbance for particular bird species it is difficult to assess; however, it is reasonable to assume that marine birds, specifically diving species, could be disturbed during loud underwater construction events.

Potentially high suspended sediment levels may affect marine bird visibility of prey and the abundance of food immediately around the construction site; however, this would be a temporary condition. Construction of the new berths have the potential for minimal adverse effects to water quality, visual acuity and prey availability in foreshore or intertidal areas to foraging marine birds. Operations are less likely to have substantial effects on marine birds considering the context of high vessel activity and adjacent industry within their current habitats.

Injury or Mortality

Injury or mortality may occur as a result of pre-construction activities to remove marine riparian substrates and vegetation. If it were necessary to clear vegetation at the shoreline during the breeding season, there is the potential to accidentally injure or kill ground and shrub nesting birds, eggs and nestlings. Substantial sensory disturbance events, such as unusual human activity or persistent loud noises could, in some cases, cause nest abandonment and the consequent mortality of exposed young nestlings.

Mortality may occur during rare events of birds colliding with Westridge Marine Terminal or vessel infrastructures, large construction-related equipment or motorized vehicles, primarily as a result of disorientation by night lighting of the Westridge Marine Terminal area or lack of visibility during weather events. Major sources of artificial light in the marine environment include vessels, marine terminals, and local shoreline industry and developments. Seabirds are highly visually oriented and known to become disoriented at night, especially during migration, in the presence of artificial light (Bruderer *et al*. 1999, LeCorre *et al*. 2002). Night lighting of the Westridge Marine Terminal or docked vessels can attract some species groups that are more responsive to or confused by night-lights and susceptible to collisions with terminal structures. The risk of injury or mortality increases when visibility is reduced during inclement weather (Greer 2010, BirdLife International 2003). Variables that influence the level of risk include weather conditions, season, species, age of birds, and the lunar phase (Montevecchi 2006). Bird strikes or collisions have been documented at various shipping areas around the world (Black 2005, Merkel and Johansen 2011, Montevecchi 2006). The Westridge Marine Terminal expansion will require a marginal increase in lighting from existing light levels which could result in rare collision events. Resident birds may be acclimated to night-lighting at this and proximal locations and information on bird strikes is lacking for the Marine RSA. Consequently, no specific thresholds for evaluation of this effect have been identified.

A summary of mitigation measures provided in Table 7.6.12-2 was principally developed in accordance with the professional experience of the assessment team, as well as applicable measures in accordance with Trans Mountain professional operating standards.

TABLE 7.6.12-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON MARINE BIRDS

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Marine Bird Indicator – Bald Eagle			
1.1 Change in habitat quality or availability	LSA	• Adhere to an established Environmental Protection Plan (EPP) and monitor in an adaptive framework. • Confine all clearing and associated activities within the staked/flagged Westridge Marine Terminal construction boundaries. Adhere to clearing restrictions associated with special environmental features (*i.e.,* nesting birds) as outlined in the Wildlife and Wildlife Habitat Specific Protection and Management Measures table [Section 8.1]. • Ensure that any potential mitigation measures concerning marine wildlife species at risk are communicated to the Contractor and enforced by the Lead Activity Inspector and the Environmental Inspector [Section 8.1]. • Clear shrubs with limited habitat potential within the appropriate timing windows for breeding birds to discourage nesting on the Westridge Marine Terminal site prior to construction, if construction is scheduled to occur during the spring/summer period [Section 8.1]. • Direct that a breeding bird nest survey be conducted by a qualified marine avian biologist at least seven days prior to initiating activities in areas where clearing activities have not been completed prior to the start of the bird nesting period. In the event that a nest is discovered, or found incidentally during other Project-related activities, an appropriate mitigation strategy will be established by Trans Mountain's Environmental Inspector or Wildlife Resources Specialists as described in the Onshore or Marine Wildlife Species of Concern Discovery Contingency Plan [Section 8.1]. • The Environmental Inspector will ensure the brushing Contractor clears shrubby vegetation from the Westridge Marine Terminal prior to the onset of the bird nesting season. See the Environmental Facility Drawings of Westridge Marine Terminal for locations to be pre-cleared. Any clearing within the migratory restricted activity period (RAP) will only be allowed if a nest survey has been conducted within seven days of the commencement of clearing and no nesting activity was observed [Section 8.1]. • Apply species-specific buffers, provided by wildlife resource specialists, at all active bird nest sites [Section 8.1]. • Install sediment fences at the base of cut/fill areas to reduce sediment discharge into the marine environment, where warranted [Section 8.1]. • Maintain sediment fences in place at the base of cut/fill areas, where warranted, until revegetation is stable [Section 8.1]. • Ensure that watering of roads and work surfaces does not generate excessive formation of surface water accumulation (*i.e.* puddles or excessive mud generation), or result in overland water flow or sedimentation of the marine environment. [Section 8.1]. • Implement appropriate marine sediment/turbidity control measures within the surrounding area, prior to marine construction activities, to contain sedimentation to the marine work area (*e.g.,* turbidity curtains) [Section 8.2].	• Loss of foraging, nesting and roosting habitat, which may adversely affect species fitness and population sustainability.

TABLE 7.6.12-2 Cont'd

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1.2 Sensory disturbance	RSA	• Initiate pre-construction environmental monitoring, where warranted, prior to the commencement of construction or, if appropriate, prior to the commencement of a specific activity (*e.g.*, pile installation). At some locations, monitoring will be necessary to assess the effects on specific environmental features (*e.g.,* nesting birds). If, required, ensure that applicable permits/approvals/authorizations are in place to allow monitoring to be conducted [Section 6.0]. • Noise abatement and construction scheduling will be considered during noise-sensitive periods, to limit disruption to sensitive receptors (*e.g.,* nesting birds) [Section 7.0]. • Prevent sky-lighting which may lead to bird disorientation/collisions, where feasible, by: using low level and low intensity lighting; using no lighting in areas where no work is planned; using downturned shaded fixtures in light standards; and using a higher lumen/watt (light out to power in) ratio, such as metal halide lighting [Section 7.0]. • Operate all Project-related vessels at slow speeds during marine construction in order to limit the intensity of acoustic emissions. Vessel operators will avoid rapid acceleration to control noise [Section 8.2]. • Propellers of all Project-related vessels will be well maintained in order to reduce underwater noise [Section 8,2]. • Use a vibratory method of pile installation instead of an impact hammer, if feasible [Section 8.2] • Deploy bubble curtains during pile installation to reduce underwater noise levels where an impact hammer is required for pile installation [Section 8.1].	• Stress, behavioural changes or avoidance of preferred or important habitats, which may adversely affect species fitness and population sustainability.
1.3 Injury or mortality	RSA	• Prevent sky-lighting which may lead to bird disorientation/collisions, where feasible, by: using low level and low intensity lighting; using no lighting in areas where no work is planned; using downturned shaded fixtures in light standards; and using a higher lumen/watt (light out to power in) ratio, such as metal halide lighting [Section 7.0]. • During migratory bird periods and/or during extreme weather events, bird strike warnings will be issued to berthed vessels with a request to reduce deck lighting [Section 7.0]. • Inform all operators of Project-related vessels of the hazards regarding bird strikes occurring at night because of deck lighting or inclement weather and bird collisions with Westridge Marine Terminal structures. Report all bird strikes/collisions immediately to Trans Mountain's Lead Activity Inspector and the Environmental Inspector Section 8.2]. • Ensure construction activities located within offshore or marine wildlife setback distances will be scheduled to occur within least risk windows or proceed with the approval of the appropriate regulatory authority [Section 7.0]. • Implement the Onshore or Marine Wildlife Species of Concern Discovery Contingency Plan in the event that potentially rare and endangered wildlife species and/or their habitats are discovered during construction [Section 8.0]. •	• Injury or mortality events, which may adversely affect population abundance.
2. Marine Bird Indicators – Great Blue Heron			
2.1 Change in habitat quality or availability	Footprint	• See recommended mitigation measures from potential effect 1.1 of this table.	• Loss of foraging, nesting and roosting habitat, which may adversely affect species fitness and population sustainability.
2.2 Sensory disturbance	RSA	• See recommended mitigation measures from potential effect 1.2 of this table.	• Stress, behavioural changes or avoidance of preferred or important habitats, which may adversely affect species fitness and population sustainability.
2.3 Injury or mortality	RSA	• See recommended mitigation measures from potential effect 1.3 of this table.	• Injury or mortality events, which may adversely affect population abundance.

TABLE 7.6.12-2 Cont'd

Potential Effect	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
3. Marine Bird Indicators – Pelagic Cormorant			
3.1 Change in habitat quality or availability	LSA	• See recommended mitigation measures from potential effect 1.1 of this table.	• Loss of foraging, nesting and roosting habitat, which may adversely affect species fitness and population sustainability.
3.2 Sensory disturbance	RSA	• See recommended mitigation measures from potential effect 1.2 of this table.	• Stress, behavioural changes or avoidance of preferred or important habitats, which may adversely affect species fitness and population sustainability.
3.3 Injury or mortality	RSA	• See recommended mitigation measures from potential effect 1.3 of this table.	• Injury or mortality events, which may adversely affect population abundance.
4. Marine Bird Indicators – Barrow's Goldeneye

6.1 Change in habitat quality or availability	Footprint	• See recommended mitigation measures from potential effect 1.1 of this table.	• Loss of foraging, nesting and roosting habitat, which may adversely affect species fitness and population sustainability.
6.2 Sensory disturbance	RSA	• See recommended mitigation measures from potential effect 1.2 of this table.	• Stress, behavioural changes or avoidance of preferred or important habitats, which may adversely affect species fitness and population sustainability.
6.3 Injury or mortality	RSA	• See recommended mitigation measures from potential effect 1.3 of this table.	• Injury or mortality events, which may adversely affect population abundance.

Notes: 1 LSA = Marine Birds LSA; RSA = Marine RSA.
2 Detailed mitigation measures are provided in the Westridge Marine Terminal EPP (Volume 6D).

7.6.12.5 Potential Residual Effects

The potential residual environmental effects on the marine bird indicators associated with construction and operations activities at the Westridge Marine Terminal (Table 7.6.12-2) are:

- alteration or loss or of foraging, nesting and roosting habitat, which may adversely affect species habitat effectiveness, altered energy budgets, reduced individual fitness, or effects to the abundance of local breeding populations;
- sensory disturbances causing stress, behavioural changes or avoidance of preferred or important habitats, which may adversely affect individual fitness and local population sustainability; and
- events of accidental injury or mortality, which may adversely affect local population abundance.

7.6.12.6 Significance Evaluation of Potential Residual Effects

The significance of the effects from habitat loss were assessed quantitatively as changes to the baseline data from proposed clearing limits at the shoreline of the terminal and the area of marine disturbance from construction of additional berths. A qualitative assessment was the most appropriate approach to evaluate the significance of the potential residual effects of disturbance and injury or mortality due to a lack of scientific and regulatory thresholds to define rating criteria for marine bird indicators. The evaluation of significance of these potential residual effects relied on recent available research literature for other areas or marine species, many years of related field experience, and the professional expertise and judgment of the marine environmental assessment team.

Table 7.6.12-3 provides a summary of the significance evaluation of potential residual effects on marine bird indicators from construction and operation of the expanded Westridge Marine Terminal. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.6.12-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CONSTRUCTION AND OPERATIONS AT THE WESTRIDGE MARINE TERMINAL ON MARINE BIRDS

				Temporal Context						
	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Duration	Frequency	Reversibility	Magnitude	Probability	Confidence	Significance[2]

Notes: 1 LSA = Marine Birds LSA; RSA = Marine RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Marine Birds Indicator – Bald Eagle

The following subsections provide the evaluation of significance of potential residual effects on the bald eagle indicator.

Loss or Alteration of Foraging, Nesting and Roosting Habitat

There will be 2,685 m^2 (0.27 ha) of marine shoreline and riparian habitat lost due to Westridge Marine Terminal construction, a portion of which is suitable bald eagle habitat (Anthony *et al.* 1982). This may adversely affect the availability of raptor nesting, perching or foraging habitat in the Marine Birds LSA. Bald eagle predation is opportunistic and occurs in shallow aquatic zones or shorelines. They feed primarily on live and dead fish, ducks and other waterbirds, and small mammals. Large stick nests are built and used year after year in tall trees or on cliffs. Historic bald eagle nesting sites are at approximately 15 locations throughout the Marine RSA, with consideration for their tendency to build one or two alternate nests at different sites within their breeding range (Cook 2008). The Marine Birds LSA has limited value as foraging and nesting habitat for this species due to existing terrestrial disturbance and terminal activities; however, the Marine RSA offers other opportunities for these requirements which could potentially offset any effects from terminal expansion. After construction and during operations; vegetation in some perimeter areas of the site will be allowed to recover and regrowth could provide perching or nesting sites. The bald eagle represents other raptor species which may also be using these shoreline and foreshore habitats and this recovery is true for other tree-dwelling marine bird species as well, such as osprey, cormorants and herons. The existing Westridge Marine Terminal pilings and berth that provide roosting habitat for these species will be removed; however, the additional larger berths may enhance the availability of roosting opportunities. Therefore, the magnitude of the effect of lost or altered perching/roosting or nesting habitat is low, and the reversibility is anticipated to be medium-term in view of the length of time it will take to recovery tree canopy where it might have previously provided suitable habitat (Table 7.6.12-3, point 1[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds LSA – effects are confined to the area of ground disturbance and construction directly associated with the terminal Footprint and potentially includes intertidal zones and shorelines within a portion of the Marine Birds LSA.
- Duration: short-term – the events that will result in habitat loss or alteration will occur during the construction phase of the Project.
- Frequency: isolated – the events causing habitat loss or alteration is confined to the construction phase of the Project.
- Reversibility: medium-term – some cleared areas with associated bald eagle capability habitat are expected to recover in less than 10 years providing opportunities for future habitat use.
- Magnitude: low – effects will be detectable in the short-term but suitable tree cover will recover over time post-construction, and may potentially be enhanced by additional roosting sites provided by terminal infrastructure.
- Probability: high – the Project is likely to alter or destroy suitable bald eagle roosting or nesting habitat during construction.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and bald eagles, and data pertinent to the Project area.

Sensory Disturbance Causing Stress, Behavioural Changes or Avoidance of Important Habitats

Temporary sediment releases in marine waters surrounding the in-water construction sites could alter prey abundance or impede prey visibility. Increased in-air noise and activity at the Westridge Marine Terminal may result in the stress of individuals using preferred and/or important habitats or, alternatively, an alteration of normal movement patterns through avoidance of those preferred foreshore and shoreline areas. Substantial noise levels during construction, dredging and pile driving are expected to have some detectable effect on adult eagles with territories that overlap with the Marine Birds LSA and Marine RSA.

Bald eagles are known to habituate to noise and human activity in developed areas (Grubb *et al.* 2002, McGarigal *et al*. 1991); however, this is difficult to assess. It is reasonable to assume bald eagle persistence is related to some level of anthropogenic tolerance, and this can be said for other raptor or foreshore species that the bald eagle, as an indicator, is representative of, such as vultures, osprey, Cooper's hawk, owls, or great blue herons. Although constraints to obtaining life history requirements can adversely affect habitat effectiveness and individual fitness, the local bald eagle population sustainability is unlikely to be affected assuming some habituation by bald eagles within the context of dense marine activity within the Marine Birds LSA and Marine RSA where many breeding pairs currently reside. The magnitude of the effect of sensory disturbance is anticipated to be low acting periodically over the life of terminal operations (Table 7.6.12-3, point 1[b]); however, reversibility after each event will be short-term. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects may extend into the Marine RSA and beyond the ZOI specific to the visual and noise disturbance threshold of the bald eagle (approximately 200 m).
- Duration: long-term – the events causing sensory disturbances to bald eagles will be initiated during construction and extend throughout terminal operations for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing a sensory disturbance effects will occur intermittently but repeatedly for the operational life of the Westridge Marine Terminal.
- Reversibility: short-term – although bald eagles may habituate to a particular level of noise and human activity from temporary construction and long-term operations of the terminal, recovery from the effects of some disturbance events may be interrupted by subsequent marine activities.
- Magnitude: low – effects will be detectable at the individual level but will not likely be detectable at the population level with consideration for the context of abundant industrial development and activity in the Marine RSA and the potential for some level of individual habituation to disturbance.
- Probability: high – the effect of Project–related sensory disturbances to bald eagles is likely to occur.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and bald eagles, and data relevant to the Marine RSA.

Events of Accidental Injury or Mortality

Bald eagles could potentially be injured or suffer mortality from colliding with vessel or terminal infrastructure while in flight, or if they are perched on moving or unstable equipment. This is most likely to occur if birds are flying through fog or bad weather; however, these events would be accidental and rarely occurring (Table 7.6.12-3, point 1[c]) for adults that have resided long-term in the area of Burrard Inlet. The incremental change in structure and equipment that will occur during and after the construction of the Westridge Marine Terminal should not impose a substantial risk since it is reasonable to assume that there is some familiarity with existing opportunities to perch on similar structures at and around this site. Because bald eagles are known to habituate to human activity, they may return to favoured roosts at or near the terminal within a short time after construction. Long periods of relatively loud noise associated with pile installation could potentially cause sufficient stress to cause nest abandonment, if a nest was near enough to the Westridge Marine Terminal (approximately 200 m) but had not been detected by Inspectors (Volume 6D, Westridge Marine Terminal EPP). Abandonment would result in subsequent mortality of eggs or hatchlings from exposure. The probability of this effect occurring is low considering presence of Environmental Inspectors during construction and that bald eagles currently nest near many commercial and industrial areas in Burrard Inlet. The effect to individuals would be accidental and of low magnitude. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects could extend to outside the direct area of disturbance from construction and operational facilities associated with the terminal expansion.

- Duration: long-term – the effect of bird injury or mortality from collisions with terminal infrastructure could occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal. The effect of bird mortality from nest abandonment would be limited to the construction phase.
- Frequency: accidental – the events causing potential injury or mortality to bald eagles would occur rarely over the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – each event of mortality would be restored within one generation of breeding and maturity of an individual.
- Magnitude: low – effects from rare events will be detectable at the individual level but with mitigation are unlikely to be detectable at the population level.
- Probability: low – mortality would be a rare event and unlikely to occur as a result of the Project.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and bald eagles, and data relevant to the Marine RSA.

Combined Effects on Bald Eagle

Combined effects consider those residual effects that are likely to occur (*i.e.,* habitat loss and sensory disturbance) which, in this section, applies to all indicators. No nests are currently active within or adjacent to the Westridge Marine Terminal and abundant shoreline habitat is available within the Marine RSA for foraging and perching. A comprehensive Westridge Marine Terminal EPP (Volume 6D) has been developed to reduce or eliminate potential harm to marine life during construction of the Westridge Marine Terminal, to include noise baffles, bubble curtains and working windows (September 1 to January 31) that consider sensitive breeding (February 1 to August 31 during 2 years of construction) and bird migration periods. The likelihood of noise levels capable of sensory disturbance events will decrease with distance from the source, for example, noise during construction within the terminal footprint or during in-water pile driving. The effects of noise and activity are not expected to extend beyond the Marine Birds LSA under most construction and operating conditions but may occur intermittently during this period when particular activities are scheduled to occur. To be exposed to sound levels capable of causing disturbance or harm, marine birds would need to be in relatively close proximity to the upland terminal and in-water pile-driving. At the time of this assessment, detailed engineering and parameters of noise and activity associated with pile-driving were not available. However, Trans Mountain will comply with mitigation set out in the Westridge Marine Terminal EPP (Volume 6D), which may be technically supplemented, depending on the conditions at the time, to avoid harm or disturbance to marine life. A summary of the rationale for all of the significance criteria for combined effects on bald eagle is provided below (Table 7.6.12-3, point 1[c]).

- Spatial Boundary: Marine Birds RSA – combined effects from construction and operations could potentially occur within all spatial scales of the assessment area.
- Duration: long-term – the events causing combined effects on bald eagles may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing the combined effects on bald eagles have the potential to occur intermittently but repeatedly over the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – potential combined effects of sensory disturbance, and habitat alteration or loss are expected to recover in less than 10 years.
- Magnitude: low – effects will be detectable at the individual level but are unlikely to be detectable at the population level.
- Probability: high – combined effects on the bald eagle arising from the Project are likely to occur.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and the bird indicator species, bald eagle.

Marine Bird Indicator – Great Blue Heron

The following subsections provide the evaluation of significance of potential residual effects on the great blue heron indicator.

Loss or Alteration of Foraging, Nesting and Roosting Habitat

Effects to great blue herons are expected to be associated with the potential loss or alteration of nesting/roosting and foraging habitat in the Marine Birds LSA. There will be 2,685 m^2 (0.27 ha) of marine riparian habitat lost due to terminal construction, a portion of which is suitable great blue heron habitat. Foraging by great blue herons is opportunistic with regard to what prey is available and is primarily focused within the littoral-benthic zone (COSEWIC 2008f). The indicator, great blue heron forages opportunistically on fish, amphibians, small mammal and invertebrate prey primarily taken at shorelines and within the intertidal zone and, as such, represent the many species of intertidal foragers that occur within the Marine RSA (*e.g.,* sandpiper species, waterfowl species, common raven, migrating birds). Herons nest colonially in woodland forest. The Marine Birds LSA has limited value as foraging and nesting habitat for this species; however, the Marine Birds RSA does offer those opportunities. Stanley Park, which extends to the shoreline in the RSA has an active great blue heron nesting colony and a small colony of a few breeding pairs is located upstream of the Terminal site in the riparian zone of Heron Creek. Herons have strong nest site fidelity and established sites within Burrard Inlet are likely to remain viable. Therefore, the magnitude of effect from loss of nesting and foraging habitat is low (Table 7.6.12-3, point 2[a]). After construction and during operations; vegetation in some perimeter areas of the site will be allowed to recover and new structures could provide roosting or nesting sites for some species, such as eagles, cormorants and herons. The existing Westridge Marine Terminal pilings and berth that currently provide roosting habitat will be removed; however, the additional larger berths may provide enhanced roosting opportunities. Therefore, the reversibility of habitat lost or disturbed is anticipated to be medium-term. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – effects are confined to the area of disturbance and construction associated with the terminal expansion.
- Duration: short-term – the event causing habitat alteration or loss will occur during the construction phase.
- Frequency: isolated – the event causing habitat alteration or loss is confined to the construction phase of the Project.
- Reversibility: medium-term – suitable tree roosting habitat is expected to recover in less than 10 years along with the associated habitat use by great blue herons.
- Magnitude: low – effects will be detectable in the short-term but will begin to recover and potentially be enhanced post-construction with the additional structure provided by new berths.
- Probability: high – the Project is likely to alter foreshore habitat during construction.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and great blue heron, and data specific to the Marine RSA.

Sensory Disturbance Causing Stress, Behavioural Changes or Avoidance of Important Habitats

Increased in-air noise and activity at the Westridge Marine Terminal may result in the stress of individuals (Gebauer and Moul 2001, Vennesland 2000) using preferred and/or important habitats or, alternatively, an alteration of normal movement patterns to avoid those preferred but active foreshore areas. Substantial noise levels during dredging and pile-driving are expected to have some measureable effect on herons. Temporary sediment releases in marine waters surrounding the in-water construction sites could alter prey abundance or impede bird visibility while attempting to catch prey. Constraints from obtaining life history requirements can adversely affect habitat effectiveness, individual fitness and population sustainability. Although, habituation is known to occur in some population groups (Vennesland 2000) depending on local conditions; this is difficult to assess. With consideration for the context of existing high-volume marine traffic and local industry, the magnitude of the effect of disturbance is anticipated to be medium but long-term acting periodically over the life of terminal operations (Table 7.6.12-3, point 2[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects may extend into the Marine RSA and beyond the ZOI specific to the visual and noise disturbance threshold (approximately 200 m) of the great blue heron.
- Duration: long-term – the events causing sensory disturbance will be initiated during construction and extend throughout operations for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing sensory disturbance (*i.e.,* noise and activity during construction and operations) will occur intermittently but repeatedly for the operational life of the Westridge Marine Terminal.
- Reversibility: short-term – although great blue herons may habituate to a particular level of noise and human activity from temporary construction and long-term operation of the terminal, recovery from the effects from some disturbance events may be interrupted by subsequent marine activity.
- Magnitude: medium – effects will be detectable at the individual level but with mitigation may not be detectable at the population level with consideration for the known sensitivities of this species to disturbance.
- Probability: high – the Project is likely to cause sensory disturbances to great blue heron.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and great blue herons, and data relevant to the Marine RSA.

Events of Accidental Injury or Mortality

Great blue herons could potentially collide in flight, or be injured, by vessel or terminal infrastructure if they are perched and it is moving, or unstable, or in they are flying through bad weather; however, these events would be accidental and rare (Table 7.6.12-3, point 2[c]) for adults that have resided long-term in the area of Burrard Inlet. The incremental change in structure and equipment that will occur during and after the construction and expansion of the Westridge Marine Terminal expansion should not impose a safety threat since it is reasonable to assume that there is some familiarity with the existing opportunities to perch on similar structures at and around this site. Relatively long periods of sensory disturbances from noise levels during pile installation could potentially cause adult herons to abandon nests, if a nest was near enough to the terminal, and had not been observed by Inspectors (Volume 6D, Westridge Marine Terminal EPP). This would result in the subsequent mortality of eggs or hatchlings. However, the probability of this effect occurring is low considering the current established nest sites in Burrard Inlet, nest site fidelity, and the presence of Inspectors during construction. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects could extend to outside the direct area of disturbance from construction and operational facilities associated with the terminal expansion.
- Duration: long-term – the effect of bird injury or mortality from collisions with terminal infrastructure could occur during construction and throughout the operational phase for the operational life of the Westridge Marine Terminal. The effect of bird mortality from nest abandonment would be limited to the construction phase.
- Frequency: accidental – effects have the potential to occur rarely and accidentally for the operational life of the Westridge Marine Terminal.
- Reversibility: medium term – each event of mortality would be restored within one generation of breeding and maturity of an individual.

- Magnitude: low – effects from rare events will be detectable at the individual level but if mitigated are unlikely to be detectable at the population level.
- Probability: low – mortality is possible but will be rare and unlikely to occur as a result of the Project.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and great blue herons.

Combined Effects on Great Blue Heron

No great blue heron nests are currently active within or adjacent to the Westridge Marine Terminal and abundant shoreline is available within the Marine RSA for foraging and perching. A comprehensive environmental protection program has been developed to reduce or eliminate potential harm to marine life during construction of the terminal, to include noise baffles, bubble curtains and timing windows that consider sensitive wildlife periods (Westridge Marine Terminal EPP of Volume 6D). The likelihood of noise levels capable of causing disturbances will decrease with distance from the source (*e.g.,* during construction or in-water pile driving). Noise and activity are not expected be substantial to any extent beyond the Marine Bird LSA. To be exposed to sound levels capable of causing disturbance or harm, marine birds would need to be in close proximity to the site of the upland terminal and in-water pile-driving. At the time of this assessment, detailed engineering and parameters of noise and activity associated with pile-driving were not available. However, Trans Mountain will comply with mitigation measures set out in the Westridge Marine Terminal EPP (Volume 6D). A summary of the rationale for all of the significance criteria for combined effects on great blue heron is provided below (Table 7.6.12-3, point 2[d]).

- Spatial Boundary: Marine Birds RSA – combined effects from construction and operations could potentially occur within all spatial scales of the assessment area.
- Duration: long-term – the events causing combined effects on great blue heron may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing combined effects have the potential to occur intermittently but repeatedly for the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – potential combined effects of sensory disturbance, and habitat alteration or loss are expected to recover in less than 10 years.
- Magnitude: low – effects will be detectable at the individual level but are unlikely to be detectable at the population level.
- Probability: high – the combined effects on the great blue heron arising from the Project are likely to occur.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and great blue herons, and data relevant to the Marine RSA.

Marine Bird Indicator – Pelagic Cormorant

The following subsections provide the evaluation of significance of potential residual effects on the pelagic cormorant indicator.

Loss or Alteration of Foraging, Nesting and Roosting Habitat

Effects to pelagic cormorants are expected to be associated with the potential loss or alteration of nesting/roosting and foraging habitat in the Marine Birds LSA. Several breeding colonies are located within the Marine RSA on rocky islets and bridge structures (Moul and Gebauer 2002). Cormorants often roost in large trees and on boulder substrate in more natural shoreline habitats. There will be 2,685 m^2 (0.27 ha) of marine riparian habitat lost due to terminal construction, a marginal portion of which is suitable cormorant perching and preening habitat. Pelagic cormorants are opportunistic foragers using primarily the littoral-benthic zone and nearshore areas of the terminal (Ainley *et al.* 1981). Pelagic cormorants feed primarily on solitary prey in rocky reef substrates present at and around the existing terminal, and within smaller watercourses entering the inlet. This species, as an indicator, represents other larger piscivorous and typically sensitive marine birds that occur within the Marine RSA, such as western grebes, common loons and merganser species. The Marine Birds LSA has limited moderate to low value habitat for foraging and nesting due to existing structure, vessel activity and nearshore habitat disturbance; however, the Marine RSA does offer those opportunities. Therefore, the magnitude of effect from loss of nesting and foraging habitat in the Marine Bird LSA is low (Table 7.6.12-3, point 3[a]). The existing Westridge Marine Terminal pilings and berth that currently provide roosting habitat will be removed; however, the additional larger berths may provide enhanced nesting and roosting opportunities. The reversibility of habitat lost or disturbed is anticipated to be medium-term because altered habitats may recover or be enhanced to provide roosting and foraging during operations. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds LSA – effects are confined to the area of disturbance and construction associated with the terminal expansion and potentially includes marine protective structures within a portion of the Marine Birds LSA.
- Duration: short-term – the event will occur during the construction phase.
- Frequency: isolated – the event is confined to the construction phase of the Project.
- Reversibility: medium-term – habitat and habitat use is expected to recover in less than 10 years.
- Magnitude: low – effects will be detectable in the short-term but will begin to recover and potentially enhance post-construction.
- Probability: high – the Project is likely to alter habitat during construction.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and pelagic cormorants.

Sensory Disturbance Causing Stress, Behavioural Changes or Avoidance of Important Habitats

Increased in-air noise and activity at the terminal may result in the stress of individuals using preferred and/or important habitats near the terminal (the closest breeding colony is approximately 5 km from the terminal) or, alternatively, an alteration of normal movement patterns to avoid those preferred foreshore areas. The effects of underwater noise are difficult to assess without an established body of literature to inform thresholds for disturbance in birds. Substantial noise levels during pile-driving that may affect other marine animals, including fish and mammals, are expected to have some detectable behavioural effect on diving marine birds as well. Temporary sediment releases in marine waters surrounding the in-water construction sites could alter prey abundance or impede the bird’s ability to see and catch prey. Habituation to disturbance is known to occur in some marine bird species under some conditions. Constraints to obtaining life history requirements can adversely affect habitat effectiveness, individual fitness and population sustainability. With consideration for the context of existing volume of marine traffic and local industry, and the application of mitigation measures to prevent substantial noise disturbances to marine wildlife, the magnitude of the effect of disturbance is anticipated to be medium but long-term acting periodically over the life of terminal operations (Table 7.6.12-3, point 3[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects may extend into the RSA and beyond the ZOI specific to the visual and noise disturbance threshold (approximately 200 m) of the pelagic cormorant.
- Duration: long-term – the events causing sensory disturbance will be initiated during construction and extend throughout operations for the operational life of the Westridge Marine Terminal.

- Frequency: periodic – the events causing sensory disturbance (*i.e.,* noise and activity during construction and operations) will occur intermittently but repeatedly for the operational life of the Westridge Marine Terminal.
- Reversibility: short-term – although pelagic cormorants may habituate to a particular level of noise and human activity from temporary construction and long-term operations of the terminal, recovery from the effects from disturbances may be interrupted by subsequent marine activities.
- Magnitude: medium – effects will be detectable at the individual level but with mitigation may not be detectable at the population level with consideration for the context of abundant industry in the Marine RSA.
- Probability: high – the Project is likely to pose sensory disturbances to pelagic cormorant.
- Confidence: moderate – based on a good understanding by the assessment team of cause-effect relationships between Project activities and marine birds; however, data is lacking for the Project area.

Events of Accidental Injury or Mortality

Many species of marine birds are documented as sensitive to night lighting at marine terminals and on ships and which have resulted in rare events of harmful or fatal collisions with vessel or terminal infrastructure (Black 2005, ConocoPhillips 2011). In the context of the existing industrially developed environment of the Marine Birds LSA, these events would be accidental and rare for adults that have resided long-term in the area of Burrard Inlet. Considering the degree of lighting that currently exists both at the existing terminal and within the Vancouver Port area at night, it would be difficult to isolate the incremental effects of additional lighting that will be in place for the terminal expansion and vessels positioned at berths. Relatively long periods of sensory and in-air noise disturbances during pile-driving could potentially cause stress, or foraging habitat avoidance, in adult cormorants leading to nest abandonment or poor provisioning and, consequently, the mortality of eggs or hatchlings. However, the probability of this effect occurring is low considering the current location of established nest sites in Burrard Inlet and the presence of Environmental Inspectors during construction (Table 7.6.12-3, point 3[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine RSA – effects could extend to outside the direct area of disturbance, construction and operational facilities associated with the terminal expansion.
- Duration: long-term – the events causing potential injury or mortality to pelagic cormorants may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: accidental – the events causing potential injury or mortality to pelagic cormorants will occur rarely and accidentally over the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – each event of mortality would be restored within one generation of breeding and maturity of an individual.
- Magnitude: low – effects from rare events will be detectable at the individual level but with mitigation are unlikely to be detectable at the population level.
- Probability: low – mortality is possible but would be rare and unlikely to occur as a result of the Project.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and pelagic cormorants.

Combined Effects on Pelagic Cormorant

No pelagic cormorant nests are currently active within or near to the Westridge Marine Terminal and abundant shoreline habitat is available within the Marine RSA for foraging and roosting. A comprehensive environmental protection program (Westridge Marine Terminal EPP of Volume 6D) has been developed to reduce or eliminate potential harm to marine life during construction of the Westridge Marine Terminal, to include noise baffles, bubble curtains and timing windows (September 1 to January 31), and consider sensitive breeding (February 1 to August 31) and bird migration periods. The likelihood of noise levels capable of disturbances will decrease with distance from the source, for example during construction within the terminal Footprint or during in-water pile driving. Noise and activity are not expected be substantial to any extent beyond the Marine Bird LSA. To be exposed to sound levels capable of causing disturbance or harm, marine birds would need to be in close proximity to the site of the upland terminal and in-water pile-driving. At the time of this assessment, detailed engineering and parameters of noise and activity associated with pile-driving were not available. However, Trans Mountain will comply with mitigation measures set out in the Westridge Marine Terminal EPP (Volume 6D). A summary of the rationale for all of the significance criteria for combined effects on pelagic cormorant is provided below (Table 7.6.12-3, point 3[d]).

- Spatial Boundary: Marine Birds RSA – combined effects from construction and operations could potentially occur within all spatial scales of the assessment area.
- Duration: long-term – the events causing combined effects on pelagic cormorant may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing combined effects have the potential to occur intermittently but regularly for the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – potential combined effects of sensory disturbance, and habitat alteration or loss are expected to recover in less than 10 years.
- Magnitude: low – effects will be detectable at the individual level but are unlikely to be detectable at the population level.
- Probability: high – combined effects on the pelagic cormorant arising from the Project are likely to occur.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and pelagic cormorants.

Marine Bird Indicator – Barrow’s Goldeneye

The following subsections provide the evaluation of significance of potential residual effects on the Barrow’s goldeneye indicator.

Loss or Alteration of Foraging, Nesting and Roosting Habitat

Effects to Barrow’s goldeneyes are expected to be associated with the potential loss or alteration of nearshore marine foraging habitat in the Marine Birds LSA. Barrow’s goldeneyes are closely tied to intertidal zones where they forage for invertebrate species (Eadie *et al.* 2000). They winter mostly in marine habitats including bays, inlets, harbours and rocky shores. Feeding in shallow water, they primarily consume mussels but also clams, crustaceans, and fish eggs. As such, they are indicators representing other resident and migrating marine birds that are benthic and invertebrate foragers within the Marine RSA, such as, surf scoters, common goldeneye and some waterfowl species. The Marine Birds LSA has limited foraging habitat for this species in nearshore waters at the terminal; however, the larger Marine RSA does provide more suitable foraging and loafing opportunities. The existing terminal pilings provide minimal foraging opportunities for invertebrate prey; however, it is anticipated that this will be enhanced by the additional in-water structures of new berths. Invertebrate populations have been shown to establish on artificial marine structures within 2 to 3 years which can be utilized at times by foraging birds. Therefore, the magnitude of effects of habitat loss is anticipated to be low and have medium-term reversibility with consideration for the potential re-establishment of invertebrate communities at the new terminal site (Table 7.6.12-3, point 4[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds LSA – effects are confined to the area of disturbance and construction associated with the terminal expansion and potentially includes marine protective and berth infrastructures within a portion of the Marine Birds LSA.
- Duration: short-term – the event will occur during the construction phase.
- Frequency: isolated – the event is confined to the construction phase of the Project.
- Reversibility: medium-term – habitat and subsequent habitat use by Barrow's goldeneye is expected to recover in approximately 3 years years post-construction.
- Magnitude: low – effects will be detectable in the short-term but will begin to recover and potentially enhance post-construction.
- Probability: high – the Project is likely to alter habitat during construction.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and Barrow's goldeneyes, and data pertinent to the Marine RSA.

Sensory Disturbance Causing Stress, Behavioural Changes or Avoidance of Important Habitats

Increased in-air noise and activity at the Westridge Marine Terminal may result in the stress of individuals using preferred and/or seasonally important habitats near the terminal or, alternatively, an alteration of normal movement patterns to avoid those preferred but active intertidal zones. The effects of underwater noise are difficult to assess without an adequate body of literature to inform thresholds for disturbance in birds. Substantial noise levels during pile-driving that may affect other marine animals, including fish and mammals, are expected to have some detectable behavioural effect on diving marine birds as well. Temporary sediment releases in marine waters surrounding the in-water construction sites could alter prey abundance or impede the bird's ability to see and catch prey. Habituation is known to occur in some species in some conditions; however, this is difficult to assess. Goldeneyes use the inlet seasonally, flying inland to breed, and so have less time to become familiar with typical operational noises or other disturbance events. Constraints to obtaining life history requirements can adversely affect habitat effectiveness, individual fitness and population sustainability. With consideration for the context of the existing high-volume of marine traffic and local industry, and the application of mitigation measures to prevent substantial noise disturbances to marine wildlife, the magnitude of the effect of disturbance is anticipated to be medium but long-term acting periodically over the life of terminal operations (Table 7.6.12-3, point 4[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects may extend into the RSA and beyond the ZOI specific to the visual and noise disturbance threshold (approximately 100 m) of the Barrow's goldeneye.
- Duration: long-term – the events causing sensory disturbance will be initiated during construction and extend throughout operations for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing sensory disturbance (*i.e.,* noise and activity during construction and operations) will occur intermittently but repeatedly for the operational life of the Westridge Marine Terminal.
- Reversibility: short-term – although Barrow's goldeneye may habituate to a particular level of noise and human activity from temporary construction and long-term operations of the terminal, recovery from the effects of disturbance events may be interrupted by subsequent marine activities.
- Magnitude: medium – effects will be detectable at the individual level but with mitigation may not be detectable at the population level with consideration for the potential for familiarity with the context of abundant industrial development and activity in the Marine RSA.
- Probability: high – the Project is likely to cause sensory disturbances to Barrow's goldeneye.

- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and Barrow's goldeneyes.

Events of Accidental Injury or Mortality

Goldeneyes are associated with marine bird species that are documented as sensitive to night-lighting (Black 2005, Merkel and Johansen 2011) at marine terminals and on ships and which have resulted in rare events of harmful or fatal collisions with vessel or terminal infrastructure. In the context of the existing industrially developed environment of the Marine Birds LSA, these events would be accidental and rare (Table 7.6.12-3, point 4[c]) for adults that regularly use habitats to overwinter in the area of Burrard Inlet. Considering the degree of lighting that currently exists both at the existing terminal and within the Vancouver Port area at night, it would be difficult to isolate the incremental effects of additional lighting that will be in place for the terminal expansion and vessels positioned at berths. Relatively long periods of sensory disturbances during pile-driving or operations could potentially cause abandonment of important foraging opportunities during staging. Populations are considered stable in western Canada, although, there is potential for mortality of some young individuals who may not survive overwintering or predator disturbance events. Other local watercourses associated with the Burrard Inlet are rich in seasonal foraging habitats and exposure to potential harmful events at the terminal is anticipated to be of low probability for the operational life of the Westridge Marine Terminal (Table 7.6.12-3, point 4[c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects could extend to outside the direct area of disturbance, construction and operational facilities associated with the terminal expansion.
- Duration: long-term – the events causing potential injury or mortality to Barrow's goldeneyes may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: accidental – the events causing potential injury or mortality to Barrow's goldeneyes will occur rarely over the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – each event of mortality would be restored within one generation of breeding and maturity of an individual.
- Magnitude: low – effects will be detectable at the individual level but with mitigation are unlikely detectable at the population level.
- Probability: low – mortality is possible but will be rare and unlikely to occur as a result of the Project.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and Barrow's goldeneyes.

Combined Effects on Barrow's Goldeneye

Abundant nearshore and rocky shoreline areas are available within the Marine RSA for foraging and resting. A comprehensive environmental protection program (Westridge Marine Terminal EPP of Volume 6D) has been developed to reduce or eliminate potential harm to marine life during construction of the Westridge Marine Terminal, to include noise baffles, bubble curtains and timing windows with consideration for sensitive spring and fall migration periods. The likelihood of noise levels capable of disturbances will decrease with distance from the source, for example during construction within the terminal footprint or during in-water pile driving. Noise and activity are not expected be substantial to any extent beyond the Marine Bird LSA. To be exposed to sound levels capable of causing disturbance or harm, marine birds would need to be in close proximity to the site of the upland terminal and in-water pile-driving. At the time of this assessment, detailed engineering and parameters of noise and activity associated with pile-driving were not available. However, Trans Mountain will comply with mitigation measures set out in the Westridge Marine Terminal EPP (Volume 6D). A summary of the rationale for all of the significance criteria for combined effects on Barrow's goldeneye is provided below (Table 7.6.12-3, point 4[d]).

- Spatial Boundary: Marine Birds RSA – combined effects from construction and operations could potentially occur within all spatial scales of the assessment area.
- Duration: long-term – the events causing combined effects on pelagic cormorant may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing combined effects have the potential to occur intermittently but regularly for the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – potential combined effects of sensory disturbance, and habitat alteration or loss are expected to recover in less than 10 years.
- Magnitude: low – combined effects will be detectable at the individual level but are unlikely to be detectable at the population level.
- Probability: high – combined effects on the Barrow's goldeneye arising from the Project are likely to occur.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and Barrow's goldeneyes.

Marine Bird Indicator – Glaucous-winged Gull

The following subsections provide the evaluation of significance of potential residual effects on the glaucous-winged gull indicator.

Loss or Alteration of Foraging, Nesting and Roosting Habitat

Effects to glaucous-winged gulls are expected to be associated with the potential loss or alteration of nesting, roosting and foraging habitat in the Marine Birds LSA. Gulls fish and scavenge opportunistically and are abundant generalists in the natural and anthropogenic environments of the Maine RSA. They are indicators of a wide range of other marine birds that forage and nest within the Marine RSA due their versatile habitat use and strong-association with human-influenced environments, and as in other species, their sensitivity during the breeding cycle, particularly during egg-laying and incubation. As such they also overlap with representativeness provided by some other marine bird indicators, for example, locally breeding cormorants and herons, scavenging raptors and fish-eating seabird species. There are several breeding colonies within the Marine RSA, including one colony site within 1 km of the terminal on the south shore of Port Moody Arm, and abundant roosting areas throughout the Marine Birds LSA and Marine RSA (Suraci and Dill 2011). The population is healthy with many natural and anthropogenically altered sites available for foraging, roosting and breeding. The existing Westridge Marine Terminal pilings and berth that currently provide roosting habitat will be removed; however, the additional larger berths may provide enhanced nesting and roosting opportunities. Therefore, the magnitude habitat loss is anticipated to be low with a medium-term reversibility with consideration for the potential re-establishment of invertebrate communities at the new terminal site (Table 7.6.12-3, point 5[a]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds LSA – effects are confined to the area of disturbance and construction associated with the Terminal expansion and potentially includes marine protective structures within a portion of the Marine Birds LSA.
- Duration: short-term – the event will occur during the construction phase.
- Frequency: isolated – the event is confined to the construction phase of the Project.
- Reversibility: medium-term – habitat and habitat use is expected to recover in less than 10 years.
- Magnitude: low – effects will be detectable in the short-term but will begin to recover and potentially be enhanced post-construction by new wharf infrastructure.

- Probability: high – the Project is likely to alter habitat during construction.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and marine birds and data pertinent to the Marine RSA.

Sensory Disturbance Causing Stress, Behavioural Changes or Avoidance of Important Habitats

Increased in-air noise and activity at the Westridge Marine Terminal may result in the disturbance of some individuals using preferred habitats or, an avoidance of preferred foreshore areas. Substantial noise levels during dredging and pile-driving are expected to have some detectable effect on individual gulls; however, some proportion of the population is assumed to be familiar with the noise and activity at abundant local industrial sites. Temporary sediment releases in marine waters surrounding the in-water construction sites could alter prey abundance or prey capture. The habituation of gulls to anthropogenic disturbances and urban environments is known to occur; however, constraints from obtaining life history requirements can result in adverse effects to habitat effectiveness, and individual fitness. With consideration for the context of existing marine traffic and local industry, the association of gulls with human developments, and the application of mitigation measures to prevent disturbance to sensitive nesting colonies, the magnitude of the effect of disturbance is anticipated to be low but long-term acting occasionally over the life of terminal operations (Table 7.6.12-3, point 5[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine RSA – effects will extend beyond the Footprint into a ZOI specific to the visual and noise disturbance threshold of the glaucous-winged gull.
- Duration: long-term – effects will be initiated during construction and extend throughout operations for the operational life of the Westridge Marine Terminal.
- Frequency: occasional – effect is expected to occur intermittently and sporadically for the operational life of the Westridge Marine Terminal with consideration for the known tendency of glaucous-winged gulls for habituation and adaptiveness to urban environments.
- Reversibility: short-term – although glaucous-winged gulls commonly habituate to a particular level of noise and human activity, recovery from substantial persistent disturbances during temporary construction and long-term operations of the terminal may be interrupted by subsequent marine activities.
- Magnitude: low – effects may be detectable at the individual level but are not likely to be detectable at the population level with consideration for likely habituation to the context of abundant industry in the Marine RSA.
- Probability: high – the Project is likely to cause sensory disturbances to glaucous-winged gulls.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and glaucous-winged gulls.

Events of Accidental Injury or Mortality

The risk of gull collisions with terminal infrastructure is very unlikely given the large local population, their affinity for human-influenced sites and marine structures, and their tendency to habituate to urban and industrial settings; however, this could potentially occur during events of high wind and inclement weather. In the context of the existing industrially developed Marine Bird LSA, these events would be considered accidental and rare for adults that regularly use the area of Burrard Inlet. Breeding colonies are highly sensitive, and relatively long periods of sensory disturbances (*i.e.,* during pile-driving could potentially cause adult gulls to abandon nests at the nearby colony during the breeding season). This would cause the subsequent mortality of exposed eggs or hatchlings. However, mitigation measures will be established to avoid such an event and reduce disturbance during this sensitive period. In addition an Environmental Inspector will be made aware of the location, timing and sensitivity of the breeding site prior to onset of construction activities. A summary of the rationale for all of the significance criteria is provided below (Table 7.6.12-3, point 5[c]).

- Spatial Boundary: Marine RSA – effects could extend to outside the direct area of disturbance, construction and operational facilities associated with the terminal expansion.
- Duration: long-term – the events causing potential injury or mortality to glaucous-winged gulls may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: accidental – the events causing potential injury or mortality to glaucous-winged gulls will occur rarely and accidentally over the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – each event of mortality would be restored within one generation of breeding and maturity of an individual.
- Magnitude: low – effects from rare events will be detectable at the individual level but with mitigation are unlikely to be detectable at the population level.
- Probability: low – mortality is possible but will be rare and unlikely to occur as a result of the Project.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and glaucous-winged gulls.

Combined Effects on Glaucous-winged Gulls

One breeding colony is active near the Westridge Marine Terminal. The sensitive breeding period is from early May (egg-laying) extending often into late August (fledging). A comprehensive environmental protection program (Westridge Marine Terminal EPP of Volume 6D) has been developed to reduce or eliminate potential harm to marine life during construction of the Westridge Marine Terminal, to include noise baffles, bubble curtains and timing windows that consider sensitive breeding periods (February 1 to August 31 during each of the projected 2 years of construction). The likelihood of noise levels capable of disturbances will decrease with distance from the source, for example during construction within the terminal Footprint or during in-water pile driving. Noise and activity are not expected be substantial to any extent beyond the Marine Birds LSA. To be exposed to sound levels capable of causing disturbance or harm, marine birds would need to be in close proximity to the site of the upland terminal and in-water pile-driving. At the time of this assessment, detailed engineering and parameters of noise and activity associated with pile-driving were not available. However, Trans Mountain will comply with mitigation measures set out in the Westridge Marine Terminal EPP (Volume 6D). A summary of the rationale for all of the significance criteria for combined effects on glaucous-winged gulls is provided below (Table 7.6.12-3, point 5[d]).

- Spatial Boundary: Marine RSA – combined effects from construction and operations could potentially occur within all spatial scales of the assessment area.
- Duration: long-term – the events causing combined effects on glaucous-winged gull may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: occasional – the events causing combined effects are expected to occur intermittently and sporadically for the operational life of the Westridge Marine Terminal with consideration for glaucous-winged gulls to habituate and adapt in urban environments.
- Reversibility: medium-term – potential combined effects of sensory disturbance, and habitat alteration or loss are expected to recover in less than 10 years.
- Magnitude: low – combined effects will be detectable at the individual level but are unlikely to be detectable at the population level.
- Probability: high – combined effects on the glaucous-winged gull arising from the Project are likely to occur.

- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and glaucous-winged gulls, and data relevant to the Marine RSA.

Marine Bird Indicator – Spotted Sandpiper

The following subsections provide the evaluation of significance of potential residual effects on the spotted sandpiper indicator.

Loss or Alteration of Foraging, Nesting and Roosting Habitat

Effects to the spotted sandpiper are expected to be associated with the potential loss or alteration of nesting and foraging habitat at the foreshore of the Marine Birds LSA. There will be 2,685 m^2 (0.27 ha) of marine riparian habitat lost due to terminal construction, a small portion of which is suitable sandpiper spotted sandpiper shoreline foraging and nesting habitat. Spotted sandpipers use a variety of aquatic habitats; nesting at shores, near streams and lakes, and require herbaceous vegetation at these sites as ground cover for their nests. During migration periods and in winter, they can be found at mudflats, beaches, breakwaters, and sewage ponds foraging exclusively on invertebrates. Spotted sandpipers are indicators of a diversity of small and large migratory sandpiper species, and resident passerines (such as song sparrows), which use the intertidal and foreshore areas seasonally to forage on insects and other invertebrates, and to nest in shoreline vegetation, nest boxes (such as purple martin) and debris. The Marine Birds LSA has limited foreshore value for foraging and nesting habitat for this species; however, the Marine RSA does contain abundant suitable habitat, especially at Maplewood Conservation Area. Therefore, the magnitude of effect from loss of nesting and foraging habitat in the Marine Bird LSA is low (Table 7.6.12-3, point 6[a]). The reversibility of habitat lost or disturbed is anticipated to be medium-term because altered habitats may recover during operations. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – effects are confined to the area of disturbance and construction associated with the terminal expansion.
- Duration: short-term – the event causing habitat alteration or loss will occur during the construction phase.
- Frequency: isolated – the event causing habitat alteration or loss is confined to the construction phase of the Project.
- Reversibility: medium-term – habitat and habitat use is expected to recover in less than 10 years.
- Magnitude: low – effects will be detectable in the short-term but will begin to recover post-construction.
- Probability: high – the Project is likely to alter habitat during construction.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and spotted sandpiper, and data relevant to the Project area.

Sensory Disturbance Causing Stress, Behavioural Changes or Avoidance of Important Habitats

Increased in-air noise and activity at the Westridge Marine Terminal may result in the stress of groups or individuals using preferred and/or important habitats or, alternatively, an alteration of normal movement patterns through avoidance of those preferred foreshore and shoreline foraging areas. Substantial noise levels during dredging and pile-driving are expected to have some detectable effect on sandpipers. Like other sandpipers, they tend to flush easily during human disturbance events. Levels of habituation are not well known in this species; however, sandpipers are known to be reactive in a relatively short threshold distance during human disturbances. Constraints from obtaining life history requirements can result in adverse effects to habitat effectiveness, changes in critical energy budgets, reduced individual fitness, and the potential for minimal effects to local population sustainability. With consideration for the context of existing local industry, and the application of mitigation measures to prevent substantial noise disturbances to marine wildlife, the magnitude of the effect of disturbance is anticipated to be medium for the long-term acting periodically over the life of terminal operations (Table 7.6.12-3, point 6[b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine RSA – effects will extend beyond the Footprint into a ZOI specific to the visual and noise disturbance threshold (approximately 50 m) of the sandpiper.
- Duration: long-term – the events causing sensory disturbance will be initiated during construction and extend throughout operations for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing sensory disturbance (*i.e.,* noise and activity during construction and operations) will occur intermittently but repeatedly for the operational life of the Westridge Marine Terminal.
- Reversibility: short-term – although spotted sandpipers may habituate to a particular level of noise and human activity from temporary construction and long-term operations of the terminal, recovery from the effects from disturbances may be interrupted by subsequent marine activity.
- Magnitude: medium – effects will be detectable at the individual level but with mitigation may not be detectable at the population level with consideration for the potential for some level of habituation to the context of abundant industry in the Marine RSA.
- Probability: high – the Project is likely to create sensory disturbances to spotted sandpiper.
- Confidence: moderate – based on a good understanding by the assessment team of cause-effect relationships between Project activities and spotted sandpiper; however, data is lacking for the Project area.

Events of Accidental Injury or Mortality

Spotted sandpipers are among marine bird species that are documented as sensitive to night lighting at marine terminals and on ships and which have resulted in rare events of harmful or fatal collisions with vessel or terminal infrastructure. Sandpipers could potentially collide in flight, or be injured, by vessel or terminal infrastructure during migration or if they are flying through bad weather; however, these events would be accidental and rare (Table 7.6.12-3, point 6[c]). Considering the degree of lighting that currently exists both at the existing terminal and within the Vancouver Port area at night, it would be difficult to isolate the incremental effects of additional lighting that will be in place for the Terminal expansion and vessels positioned at berths. A small amount of breeding and foraging habitat is available near the terminal expansion site. Relatively long periods of sensory disturbances during pile-driving could potentially cause adult sandpipers to abandon nests located near the terminal, and not previously detected by Environmental Inspectors. This could result in subsequent mortality of exposed eggs or hatchlings. However, the probability of this effect occurring is low considering the minimal nesting habitat available now and in future, and the current level of noise and activity that currently takes place, which may deter sandpipers from using these lower suitability habitats near the terminal. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Marine Birds RSA – effects could extend to outside the direct area of disturbance, construction and operational facilities associated with the Terminal expansion.
- Duration: long-term – the effect of bird injury or mortality from collisions with terminal infrastructure could occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal. The effect of bird mortality from nest abandonment would be limited to the construction phase.
- Frequency: accidental – effects have the potential to occur rarely over the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – each event of mortality would be restored within one generation of breeding and maturity of an individual.

- Magnitude: low – effects from rare events will be detectable at the individual level but if mitigated are unlikely to be detectable at the population level.
- Probability: low – mortality is possible but will be rare and unlikely to occur as a result of the Project.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and marine birds.

Combined Effects on Spotted Sandpiper

No spotted sandpiper nests have been documented at the shoreline or within the terminal Footprint. Abundant shoreline is available within the Marine RSA for foraging and perching. A comprehensive environmental protection program (Westridge Marine Terminal EPP of Volume 6D) has been developed to reduce or eliminate potential harm to marine life during construction of the Westridge Marine Terminal, to include noise baffles, bubble curtains and timing windows that consider sensitive breeding (February 1 to August 31) and migration periods. The likelihood of noise levels capable of disturbances will decrease with distance from the source, for example during construction within the terminal footprint or during in-water pile driving. Noise and activity are not expected be substantial to any extent beyond the Marine Birds LSA. To be exposed to sound levels capable of causing disturbance or harm, marine birds would need to be in close proximity to the site of the upland terminal and in-water pile-driving. At the time of this assessment, detailed engineering and parameters of noise and activity associated with pile-driving were not available. However, Trans Mountain will comply with the mitigation measures set out in the Westridge Marine Terminal EPP (Volume 6D). A summary of the rationale for all of the significance criteria for combined effects on spotted sandpiper is provided below (Table 7.6.12-3, point 6[d]).

- Spatial Boundary: Marine Birds RSA – combined effects from construction and operations could potentially occur within all spatial scales of the assessment area.
- Duration: long-term – the events causing combined effects on spotted sandpiper may occur during construction and throughout the operations phase for the operational life of the Westridge Marine Terminal.
- Frequency: periodic – the events causing combined effects have the potential to occur intermittently but repeatedly for the operational life of the Westridge Marine Terminal.
- Reversibility: medium-term – potential combined effects of sensory disturbance, and habitat alteration or loss are expected to recover in less than 10 years.
- Magnitude: low – effects will be detectable at the individual level but are unlikely to be detectable at the population level.
- Probability: high – the combined effects on the spotted sandpiper arising from the Project are likely to occur.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between the Project activities and spotted sandpiper.

7.6.12.7 Summary

As identified in Table 7.6.12-3, there are no situations where there is a high probability of the occurrence of a permanent long-term residual effect on marine bird indicators of high magnitude from Project-related activities that cannot be technically mitigated. Consequently, it is concluded that the residual environmental effects of construction and operation activities at the Westridge Marine Terminal on marine bird indicators will be not significant.

7.6.13 Species at Risk

The construction and operations of Project activities at the Westridge Marine Terminal may affect wildlife, marine fish, marine mammals and marine bird species at risk. Section 7.2.11 provides a discussion of the wildlife species used as indicators for species at risk. Although not all species at risk are discussed explicitly under each indicator, potential Project effects were assessed in consideration of all species at risk. The indicators used to represent wildlife and wildlife habitat, marine fish and fish habitat, marine mammals and marine birds were carefully selected to ensure that the full range of potential Project effects on species at risk was addressed and mitigation measures to reduce these effects will apply to all species at risk, not just the indicators. Section 7.2.10 Wildlife and Wildlife Habitat, Section 7.6.9 Marine Fish and Fish Habitat, Section 7.6.11 Marine Mammals and Section 7.6.12 Marine Birds provide the significance rationale for applicable indicator species. No significant adverse effects on species at risk have been identified as a result of the pipeline and facilities component of the Project.

7.7 Effects Assessment – Pipeline Reactivation Activities

Using the assessment methodology described in Section 7.1, the following subsection evaluates the potential environmental effects associated with the reactivation of the existing pipeline segments from Hinton to Hargreaves and Darfield to Black Pines, as well as associated activities such as the installation of automated valves.

Environmental elements potentially interacting with the pipeline reactivation include:

- physical elements such as soil and soil productivity, water quality and quantity, air emissions, GHG emissions and acoustic environment; and
- biological elements such as fish and fish habitat, vegetation, wildlife and wildlife habitat, and species at risk.

Environmental elements which are not considered to interact with the reactivation of the Hinton to Hargreaves or the Darfield to Black Pines segments are summarized in Table 7.7-1. Spatial boundaries for the assessment of the reactivation of the existing pipeline segments are the same as in the applicable subsection of Section 7.2 unless otherwise noted.

TABLE 7.7-1

ELEMENTS NOT INTERACTING WITH PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES

Element	Justification
Physical and Meteorological Environment	There are no potential effects associated with physical environment indicators anticipated to result from pipeline reactivation activities.
Wetland Loss or Alteration	Wetlands are not expected to be disturbed along any of the reactivated pipeline segments.
Wildlife and Wildlife Habitat	The pipeline reactivation activities are not expected to have a measurable impact on wildlife and wildlife habitat. Habitat disturbance will be limited to a similar level of sensory disturbance as would occur during pipeline maintenance activities. Any potential effects will be short-term and of low magnitude.

7.7.1 Soil and Soil Productivity

Sections 7.2.2.1, 7.2.2.2 and 7.2.2.3 provides the assessment indicators, measurement endpoints, spatial boundaries and ecological assessment for the assessment of potential effects of Project activities at pump station facilities on soil and soil productivity.

7.7.1.1 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

Potential effects associated with pipeline reactivation activities on soil and soil productivity indicators are listed in Table 7.7.1-1. These interactions were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.7.1-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.2.4. Pipeline reactivation activities in Jasper National Park along the Hinton to Hargreaves Segment will follow the Jasper National Park Operations and Maintenance Environmental Protection Plan (TERA 2009).

TABLE 7.7.1-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON SOIL AND SOIL PRODUCTIVITY

Potential Effect	Pipeline Reactivation Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Soil Indicator – Soil Productivity				
1.1 Decreased topsoil/root zone material productivity during topsoil/root zone material salvaging	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Mixing of topsoil/root zone material and subsoil.
1.2 Decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land	All	LSA	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• No residual effect identified.
1.3 Decreased soil productivity from soil diseases (*i.e.,* clubroot disease and potato cyst nematode)	All	LSA	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Clubroot disease introduction and spread. Potato cyst nematode introduction and spread.
2. Soil Indicator – Soil Degradation				
2.1 Degradation of soil structure due to compaction and rutting	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Degradation of soil structure and impairment of rooting zone due to compaction and rutting.
2.2 Loss of topsoil/root zone material through wind and water erosion.	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.
2.3 Degradation of soil structure due to pulverization of soil and sod	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.
2.4 Erosion of soil as a result of release of hydrostatic test water on land	All	LSA	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• No residual effect identified.
3. Soil Indicator – Soil Contamination				
3.1 Disturbance of previously contaminated soil	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• No residual effect identified.
3.2 Contamination of soil as a result of release of hydrostatic test water on land	All	LSA	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• No residual effect identified.
3.3 Soil contamination due to spot spills during construction	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.2-2 Soil and Soil Productivity.	• No residual effect identified.

Notes: 1 LSA = Soil LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.7.1.2 Potential Residual Effects

The potential residual environmental effects of pipeline reactivation and associated activities on soil and soil productivity indicators (Table 7.7.1-1) are:

- mixing of topsoil/root zone material and subsoil;
- clubroot disease and potato cyst nematode introduction and spread;
- degradation of soil structure and impairment of rooting zone due to compaction and rutting;
- surface erosion of topsoil/root zone material can be expected until a vegetative cover is established; and

- pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.

Some of the potential effects on element indicators associated with pipeline reactivation and associated activities are predicted to be eliminated through the implementation of mitigation measures (Table 7.7.1-1). The potential effects determined not to have a residual effect are:

- decreased soil productivity from flooding of soil as a result of release of hydrostatic test water on land;
- erosion of soil as a result of release of hydrostatic test water on land;
- disturbance of previously contaminated soil;
- contamination of soil as a result of hydrostatic test water on land; and
- soil contamination due to spot spills during construction.

7.7.1.3 Significance Evaluation of Potential Residual Effects

Table 7.7.1-2 provides a summary of the significance evaluation of the potential residual environmental effects on soil and soil productivity indicators associated with pipeline reactivation and associated activities.

TABLE 7.7.1-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON SOIL AND SOIL PRODUCTIVITY

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Soil Indicator – Soil Productivity									
1(a)	Mixing of topsoil/root zone material and subsoil.	Negative	Footprint	Short-term	Periodic	Medium-term	Low	High	High	Not significant
1(b)	Clubroot disease and potato cyst nematode introduction and spread.	Negative	LSA	Short-term	Accidental	Long-term	High	Low	Moderate	Not significant
2.	Soil Indicator – Soil Degradation									
2(a)	Degradation of soil structure and impairment of rooting zone due to compaction and rutting.	Negative	Footprint	Short-term	Periodic	Short to medium-term	Low	High	High	Not significant
2(b)	Surface erosion of topsoil/root zone material can be expected until a vegetative cover is established.	Negative	Footprint	Short-term	Periodic	Medium-term	Low	High	High	Not significant
2(c)	Pulverization resulting in fugitive dust and loss of soil structure can be expected during dry conditions.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	Low to high	High	Not significant
2(d)	Combined effects on the soil degradation indicator (2[a] to 2[c]).	Negative	Footprint	Short-term	Periodic	Short to medium-term	Low	High	High	Not significant

Notes: 1 LSA = Soil LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the soil productivity indicator and soil degradation indicator was determined to be the same for pipeline reactivation and associated activities as for pipeline construction and operations (Table 7.7.1-2, points 1[a], 1[b] and 2[a] to 2[d]). The exception is the frequency of the event (*i.e.*, hydrostatic testing) which is limited to a specific phase of the assessment.

Table 7.2.2-3 and the accompanying discussion in Section 7.2.2.6 provide an evaluation of potential residual effects of reactivation activities and their significance on the applicable soil and soil productivity indicator.

7.7.1.4 Summary

As identified in Table 7.7.1-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on soil and soil productivity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with pipeline reactivation and associated activities on soil and soil productivity will be not significant.

7.7.2 Water Quality and Quantity

Sections 7.2.3.1 and 7.2.3.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of pipeline reactivation and associated activities on water quality and quantity.

7.7.2.1 Water Quality and Quantity Context

The Hinton to Hargreaves reactivated pipeline segment is located within the Athabasca River Basin in Alberta and the Fraser River Basin in BC. The Darfield to Black Pines reactivated pipeline segment is located within the Lower North Thompson River Watershed of the Fraser River Basin.

Reactivation of the Hinton to Hargreaves and Darfield to Black Pines pipeline segments will require hydrostatic testing. Source test water for the Hinton to Hargreaves Segment is likely to be withdrawn from the Athabasca, Snaring, Miette and Fraser rivers, as well as Moose Lake. Source test water for the Darfield to Black Pines Segment is likely to be drawn from the North Thompson River.

Section 5.13 provides additional setting information related to water quality and quantity along the reactivated pipeline segments.

7.7.2.2 Potential Effects and Mitigation Measures

Identified Potential effects

Potential effects associated with pipeline reactivation activities on the water quality and quantity indicators listed in Table 7.7.2-1 were based on the results of the literature review, desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.7.2-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.3.4. Pipeline reactivation activities in Jasper National Park along the Hinton to Hargreaves Segment will follow the Jasper National Park Operations and Maintenance Environmental Protection Plan (TERA 2009).

TABLE 7.7.2-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON WATER QUALITY AND QUANTITY

Potential Effect	Pipeline Reactivation Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Water Quality and Quantity Indicator – Surface Water Quality				
1.1 Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water	Hinton to Hargreaves Athabasca River Snaring River Miette River Fraser River Moose Lake Darfield to Black Pines North Thompson River	LSA	• Assess reactivated segments using in-line inspection tools. Specific locations along the pipeline will be physically inspected and repaired, if required, as determined necessary to ensure structural integrity. Following inspection, in-line cleaning tools will be used to scrub the pipe walls and remove residual hydrocarbon products and debris. • See recommended mitigation measures outlined in Table 7.2.3-2 Water Quality and Quantity.	• Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water.
1.2 Reduction of surface water quality from small spill during reactivation activities	Hinton to Hargreaves Darfield to Black Pines	LSA	• See recommended mitigation measures outlined in Table 7.2.3-2 Water Quality and Quantity.	• Contamination of surface water due to a small spill during construction at valve sites.
2. Water Quality and Quantity Indicator – Surface Water Quantity				
2.1 Localized alteration of natural surface drainage patterns during reactivation activities	Hinton to Hargreaves Darfield to Black Pines	LSA	• See recommended mitigation measures outlined in Table 7.2.3-2 Water Quality and Quantity.	• Localized alteration of natural surface drainage patterns at valve sites.
2.2 Alteration of streamflow volumes as a result of withdrawal and release of hydrostatic test water	Hinton to Hargreaves Athabasca River Snaring River Miette River Fraser River Moose Lake Darfield to Black Pines North Thompson River	LSA	• See recommended mitigation measures outlined in Table 7.2.3-2 Water Quality and Quantity.	• No residual effect identified.

Notes: 1 LSA = Water Quality and Quantity LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.7.2.3 Potential Residual Effects

The potential residual environmental effects of pipeline reactivation and associated activities on water quality and quantity indicators (Table 7.7.2-1) are:

- alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water;
- contamination of surface water due to a small spill during construction at valve sites; and
- localized alteration of natural surface drainage patterns at valve sites.

Alteration of streamflow volumes is concluded to not be a residual effect associated with reactivation activities following implementation of mitigation measures (Table 7.7.2-1).

7.7.2.4 Significance Evaluation of Potential Residual Effects

Table 7.7.2-2 provides a summary of the significance evaluation of the potential residual environmental effects of the reactivation activities on water quality and quantity.

TABLE 7.7.2-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON WATER QUALITY AND QUANTITY

	Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
				Duration	Frequency	Reversibility				
1.	Water Quality and Quantity Indicator – Surface Water Quality									
1(a)	Alteration or contamination of aquatic environment as a result of withdrawal and release of hydrostatic test water.	Negative	LSA	Short-term	Isolated	Immediate to short-term	Low	Low	High	Not significant
1(b)	Contamination of surface water due to a small spill during construction at valve sites.	Negative	LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
2.	Water Quality and Quantity Indicator – Surface Water Quantity									
2(a)	Localized alteration of natural surface drainage patterns at valve sites.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low to medium	High	High	Not significant

Notes: 1 LSA = Water Quality and Quantity LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects for the surface water quality and surface water quantity indicators was determined to be the same as for the construction and operations of the pipeline. Table 7.2.3-3 and the accompanying discussion in Section 7.2.3.6 provide an evaluation of these potential residual effects of reactivation activities and their significance on the applicable water quality and quantity indicator.

7.7.2.5 Summary

As identified in Table 7.7.2-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the water quality and quantity indicators of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects associated with pipeline reactivation and associated activities on water quality and quantity will be not significant.

7.7.3 Air Emissions

Sections 7.2.4.1 and 7.2.4.2 provide the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of pipeline reactivation and associated activities on air emissions.

Air emissions associated with pipeline reactivation activities (*e.g.*, hydrostatic testing, use of equipment) is anticipated to be minor in comparison to the construction of other Project components and pipeline operations of the reactivated segments are expected to be negligible.

7.7.3.1 Potential Effects and Mitigation Measures

Identified Potential Effects

The potential effects on the air emissions indicators associated with pipeline reactivation activities and listed in Table 7.7.4-1 were based on the results of the desktop analysis and the professional experience of the assessment team.

A summary of the mitigation measures provided in Table 7.7.4-1 was principally developed in accordance with Trans Mountain standards and accepted pipeline construction methods for construction-related activities.

TABLE 7.7.4-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON AIR EMISSIONS

Potential Effect	Pipeline Reactivated Segments	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds				
1.1 Project contribution to emissions	All	RSA	• See recommended mitigation measures outlined in Table 7.2.4-3, Air Emissions.	• Increase in air emissions during pipeline reactivation activities.

Notes: 1 RSA = Air Quality RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.7.3.2 Potential Residual Effects

The potential residual environmental effects on the air emissions indicator associated with pipeline reactivation and associated activities (Table 7.7.4-1) is an increase in air emissions during pipeline reactivation activities.

7.7.3.3 Significance Evaluation of Potential Residual Effects

Table 7.7.4-2 provides a summary of the significance evaluation of the potential residual environmental effects of pipeline reactivation and associated activities on air emissions.

TABLE 7.7.4-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON AIR EMISSIONS

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Air Emissions Indicator – Primary Emissions of Criteria Air Contaminants and Volatile Organic Compounds									
1(a) Increase in air emissions during pipeline reactivation activities.	Negative	RSA	Short-term	Isolated	Short-term	Low	High	Moderate	Not significant

Notes: 1 RSA = Air Quality RSA.
2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the primary emissions of CACs and VOCs indicator (Table 7.7.4-2, point 1[a]) was determined to be the same for the pipeline reactivation activities as for pipeline construction and operations. The exceptions are the frequency which is limited to the construction phase (isolated) and the magnitude which is low given the extent of activities associated with reactivation. Table 7.2.4-4 and the accompanying discussion in Section 7.2.4.6 provide an evaluation of the potential residual effects of pipeline reactivation and associated activities and their significance on the primary emissions of CACs and VOCs indicator.

7.7.3.4 Summary

As identified in Table 7.7.4-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the air emissions indicator of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the residual environmental effects of pipeline reactivation and associated activities on air emissions will be not significant.

7.7.4 Greenhouse Gas Emissions

As discussed in Section 7.2.5.3, during operation of the reactivated pipeline segments, the main sources of GHG emissions will be regular transportation and equipment use during maintenance activities. Pipeline reactivation related GHG emissions are summarized in Table 7.2.5-6.

The assessment of effects on GHG emissions has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks, Westridge Marine Terminal and pipeline reactivation), since GHG emissions associated with the construction and operation of each Project component are aggregated for the Project as a whole and then compared to provincial and federal GHG inventory totals.

The assessment of effects on GHG emissions for the Project as a whole is presented in Section 7.2.5. Table 7.2.5-8 and accompanying discussion in Section 7.2.5.3 provide an evaluation of potential residual effects of pipeline reactivation and associated activities on GHG indicators.

7.7.5 Acoustic Environment

Sections 7.2.6.1, 7.2.6.2 and 7.4.6 provide the assessment indicators, measurement endpoints, spatial boundaries and acoustic environment context for the assessment of potential effects of pipeline reactivation and associated activities on the acoustic environment.

7.7.5.1 Potential Effects and Mitigation Measures

Potential effects associated with pipeline reactivation activities on the acoustic environment indicators listed in Table 7.7.5-1 were based on the results of the desktop analysis and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.7.5-1 was principally developed in accordance with Trans Mountain standards and industry and provincial regulatory guidelines as described in Section 7.2.6.4.

TABLE 7.7.5-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON THE ACOUSTIC ENVIRONMENT

Potential Effect	Pipeline Reactivated Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Acoustic Environment Indicator – Sound Levels				
1.1 Changes in sound levels during reactivation activities	All	LSA	• See recommended mitigation measures in Table 7.2.6-2 Acoustic Environment.	• Increase in sound levels during pipeline reactivation activities.
1.2 Changes in sound levels during operation	All	LSA	• See recommended mitigation measures in Table 7.2.6-2 Acoustic Environment.	• Periodic noise events due to maintenance and inspections.

Notes: 1 LSA = Acoustic Environment LSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.7.5.2 Residual Effects

The potential residual environmental effects of pipeline reactivation and associated activities on acoustic environment indicators (Table 7.7.5-1) are:

- increase in sound levels during pipeline reactivation activities; and
- noise events due to maintenance and inspections.

7.7.5.3 Significance of Residual Effects

Table 7.7.5-2 provides a summary of the significance evaluation of the potential residual environmental effects of the reactivation activities on the acoustic environment.

TABLE 7.7.5-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON THE ACOUSTIC ENVIRONMENT

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Acoustic Environment – Sound Levels									
1(a) Increase in sound levels during pipeline reactivation activities.	Negative	LSA	Short-term	Isolated	Short-term	Low to medium	High	Moderate	Not significant
1(b) Periodic noise events due to maintenance and inspections.	Negative	LSA	Short-term	Periodic	Immediate to short-term	Negligible to medium	High	Moderate	Not significant
1(c) Combined effects on the sound levels indicator (1[a]) and 1[b]).	Negative	LSA	Short-term	Isolated	Short-term	Low to medium	High	Moderate	Not significant

Notes: 1 LSA = Acoustic Environment LSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects on the sound levels indicator was determined to be the same for pipeline reactivation and associated activities as for pipeline construction and operations (Table 7.7.5-2, points 1[a] to 1[c]). Table 7.2.6-3 and the accompanying discussion in Section 7.2.6.6 provide an evaluation of potential residual effects of reactivation activities and their significance on the applicable sound levels indicator.

7.7.5.4 Summary

As identified in Table 7.7.5-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on acoustic environment indicators of high magnitude. Consequently, is it concluded that the residual environmental effects associated with pipeline reactivation and associated activities on the acoustic environment will be not significant.

7.7.6 Fish and Fish Habitat

Reactivation of the Hinton to Hargreaves and Darfield to Black Pines pipeline segments will require hydrostatic testing. Source test water for the Hinton to Hargreaves Segment is likely to be drawn from the Athabasca, Snaring, Miette and Fraser rivers, as well as Moose Lake. Source test water for the Darfield to Black Pines Segment is likely to be drawn from the North Thompson River.

The Hinton to Hargreaves Segment is located within the Athabasca River Basin, and all six Alberta indicator species are known to occur within this basin. The Darfield to Black Pines Segment is located within the Lower North Thompson River Watershed, which is known to contain four of the BC indicator species (*i.e.,* bull trout/Dolly Varden, Chinook salmon, coho salmon and rainbow trout/steelhead). Hydrostatic testing will cause an interaction with fish and fish habitat indicators (riparian habitat, instream habitat and the indicator species found in the watershed from which test water is withdrawn).

The assessment of effects on fish and fish habitat has been conducted considering all the Project components in an integrated manner (*e.g.,* pipeline, temporary facilities, pump stations [including power lines], tanks and pipeline reactivation), since the components will have similar effect pathways (*i.e.,* riparian habitat, instream habitat and fish mortality and injury) on fish indicators and disaggregation of effects by Project component is not meaningful at an individual or population level for fish indicators.

The assessment of effects on fish and fish habitat for the Project as a whole is presented in Section 7.2.7. Table 7.2.7-3 and accompanying discussion in Section 7.2.7.6 provide an evaluation of potential residual effects of pipeline reactivation activities on fish indicators. Pipeline reactivation activities in Jasper National Park along the Hinton to Hargreaves Segment will follow the Jasper National Park Operations and Maintenance Environmental Protection Plan (TERA 2009).

7.7.7 Vegetation

Sections 7.2.9.1 and 7.2.9.2 provides the assessment indicators, measurement endpoints and spatial boundaries for the assessment of potential effects of pipeline reactivation activities on vegetation.

7.7.7.1 Ecological Context

Activities that may require clearing of land have the potential to affect vegetation. The pipeline reactivation includes MLBV locations that may require clearing of previously disturbed land. MLBV locations on the Hinton to Hargreaves Segment may be on the reclaimed TMX Anchor Loop right-of-way which was reclaimed and seeded with a native seed mix more than 5 years ago. The MLBV locations on the Darfield to Black Pines Segment may be on a right-of-way reclaimed decades earlier. Therefore, native vegetation is likely to have revegetated the right-of-way and may provide potential habitat for rare plant and lichen species. The introduction and spread of weeds has the potential to occur during any anthropogenic disturbance and, therefore, must be considered with the reactivated segments.

Section 7.2.9.3 provides further details on ecological context.

7.7.7.2 Potential Effects and Mitigation Measures

Identified Potential Effects

Potential effects associated with the reactivation of pipeline segments on vegetation are listed in Table 7.7.7-1. These interactions are based on the results of the literature review and desktop analysis as well as the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.7.7-1 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines as described in Section 7.2.9.4. Pipeline reactivation activities in Jasper National Park along the Hinton to Hargreaves Segment will follow the Jasper National Park Operations and Maintenance Environmental Protection Plan (TERA 2009).

TABLE 7.7.7-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON VEGETATION

Potential Effect	Pipeline Reactivation Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
1. Vegetation Indicator – Vegetation Communities of Concern				
1.1 Alteration of native vegetation	All	Footprint	• See recommended mitigation measures outlined in Table 7.2.9-3 Vegetation.	• Incremental alteration of the composition of native vegetation.

TABLE 7.7.7-1 Cont'd

Potential Effect	Pipeline Reactivation Segment(s)	Spatial Boundary[1]	Key Recommendations/Mitigation Measures [EPP Reference][2]	Potential Residual Effect(s)
2. Vegetation Indicator – Plant and Lichen Species of Concern				
2.1 Loss or alteration of rare plant and lichen occurrences	All	LSA	• See recommended mitigation measures outlined in Table 7.2.9-3 Vegetation.	• Some disturbance or alteration of a rare plant or lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site. • If rare plant or lichen sub-populations are located near the MLBV installation/automation location they may be affected by changes in hydrology or light levels.
3. Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-native Species Identified as a Concern				
3.1 Weed introduction and spread	All	RSA	• See recommended mitigation measures outlined in Table 7.2.9-3 Vegetation.	• Weed introduction and spread.

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.
2 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.7.7.3 Potential Residual Effects

The potential residual environmental effects on vegetation indicators as a result of pipeline reactivation activities (Table 7.7.7-1) are:

- incremental alteration of the composition of native vegetation;
- some disturbance or alteration of a rare plant or lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site;
- if rare plant and lichen sub-populations are located near a MLBV location they may be affected by changes in hydrology or light levels; and
- weed introduction and spread.

7.7.7.4 Significance Evaluation of Potential Residual Effects

Table 7.7.7-2 provides a summary of the significance evaluation of the potential residual environmental effects of pipeline reactivation activities on vegetation. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.7.7-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF PIPELINE REACTIVATION AND ASSOCIATED ACTIVITIES ON VEGETATION

Potential Residual Effects	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Vegetation Indicator – Vegetation Communities of Concern									
1(a) Incremental alteration of the composition of native vegetation.	Negative	Footprint	Short-term	Isolated	Short to medium-term	Low	High	High	Not significant
2. Vegetation Indicator – Plant and Lichen Species of Concern									
2(a) Some disturbance or alteration of a rare plant or lichen occurrence, if avoidance is not practical and mitigation measures do not completely protect a site.	Negative	Footprint	Short-term	Isolated	Medium to long-term	Medium	Low	High	Not significant

TABLE 7.7.7-2 Cont'd

Potential Residual Effects		Impact Balance	Spatial Boundary[1]	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[2]
2(b)	If rare plant and lichen sub-populations are located near a MLBV location they may be affected by changes in hydrology or light levels.	Negative	LSA	Short-term	Isolated	Short to medium-term	Low	Low	High	Not significant
3.	Vegetation Indicator – Presence of Infestations of Provincial Weed Species and Other Invasive Non-native Species Identified as a Concern									
3(a)	Weed introduction and spread.	Negative	RSA	Short-term	Isolated	Short to medium-term	Low to medium	High	High	Not significant

Notes: 1 LSA = Vegetation LSA; RSA = Vegetation RSA.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

The significance evaluation of the potential residual effects vegetation communities of concern, the rare plant and lichen species of concern and the presence of infestations of Provincial weed species and other invasive non-native species identified as a concern indicators were determined to be generally the same for pipeline reactivation activities as for the construction and operation of pipelines (Section 7.2.9.6) (Table 7.7.7-2, points 1[a], 2[a], 2[b], 3[a]). The exceptions are the frequency of the events which is isolated, reversibility of alteration of native vegetation which is considered to be of short to medium-term and low magnitude given the disturbed areas will be very small and likely located in previously disturbed areas. In addition, the probability of effects on plant and lichen species of concern is low for the reactivated segments because the probability of rare plant or lichen species revegetating the previously disturbed right-of-way is low. Table 7.4.9-2 and the accompanying discussion in Section 7.4.9.4 provide an evaluation of potential residual effects of the pipeline reactivation activities and their significance on the applicable vegetation indicator.

7.7.7.5 Summary

As identified in Table 7.7.7-2, there are no situations where there is a high probability of occurrence of a permanent or long-term residual environmental effect on the vegetation indicators of high magnitude that cannot be technically or economically mitigated. Consequently, is it concluded that the residual environmental effects arising from the pipeline reactivation and associated activities on vegetation will be not significant.

7.7.8 Species at Risk

The reactivation of pipeline segments may affect fish, vegetation and wildlife species at risk. Section 7.2.11 provides a discussion of the fish and wildlife species used as indicators for species at risk. Vegetation species at risk are considered under the plant and lichen species of concern indicator. Although not all species at risk are discussed explicitly under each indicator, potential Project effects were assessed in consideration of all species at risk. The indicators used to represent fish and fish habitat, vegetation and wildlife and wildlife habitat were carefully selected to ensure that the full range of potential Project effects on species at risk was addressed and mitigation measures to reduce these effects will apply to all species at risk, not just the indicators. Section 7.2.7 Fish and Fish Habitat, Section 7.2.9 Vegetation and Section 7.2.10 Wildlife and Wildlife Habitat provide the significance rationale for applicable indicator species. No significant adverse effect on species at risk has been identified as a result of the pipeline and facilities component of the Project.

7.8 Effects Assessment - Decommissioning and Abandonment

The NEB defines decommissioning as the permanent cessation of the operations of a pipeline without discontinuance of service, abandonment as the permanent cessation of the operation of a pipeline which results in the discontinuance of service and deactivation as to remove temporarily from service. The abandonment of a facility requires an application to the NEB under Section 74 of the *NEB Act*, as described in Guide B of the NEB *Filing Manual*.

It is difficult at this time to predict when or how the pipeline and facilities will be decommissioned or abandoned at the end of the Project's useful life. However, it can be anticipated that any of the following three scenarios may occur during pipeline decommissioning or abandonment: pipeline removal, abandonment-in-place or a combination of abandonment-in-place and pipeline removal. The existing TMPL has been successfully operating for 60 years and will be safe and reliable for many more years as a result of continuing proactive maintenance and integrity programs. The useful life of the Project will be as long or longer.

Trans Mountain is participating in and will comply with the process established by Stream 3 of the NEB Land Matters Consultation Initiative and Reasons for Decision [RH-2-2008]. In addition, a Preliminary Abandonment Plan is provided in Section 12.0 of Volume 4C, providing a discussion of the abandonment planning strategy for the pipelines and facilities to be constructed for TMEP. The plan discusses general activities for the types of facilities that would be abandoned in place, abandoned in place with special treatment or removed. The plan also discusses general reclamation objectives and principles that would be applied during abandonment to return the right-of-way and facility sites to a state comparable with the surrounding environment.

Current and future land use for the Project will be one of the most important factors in the determination of pipeline abandonment rationale. It is unlikely that any one abandonment technique will be appropriate for all land uses and as per consultation with affected parties, the decision to abandon or remove the pipeline and any associated infrastructure, including facilities and access roads, will be made on a site-specific basis and at the time of abandonment.

The methods of abandonment that will ultimately be implemented for the pipeline segments and facilities constructed for the Project will be determined at the time of the planning for abandonment and will be based on the most current body of scientific knowledge and accepted industry practices. It is expected that most of the pipeline will be abandoned in place; however, land use considerations and other factors may lead to pipeline segments being removed.

Current and future land use will be one of the most important factors in the determination of pipeline abandonment rationale. It is unlikely that any one abandonment technique will be appropriate for all land uses and the decision to abandon in place, abandon in place with special measures, or remove pipeline segments will be made on a site-specific basis and after consultation with affected parties and at the time of abandonment.

Environmental issues associated with potential abandonment methodologies such as ground subsidence, soil erosion and soil and water contamination may be regarded on a site-specific basis in determining the most appropriate abandonment methodology. Additionally, an assessment will be conducted to determine if there is any contamination of the associated land and, if warranted, special soil handling and remediation procedures would be implemented. Any lands disturbed by physical activities will be reclaimed to the appropriate land use at that time. For the Project, which is not expected to be abandoned for another 50-70 years, mitigation to address the environmental issues associated with pipeline abandonment and the determination of significance for any of the potential remaining effects cannot be meaningfully or realistically assessed at this time. The significance of any effects remaining following mitigation, including the significance of cumulative effects, will be determined and provided at the time Trans Mountain files for abandonment.

The reclamation objectives or principles to be applied to abandonment of the pipeline segments and facilities constructed for the Project will be in accordance with legislative and regulatory requirements in place at that time and likely similar to those required for Project construction. The primary goal of the reclamation is to stabilize and revegetate affected lands such that they will, in time, achieve productivity equivalent to the adjacent land use, ensuring the ability of the land to support various land uses.

The process of reclamation post-abandonment will likely involve a combination of measures such as: topsoil and root zone material salvage; subsoil conditioning and grade and drainage re-establishment; topsoil and root zone material replacement; installation and maintenance of temporary and permanent erosion and sediment control measures; and revegetation. Parameters such as vegetation, soil and landscape will be used as criteria to measure the degree of reclamation success, ensuring that land productivity is equivalent to the adjacent lands. Where no known or visible limitations to normal management, access, soil productivity and ecosystem function are evident during the evaluation, land reclamation will be determined to be successful.

Future decommissioning or abandonment activities will require prior approval by the NEB and other applicable regulatory authorities. Information regarding abandonment costs are provided in Section 2.0 of Volume 2. Volume 4C, Project Design and Execution – Operations and Maintenance, Section 12.0 provides additional details on abandonment plans.

7.9 Accidents and Malfunctions

Accidents and malfunctions are unplanned events that could result in significant adverse effects to human health, property or the environment, but are unlikely to occur. While accidents and malfunctions are predicted to be unlikely for the Project, the potential consequences are evaluated so that emergency response and contingency planning can be identified to ensure the risk is further mitigated.

7.9.1 Assessment Indicators and Measurement Endpoints

Indicators considered in the assessment of accidents and malfunctions include those indicators previously described for the environmental elements in Sections 7.2 to 7.7. The measurement endpoints for accidents and malfunctions consist of qualitative assessment of potential residual effects of accidents and malfunctions.

7.9.2 Spatial Boundaries

The spatial boundaries used in the effects assessment of accidents and malfunctions considered the applicable environmental element LSAs and RSAs as described in Sections 7.2 to 7.7. In general, the LSA is the ZOI in which environmental indicators are most likely to be affected by the construction and operations of the Project. The RSA is considered the area where the direct and indirect influence of other land uses and activities could overlap with Project effects and cause cumulative effects on the environmental indicator.

7.9.3 Potential Effects and Mitigation Measures

<u>Identified Potential Effects</u>

As stated in the NEB *Filing Manual* (NEB 2013a), an ESA must identify and assess the effects on workers, the public and biophysical and socio-economic elements of all potential accidents and malfunctions. Events causing accidents and malfunctions could include pipeline and equipment failure; human error; natural perils such as tornadoes, floods, hurricanes or earthquakes, and terrorism or other criminal activities.

Trans Mountain is committed to keeping their pipelines safe, and protecting their employees, the public and the environment. Trans Mountain strives to safeguard their facilities and to meet or exceed all applicable federal, provincial and local safety legislation.

Pipelines are a safe and efficient method of transporting large volumes of liquid products over long distances (Canadian Energy Pipeline Association 2013). However, incidents such as damage to the pipeline, operator error and vandalism could occur. To ensure the continued safe and reliable operation of its pipelines, Trans Mountain uses a multi-layered approach to pipeline safety that encompasses integrity management, damage prevention and emergency response programs.

The potential effects associated with accidents and malfunctions on socio-economic elements are provided in Volume 5B. The potential effects associated with accidents and malfunctions during marine transportation are provided in Volume 8A. The potential direct and indirect effects of an operational pipeline or marine spill are evaluated in Volumes 7 and 8A, respectively, including the risk of a spill, the anticipated spill response and the potential effects for various spill scenarios. Events causing accidents and malfunctions from natural perils such as tornadoes, floods, hurricanes and earthquakes are discussed in Section 7.10 Changes to the Project Caused by the Environment. The potential effects associated with a large spill reaching the Fraser River and estuary and a small spill during loading at the Westridge Marine Terminal are provided in Volume 7.

Potential effects associated with the construction and operations of the proposed pipeline and facilities on the environmental indicators are listed in Table 7.9-2. These interactions are based on the results of the literature review, desktop analysis, engagement with Aboriginal communities, consultation with landowners, regulatory authorities, stakeholders and the general public (Section 3.0), and the professional experience of the assessment team.

A summary of mitigation measures provided in Table 7.9-2 was principally developed in accordance with Trans Mountain standards as well as industry and provincial regulatory guidelines including AENV (1988, 1994a), BC OGC (2010a), CAPP (1999, 2001) and NEB (2011). In addition, these measures have been considered acceptable by the NEB for past pipeline projects for Spectra Energy (NEB 2008), Terasen Pipelines (NEB 2006) and NOVA Gas Transmission Ltd. (NEB 2010a-f).

Industry best practice technology, safety measures and contingency plans will also be used to reduce the probability and magnitude of accidents occurring and having substantial adverse effects. However, if an accident or malfunction does occur, an effective response plan will reduce the effects and associated risks. Trans Mountain adopts KMC's plans and policies for the purposes of the Project. Management systems and programs required under the *National Energy Board Onshore Pipeline Regulations* (*NEB OPR)* are listed below in Table 7.9-1.

TABLE 7.9-1

MANAGEMENT SYSTEMS AND PROGRAMS REQUIRED UNDER THE *NEB OPR*

Program	*NEB OPR* Section	Purpose of Program	Equivalent Trans Mountain Document
Emergency Management Program	Section 32	To ensure appropriate emergency preparedness and response.	• KMC Emergency Response Plan (on file with the NEB) • KMC Incident Command System (ICS) Guide • KMC Terminal Emergency Response Plan • KMC Westridge Marine Terminal Emergency Response Plan
Integrity Management Program	Section 40	To ensure the pipeline system continually operates within its design parameters.	• KMC Canadian Integrity Management Program (on file with the NEB) • KMC Facility Integrity Management Program (on file with the NEB)
Safety Management Program	Section 47	To protect workers and the public from occupational and process standards.	• KMC Contractor (Environmental/Safety) Manual (on file with the NEB) • KMC Health and Safety Standards Manual (on file with the NEB) • KMC Knowledge and Experience Enhancement Program (KEEP Canada Practice) (on file with the NEB)
Security Management Program	Section 47.1	To protect people, property and the environment from malicious damage.	• KMC has in place a Kinder Morgan Canadian Operations Facilities Security Plan that will be implemented for the Project (as per the NEB *Filing Manual*, companies are not to file their security documents electronically, although they need to be available for examination by the NEB during audits, inspections or other NEB regulatory activities) • KMC has in place site specific security plans for each district and terminal • KMC Emergency Response Program (on file with the NEB)
Environmental Protection Program	Section 48	To avoid or reduce adverse effects on the environment.	• Pipeline EPP (Volume 6B) • Facilities EPP (Volume 6C) • Westridge Marine Terminal EPP (Volume 6D) • KMC Contractor (Environmental/Safety) Manual (on file with the NEB) • KMC Environmental Standards and Guidelines

TABLE 7.9-2

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF ACCIDENTS AND MALFUNCTIONS DURING PIPELINE AND FACILITIES CONSTRUCTION AND OPERATIONS

Potential Effect	Project Component	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
1. Small spill of hazardous materials during construction and maintenance activities	All	Wildlife LSA and Aquatics LSA	<u>Spill Prevention</u> • Follow spill prevention measures provided in Section 43: Environmental Requirements – General and Section 45: Environmental – Spill Prevention and Control of the KMC Contractor (Environmental/Safety) Manual, on file with the NEB. • Do not store fuel, oil or hazardous material within 300 m of a watercourse/wetland/lake [Section 7.0]. • Maintain all appropriate spill equipment at all work sites. Assess the risk of resource-specific spills to determine the appropriate type and quantity of spill response equipment and materials to be stored on-site and a suitable location for storage (see Emergency Response Plan in Section 3.5 of Volume 4C) [Section 7.0]. • Store all hazardous substances and fuels in proper containment systems, to prevent release to the environment. Handle all hazardous materials in accordance with applicable WHMIS protocols [Section 7.0]. • Ensure that during construction no fuel, lubricating fluids, hydraulic fluids, methanol, antifreeze, herbicides, biocides, or other chemicals are dumped on the ground or into watercourses/wetlands/lakes. In the event of a spill, implement the Spill Contingency Plan [Section 7.0]. • Place an impervious tarp or drip tray underneath equipment/vehicles when servicing equipment/vehicles with the potential for accidental spills (*e.g.,* oil changes, servicing of hydraulic systems) [Section 7.0]. • Ensure that bulk fuel trucks, service vehicles and pick-up trucks equipped with box-mounted fuel tanks carry spill prevention, containment and clean-up materials that are suitable for the volume of fuels or oils carried. Carry spill response supplies on bulk fuel and service vehicles that are suitable for use on land and water (*i.e.,* sorbent pads, sorbent boom and rope) [Section 7.0]. • Ensure that operators and on-site construction foremen are trained to contain spills or leakage from equipment [Section 7.0]. The KMC Knowledge and Experience Enhancement Program (KEEP Canada Practice), on file with the NEB, is designed to ensure Trans Mountain employees are competent in their work and can work safely to protect themselves, the public and the environment. • Employ the following measures to limit the risk of fuel spills in water. Where equipment refuelling is necessary within 100 m of a watercourse/wetland/lake [Section 7.0]: - all containers, hoses, nozzles are free of leaks; - all fuel nozzles are equipped with automatic shut-offs; - operators are stationed at both ends of the hose during fuelling unless the ends are visible and readily accessible by one operator; and - fuel remaining in the hose is returned to the storage facility. • Do not wash equipment or machinery in watercourses/wetlands/lakes. Control wastewater from construction activities, such as equipment washing or concrete mixing, to avoid discharge directly into any body of water [Section 7.0].	• Inadvertent small spills could result in contamination or alteration of: - surface or groundwater quality (Section 7.2.3 Water Quality and Quantity); - instream or riparian habitat and fish mortality or injury (Section 7.2.7 Fish and Fish Habitat); - wetland function (Section 7.2.8 Wetland Loss or Alteration); - plants and ecological communities (Section 7.2.9 Vegetation); and - wildlife and wildlife habitat (Section 7.2.10 Wildlife and Wildlife Habitat). • No residual effects identified for soil and soil productivity due to effectiveness of clean up measures.

TABLE 7.9-2 Cont'd

Potential Effect	Project Component	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
1. Spill of hazardous materials during construction and maintenance activities (cont'd)	All	Wildlife LSA and Aquatics LSA	In the Event of a Spill • Implement the Contamination Discovery Contingency Plan in the event contaminated soils are encountered during construction [Appendix B]. • In the event of a spill, implement the Spill Contingency Plan [Appendix B]. • Report spills immediately to the Inspector(s) who will, if warranted, notify Trans Mountain for reporting to the appropriate regulatory authorities in accordance with the Spill Contingency Plan [Section 7.0 and Appendix B]. • Clean up and document spill in accordance with the *NEB Remediation Process Guide* (NEB 2011).	• See above.
2. Fire during construction and operations	All	Wildlife RSA	Fire Prevention • An environmental education program (Level II and III training) will be developed and implemented by the Trans Mountain Environmental Team to ensure that all Trans Mountain staff and contractors will be informed of the environmental and socio-economic requirements and sensitivities regarding the Project prior to arrival on the pipeline construction right-of-way, ancillary sites or associated component sites [Section 3.0]. • Apply the KEEP Canada Practice to ensure Trans Mountain employees are competent in their work and can work safely to protect themselves, the public and the environment. • Notify the appropriate regulatory authority prior to commencement of burning slash. When the fire risk is varying and when required, obtain and record the fire ratings daily to determine whether it is safe to burn. During slash disposal activities, maintain communication on a daily basis regarding time of ignition, location, extent and anticipated duration of burning activities [Section 8.1]. Slash burning will not be conducted in the Lower Mainland or at the Westridge Marine Terminal. • Comply with local government bylaws, the *Forest and Prairie Protection Act* (Alberta), the *Open Burning Smoke Control Regulation* (BC) and the *Forest Fire Prevention and Suppression Regulation* (BC) when burning slash [Section 7.0]. • Avoid locating burn piles on peat-rich soils in order to limit the risk of residual fires after construction. Locate burn piles on exposed soils (*i.e.*, where topsoil/root zone material salvage has occurred) [Section 8.1]. • Burn only when the fire hazard is at acceptable levels. No burning is to be conducted during high winds [Section 8.1]. • Monitor burning at all times and prevent fire from spreading off the construction right-of-way. Extinguish burning embers before leaving the site and monitor burn sites to ensure no smouldering debris remains. Push unburned stumps along the edge of the construction right-of-way after attempting to burn them [Section 8.1]. • Firefighting equipment and a Fire Watch must be supplied by the contractor and must be present while performing any hot work (Section 13: Fire Prevention and Protection of the KMC Contractor [Environmental/Safety] Manual). • Implement the fire prevention measures in Section 6.1.1 of KMC's Emergency Response Plan, on file with the NEB. • Ensure that slash burning crews have firefighting equipment on hand that is capable of controlling any fire that may occur as a result of their activities [Section 8.1].	• Despite vigilance, fires may adversely affect adjacent vegetation and in very rare situations, affect wildlife.

TABLE 7.9-2 Cont'd

Potential Effect	Project Component	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
2. Fire during construction and operations (cont'd)	All	Wildlife RSA	Fire Prevention (cont'd) • Burn piles must be spread and mixed with water or snow to ensure they are properly extinguished [Section 8.1]. • Conduct infrared scanning of burn piles to locate any hot spots [Section 8.1]. • Smoking is allowed in designated areas only. Designated smoking areas will be identified during the pre-job construction meeting or work permitting process (Section 13: Fire Prevention and Protection of the KMC Contractor [Environmental/Safety] Manual). • All activity inspectors and contractors' vehicles will carry firefighting equipment such as pulaskis, shovels, backpack pumps or components of a water delivery system (pump and hose) in sufficient quantities so that each worker has access to at minimum, one hand tool with which to carry out fire suppression work. In addition, all motorized equipment must carry a fully charged fire extinguisher. The Safety Manager or Safety Coordinator will ensure that fire extinguishers are present and fully charged [Appendix B]. Fire During Construction • Follow the fire suppression measures of the Fire Contingency Plan [Appendix B]. • Implement the Emergency Response Plan and Fire Contingency Plan in Section 3.5 of Volume 4C. Fire During Operations • Implement the above procedures, as applicable, to operations and maintenance activities.	• See above.
3. Damage to foreign utilities during construction and operations	All	Aquatics RSA	• Notify applicable companies for road, power line and foreign pipeline crossings, if required, by crossing and road use agreements [Section 4.0]. • Locate and flag all existing buried utility lines and cables to be crossed by the pipeline prior to the commencement of ground disturbance activities by using "one call" services or direct contact with utility owners [Section 7.0]. • Ensure construction personnel are properly trained in ground disturbance techniques. Apply the KEEP Canada Practice to ensure Trans Mountain employees are competent in their work and can work safely to protect themselves, the public and the environment. • Use flagging and signage at overhead line crossings to alert equipment operators of hazards. • Conduct construction activities near adjacent pipelines in compliance with all requirements of CSA Z662-11 and the *NEB OPR* for work close to an operating pipeline. • Prior to any equipment working on, or crossing over, an adjacent pipeline, first obtain a crossing permit from the operator for each specific location, detailing the conditions and limitations for each crossing. • During Project construction, maintain minimum separations between the pipe trench and adjacent pipes needed to protect the existing pipeline during construction of the Project, and allow for future remedial excavation work on either pipeline without affecting the other pipeline.	• Damage to utility lines could lead to contamination of soil or water depending on the location and severity of the rupture, and fires in the case of gas.
4. Release of drilling mud during HDD	New pipeline	Aquatics LSA	• Plan for and use the procedures for a HDD or other trenchless crossing in accordance with those provided in the Horizontal Directional Drilling/Trenchless Planning and Procedures Management Plan (see Appendix C) [Section 8.7.3]. • Cease trenchless crossing work immediately and refer to the Drilling Mud Release Contingency Plan (see Appendix B) in the event that an inadvertent release of drilling mud has occurred and the material is or may enter the watercourse or affect other sensitive environmental or land use features [Section 8.7.3].	• Release of drilling mud on land may affect soil productivity.

TABLE 7.9-2 Cont'd

Potential Effect	Project Component	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
4. Release of drilling mud during HDD (cont'd)	New pipeline	Aquatics LSA	• Follow the drilling mud frac-out monitoring and other measures outlined in the Drilling Mud Release Contingency Plan (see Appendix B) during horizontal directional drilling [Section 8.7.3]. • Assign the Inspector(s), Qualified Aquatic Environmental Specialist (QAES) or Qualified Environmental Professional (QEP) with expertise in the containment of inadvertent release of drilling mud and clean up to HDDs under a watercourse (see Drilling Mud Release Contingency Plan in Appendix B) [Section 8.7.1].	• Disturbance of vegetation or habitat could result during clean up and reclamation efforts following an HDD mud release on land or riparian areas. • Depending on the volume and location of a release, a release of HDD mud into a watercourse may affect aquatic ecosystems.
5. Transportation accidents	All	Wildlife RSA	• Establish speed limits, approved by Trans Mountain, on the construction right-of-way and access roads. Post signs stating the applicable speed limits for construction traffic to avoid wildlife injury and mortality, maintain soil structure and reduce dust [Section 7.0]. • An environmental education program (Level II and III training) will be developed and implemented by the Trans Mountain Environmental Team to ensure that all Trans Mountain staff and contractors will be informed of the environmental and socio-economic requirements and sensitivities regarding the Project prior to arrival on the pipeline construction right-of-way, ancillary sites or associated component sites. Environmental training at a minimum will include, at a minimum, the following: - the identification of sensitive features and valuable environmental components; - the process to follow should sensitive environmental features be located and/or disturbed during construction; - the expectation that speed limits and signage, flagging and/or fences delineating the environmental features shall be respected at all times; and - the established protocol for wildlife encounters. [Section 3.0]. • Use multi-passenger vehicles for the transportation of crews to and from the job sites, where feasible [Section 7.0]. • Follow recommendations in the Traffic and Access Control Management Plan [Appendix C of Volume 6B] and the Traffic Control Management Plan in Section 3.5 of Volume 4B, as well as the Public Traffic Control Plan to be developed by the contractor.	• A transportation accident may cause injury to wildlife or may result in fire or contamination of lands and water depending on the location and severity of the accident.
6. Use of explosives	New pipeline	Wildlife RSA	• Review safety protocols and procedures with construction workers working in the fly rock zone prior to commencement of blasting activity. Reduce the potential for injury from flying rock, by using sound warning calls and visually scan for wildlife in the blasting area. If wildlife is spotted within the blasting area, use measures recommended by the Wildlife Resource Specialist to displace wildlife prior to blasting [Section 8.3]. • Apply the KEEP Canada Practice to ensure Trans Mountain employees are competent in their work and can work safely to protect themselves, the public and the environment. • Utilize warning sirens, blasting mats, blasting controls and monitoring to reduce potential injury to wildlife [Section 8.3]. • Implement measures in the Blasting Management Plan in Section 3.5 of Volume 4B. • Transport explosives in accordance with the *Transport of Dangerous Goods Act* and other applicable provincial or federal legislation.	• Fly rock from blasting may cause injury to wildlife, while unintentional detonation of explosives could affect wildlife or aquatic ecosystems depending on the proximity to the detonated area.

TABLE 7.9-2 Cont'd

Potential Effect	Project Component	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
6. Use of explosives (cont'd)	See above	See above	• Store explosives on-site in compliance with permits and provincial or federal legislation. Ensure that explosives are stored in a secured container to minimize accessibility to wildlife and the public. • Handle the explosives in accordance with permits, certificates and provincial and federal legislation. • Use blast mats to minimize the risk of damage to property within the fly rock zone.	• See above.
7. Security risk	All	Wildlife LSA	<u>Construction</u> • Install locked gates at locations noted on the Environmental Alignment Sheets (Volume 6E) to block unauthorized travel along the construction right-of-way following clearing. Keep gates locked and assign security personnel, if warranted, to block access [Section 8.1]. • Install temporary fencing around construction camps and borrow sites to reduce the attraction of wildlife and to provide security for the site [Sections 10.0 and 11.0]. • During construction, Trans Mountain will implement the Security Program in Section 3.5 of Volume 4B. During operations, follow Section 10.0 Pipeline Security of Volume 4C. • In the event of a bomb threat, Trans Mountain will follow the Bomb Threat Action Checklist in Section 6.6 of KMC's Emergency Response Plan. • For any other breaches of security, Trans Mountain will follow the Breach of Security Action Checklist in Section 6.7 of KMC's Emergency Response Plan. <u>Operations</u> • Right-of-way surveillance is conducted in the form of aerial patrols and ground patrols to monitor for visible threats to pipeline integrity. Aerial patrol can prevent incidents by reporting unauthorized ground disturbance activities, as discussed in the KMC Canadian Integrity Management Program, on file with the NEB. • Ensure all facility sites are secured with locked fencing and are equipped with signage warning of the hazards related to the products on the site. Ensure all valves in remote facilities are locked or mechanically plugged and the local push buttons on motor operated valves are rendered inactive unless activated by secured switches (Section 6 of the KMC Facility Integrity Management Program, on file with the NEB). • During construction, Trans Mountain will implement the Security Program in Section 3.5 of Volume 4B. During operations, follow Section 10.0 Pipeline Security of Volume 4C. • In the event of a bomb threat, Trans Mountain will follow the Bomb Threat Action Checklist in Section 6.6 of KMC's Emergency Response Plan. • For any other breaches of security, Trans Mountain will follow the Breach of Security Action Checklist in Section 6.7 of KMC's Emergency Response Plan.	• Damage from criminal activity.

Note: 1 Detailed mitigation measures noted are outlined in the Pipeline EPP (Volume 6B). Similar measures appear in the Facilities EPP (Volume 6C) and Westridge Marine Terminal EPP (Volume 6D) but cross references have not been provided.

7.9.4 Potential Residual Effects

The potential residual environmental effects that could occur as a result of accidents and malfunctions during construction and operations of the pipeline and facilities (Table 7.9-2) are:

- contamination or alteration of surface or groundwater quality, riparian or instream habitat, fish mortality or injury, wetland function, plants and ecological communities, and wildlife and wildlife habitat due to small spills during construction;

- despite vigilance, fires may adversely affect adjacent vegetation and in very rare situations, affect wildlife;
- damage to utility lines could lead to contamination of soil or water depending on the location and severity of the rupture, and fires in the case of gas;
- release of drilling mud on land may affect soil productivity;
- disturbance of vegetation or habitat could result during clean up and reclamation efforts following an HDD mud release on land or riparian areas;
- depending on the volume and location of a release, a release of HDD mud into a watercourse may affect aquatic ecosystems;
- a transportation accident may cause injury to wildlife or may result in fire or contamination of lands and water depending on the location and severity of the accident;
- fly rock from blasting may cause injury to wildlife, while unintentional detonation of explosives could affect wildlife or aquatic ecosystems depending on the proximity to the detonated area; and
- damage from criminal activity.

7.9.5 Significance Evaluation of Potential Residual Effects

Where there are no standards, guidelines, objectives or other established and accepted ecological thresholds to define quantitative rating criteria or where quantitative thresholds are not appropriate, the qualitative method that is considered to be the appropriate method. Consequently, a qualitative assessment for accidents and malfunctions was determined to be the most appropriate method with the evaluation of significance of each of the potential residual effects relying on the professional judgment of the assessment team.

Table 7.9-3 provides a summary of the significance evaluation of the potential residual environmental effects associated with accidents and malfunctions during the construction and operations of the Project. The rationale used to evaluate the significance of each of the residual environmental effects is provided below.

TABLE 7.9-3

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF ACCIDENTS AND MALFUNCTIONS DURING PROJECT CONSTRUCTION AND OPERATIONS

	Potential Residual Effects	Impact Balance	Spatial Boundary	Temporal Context			Magnitude	Probability	Confidence	Significance[1]
				Duration	Frequency	Reversibility				
(a)	Contamination of surface or groundwater due to small spills during construction.	Negative	Water Quality and Quantity LSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
(b)	Contamination or alteration of habitat and fish mortality or injury due to small spills during construction.	Negative	Wildlife LSA and Aquatics LSA	Immediate	Accidental	Short to long-term	Low to high	Low	Moderate	Not significant
(c)	Despite vigilance, fires may adversely affect adjacent vegetation and in very rare situations, affect wildlife.	Negative	Wildlife RSA	Immediate	Accidental	Medium to long-term	Low to high	Low	Moderate	Not significant

TABLE 7.9-3 Cont'd

	Potential Residual Effects	Impact Balance	Spatial Boundary	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[1]
(d)	Damage to utility lines could lead to contamination of soil or water depending on the location and severity of the rupture, and fires in the case of gas.	Negative	Aquatics RSA	Immediate	Accidental	Immediate to short-term	Low to high	Low	Moderate	Not significant
(e)	Disturbance of vegetation/habitat could result during clean up and reclamation efforts following an HDD mud release on land or riparian areas.	Negative	Wildlife LSA	Immediate	Accidental	Medium to long-term	Low to high	Low	Moderate	Not significant
(f)	Depending on the volume and location of the release, a release of HDD mud on land may affect soil productivity or into a watercourse may affect aquatic ecosystems.	Negative	Water Quality and Quantity LSA	Immediate	Accidental	Immediate to medium-term	Low to high	Low	Moderate	Not significant
(g)	A transportation accident may cause injury to wildlife or may result in fire or contamination of lands and water depending on the location and severity of the accident.	Negative	Wildlife RSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
(h)	Fly rock from blasting may cause injury to wildlife, while unintentional detonation of explosives could affect wildlife or aquatic ecosystems depending on the proximity to the detonated area.	Negative	Wildlife RSA	Immediate	Accidental	Short to medium-term	Low to high	Low	Moderate	Not significant
(i)	Damage from criminal activity.	Negative	Wildlife LSA	Immediate	Accidental	Short to long-term	Low to high	Low	Moderate	Not significant

Note: 1 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Spills During Construction

Concerns regarding spills were raised during Aboriginal engagement and during most of the public information sessions, ESA Workshops and Community Workshops during public consultation. Many people engaged noted that the potential effects of spills, spill prevention and spill response were top concerns. While the effects of large spills during operations are discussed in Volume 7, this discussion focuses on small spills during construction and the potential impact on the environment. For the purposes of this assessment, a small spill is defined by Kinder Morgan's North American Standard as a spill under 5 gallons (18.9 L) which would not cause a significant environmental effect (*i.e.,* not into a watercourse). It should be noted that spills of all sizes and commodities are logged.

Companies regulated by the NEB are required to report on spills that could have a significant adverse effect on the environment regardless of size. An example of this is would be any release of hydrocarbons into a water body. of all reportable liquid spill incidents recorded by industry between 2008 and April 2013, less than one incident per year was a liquid release into a waterway, illustrating that spills potentially altering surface or groundwater are rare but not exceptionally uncommon (NEB 2013b).

Surface water or groundwater quality could be affected from a spill during construction. The severity of the effect would depend on the size and location of the spill. However, pipeline spill statistics demonstrate that the probability of a significant adverse residual effect is low. As discussed in Section 7.2.3.4, contamination of an aquifer may result if the spilled material migrates through the developed soil near the surface through the surficial materials into the first water-bearing unit. The rate of migration is dependent upon the permeability of the materials, presence or absence of fractures, the properties of the spilled contaminant (density, viscosity) and the vertical hydraulic gradients. A spill during the construction phase of the Project is likely to be noted quickly and be of small volume, and evidence suggests that the effects of most minor spills are localized. With the implementation of the spill prevention (*i.e.,* not storing fuel, oil or other hazardous materials within 300 m of a watercourse or waterbody) and response measures (*e.g.,* Spill Contingency Plan in Appendix B of the Pipeline EPP in Volume 6B) recommended in Table 7.9-2 and clean up and remediation measures, a spill potentially affecting surface or groundwater are considered to be of low to high magnitude and reversible in the short to medium-term. The probability of a spill contaminating groundwater or surface water is low (Table 7.9-3, point [a]). This adverse residual effect relates to the indicators of surface water and groundwater quality and quantity under Section 7.2.3 Water Quality and Quantity. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – contaminants released into surface water or groundwater resulting from an accidental spill during construction can be transported before the contaminants are either diluted to a safe level or remediated.
- Duration: immediate – the event causing contamination of surface or groundwater is a spill, the period of which is less than one day.
- Frequency: accidental – a spill causing contamination of surface or groundwater is rare during construction.
- Reversibility: short to medium-term – depending on the size of the spill.
- Magnitude: low to high – depending on the volume, location and contaminants released.
- Probability: low – due to mitigation measures in place to reduce the potential for spills and the emergency response measures to contain and clean up product.
- Confidence: moderate – based on the professional experience of the assessment team.

Spills during construction could potentially contaminate or otherwise alter aquatic habitat (*i.e.,* instream fish habitat, wetlands) or terrestrial habitat (*i.e.,* riparian fish and wildlife habitat, upland wildlife habitat, vegetation habitat, wetland habitat). Depending on the severity and location of the spill, residual effects are expected to be reversible in the short-term (*e.g.,* small terrestrial spill that affects only herbaceous vegetation) to long-term (*e.g.,* spill affecting forested wildlife habitat and may require clearing to effectively clean up and reclaim the site; cleared habitat can regenerate in the long-term). Similarly, the magnitude of residual effects of spills on habitat varies depending on the severity of the event and the habitat affected. For example, in the event of a spill such as a fuel truck rollover in a stream with high quality fish habitat, the adverse residual effects could be of high magnitude with long lasting ramifications to the health of the stream. With the implementation of spill prevention and response measures, events such as this rarely occur and even more rarely occur instream or where other sensitive habitats exist (*e.g.,* rare plant populations or habitat features important for wildlife species of concern). Therefore, the probability of the effect is low (Table 7.9-3, point [b]).

This adverse residual effect relates to the indicators of instream and riparian habitat, and fish mortality or injury under Section 7.2.7 Fish and Fish Habitat, wetland function under Section 7.2.8 Wetland Loss or Alteration, vegetation communities of concern and plant and lichen species of concern under Section 7.2.9 Vegetation, and indicator species under Section 7.2.10 Wildlife and Wildlife Habitat. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Wildlife LSA and Aquatics LSA – contaminants resulting from accidental spills may be confined to the location of the incident within terrestrial habitat or released into aquatic habitat and subsequently transported.
- Duration: immediate – the event causing contamination of aquatic or terrestrial habitat is a spill, the period of which is less than or one day.
- Frequency: accidental – a spill causing contamination or otherwise alter aquatic habitat is rare during construction.
- Reversibility: short to long-term – depending on the size of the spill.
- Magnitude: low to high – depending on the volume, location and contaminants released.

- Probability: low – due to mitigation measures in place to reduce the potential for spills and the emergency response measures to contain and clean up product.
- Confidence: moderate – based on the professional experience of the assessment team.

Fire During Construction

Restricting burning in areas with high fire hazard will be especially important during summer construction in the interior BC area, particularly if it is a dry year. Participants at the Blue River Community Workshop noted that a forest fire in the area could potentially shut down construction work, even if exemptions to burning restrictions are obtained. Participants at the Blue River Community Workshop also advised that emergency response capacity may be limited in the event of an accident due to capacity constraints. This may be the case with other small communities along the proposed pipeline corridor; however, Trans Mountain will work with emergency services to ensure that there is sufficient capacity to respond to a fire during construction and operations.

The significance of a fire will depend to a large extent on the location (*e.g.,* forest versus agricultural lands), size and what it consumes. Since small fires within the Footprint and off of the Footprint are of minor and moderate concern respectively, and can be extinguished quickly, they are not likely to cause a significant adverse residual effect. Large fires that spread off the Footprint and result in loss of vegetation or wildlife habitat are likely to be considered of high magnitude. With the implementation of mitigation measures (*e.g.,* construction crews having firefighting equipment and training) and the development of a Fire Contingency Plan (Appendix B of the Pipeline EPP in Volume 6B), the probability of large fires developing during pipeline construction is low (Table 7.9-3, point [c]).

This adverse residual effect relates to the indicators of vegetation communities of concern and plant and lichen species of concern under Section 7.2.9 Vegetation, and indicator species under Section 7.2.19 Wildlife and Wildlife Habitat. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Wildlife RSA – accidental fires could vary in size depending on the circumstances (*e.g.,* location, weather, level of preparation) and would generally be confined to the Wildlife LSA but in exceptional circumstances (grassland) could extend beyond the LSA to the RSA.
- Duration: immediate – the event causing effects on adjacent habitat is a fire, the period of which is generally less than or equal to two days.
- Frequency: accidental – fires resulting from construction or operations activities are rare.
- Reversibility: medium to long-term – affected habitat may take up to or longer than 10 years to recover from a fire depending on the species composition (*i.e.,* shorter for shrubs and grasses, longer for trees).
- Magnitude: low to high – depending on the size and location of the fire, and the sensitivity of the habitat affected.
- Probability: low – it is unlikely that a fire will occur.
- Confidence: moderate – based on the professional experience of the assessment team.

Damage to Utility Lines Could Lead to Interruption of Services and Fires in the Case of Gas

In the event of a rupture of a high-pressure gas line, the risk of explosion and risk to habitat could be considered of medium magnitude. Since high-pressure pipelines are easily located (as opposed to some low-pressure plastic distribution lines) and are of sufficient size and strength that rupture is extremely unlikely, the probability of an explosion of existing gas pipelines is low. Rupture of the existing Trans Mountain pipeline or another foreign pipeline during construction resulting in severe contamination to air or water could be considered a significant adverse effect. Trans Mountain will adhere to industry standards, legislation (*e.g.,* CSA Z662-11 and the *NEB OPR*) and company protocols and, therefore, the probability of a rupture of the existing Trans Mountain pipeline or another foreign pipeline is unlikely and, therefore, the potential for a significant adverse effect resulting from working in the vicinity of foreign pipelines is low (Table 7.9-3, point [d]). The potential effects of a large rupture on air or water are discussed further in Volume 7. This adverse residual effect relates to the indicators of soil productivity and soil contamination under Section 7.2.2 Soil and Soil Productivity, surface and groundwater quality under Section 7.2.3 Water Quality and Quantity, vegetation communities of concern and plant and lichen species of concern under Section 7.2.9 Vegetation and indicator species under Section 7.2.10 Wildlife and Wildlife Habitat. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Aquatics RSA – the effects resulting from accidental ruptures of water lines or foreign pipelines range from small terrestrial spills (Footprint) to contamination of surface or groundwater (Aquatics RSA) to large fires (Wildlife RSA), depending on the product in the line.
- Duration: immediate – the event causing a rupture or damage to utility lines is an accident, the period of which is less than or equal to two days.
- Frequency: accidental – rupture of or damage to utility lines during construction is rare.
- Reversibility: immediate to short-term – depending on the length of time needed for clean up and reclamation of the residual effect caused by damage to or rupture of a utility line.
- Magnitude: low to high – depending on the type and location of the utility line as well as the sensitivity of habitats affected by the ruptured utility line.
- Probability: low – it is unlikely that a rupture or damage to a utility line will occur.
- Confidence: moderate – based on the professional experience of the assessment team.

Inadvertent Release of Drilling Mud During Horizontal Directional Drilling

A release of drilling mud during an HDD onto land could potentially alter upland or riparian habitat. A drilling mud release is relatively benign since the bentonite clay is inert and can often be cleaned up and the areas affected by the release readily reclaimed. In the event that a drilling mud release on to land occurs during a trenchless crossing, the Drilling Mud Release Contingency Plan of the Pipeline EPP will be implemented which includes measures for clean up of the site. Schmidt *et al.* (2001) evaluated the effect of a release of mud during HDD on wetlands at five sites and determined that none displayed significant long-term effects as a result of bentonite discharge and further noted that the level of observed effect was in part related to the nature of clean up procedures. The reversibility of the adverse residual effect of a terrestrial (upland or riparian area) HDD release will depend on the length of time it takes vegetation to recolonize the area disturbed by the mud and clean up activities and varies from medium to long-term (Table 7.9-3, point [e]).

Instream releases of drilling mud occur less frequently than terrestrial releases. This is primarily due to the layout of directional drill paths which are commonly much longer than the width of the watercourse and have shallower depths of cover near the upland drill entry and exit locations. The depth of cover along an HDD path often reaches its maximum directly under the watercourse. The introduction of a clay-based drilling mud into the environment will have variable effects depending on the location, volume released and the level of clean up that is appropriate. Monitoring throughout an HDD program allows detection of a release of drilling mud soon after a release occurs. The ability to stop the flow of mud quickly also aids in limiting the total volume of drilling mud that could be released. Since the total volumes of drilling mud released during an inadvertent release are generally limited, drilling mud released into a watercourse will dissipate into a watercourse in a short period. An instream drilling mud release is reversible in the immediate to medium-term, depending on the volume of the release and flow rates of the watercourse (Table 7.9-3, point [f]).

These adverse residual effects relates to the indicators of surface and groundwater quality under Section 7.2.3 Water Quality and Quantity; instream habitat, injury and mortality, and fish indicator species under Section 7.2.7 Fish and Fish Habitat; vegetation communities of concern under Section 7.2.9 Vegetation; and wildlife indicator species under Section 7.2.10 Wildlife and Wildlife Habitat. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Wildlife LSA - drilling mud releases may be confined to land (point [e]); Water Quality and Quantity LSA – drilling mud releases may be transported via surface water or groundwater.
- Duration: immediate – the event causing the residual effect is an inadvertent release of drilling mud during HDD, the period of which is less than or equal to two days.
- Frequency: accidental – the release of drilling mud is relatively rare, being confined to segments of pipeline construction requiring HDD.
- Reversibility: medium to long-term (terrestrial mud release, point [e]) – depending on the length of time it takes for vegetation to recolonize the area disturbed by the mud; immediate to medium-term (instream release, point [f]) – depending on the volume of the release and flow rates of the watercourse.
- Magnitude: low to high – depending on the location and quantity of drilling mud released.
- Probability: low – Trans Mountain will implement mitigation measures during HDD operations to prevent drilling mud release.
- Confidence: moderate – based on the professional experience of the assessment team.

Transportation Accident During Construction

Public safety during construction was noted as a concern during the Chilliwack Community Workshop. Increased traffic congestion during construction that may lead to an increased risk of traffic accidents was also raised during the Valemount Community Workshop. Transportation accidents arising from increased traffic on major roads associated with Project construction will be mitigated by implementing the measures in Table 7.9-2, including the use of a Traffic and Access Control Management Plan (Appendix C of the Pipeline EPP in Volume 6B). The availability and capacity of emergency services (*e.g.,* fire, ground and air ambulance) in the Project area are described in Section 5.5.6 and Section 5.8.6.3 of Volume 5B.

This adverse residual effect relates to the indicators of soil productivity and soil contamination under Section 7.2.2 Soil and Soil Productivity, surface water quality under Section 7.2.3 Water Quality and Quantity, vegetation communities of concern and plant and lichen species of concern under Section 7.2.9 Vegetation and wildlife indicator species under Section 7.2.10 Wildlife and Wildlife Habitat.

A transportation accident arising from increased traffic on major roads associated with Project construction activities would likely be considered of high magnitude if the accident resulted in death to a wildlife species of concern, damage to critical habitat or severe contamination of lands or water. However, the probability of a vehicle accident having a significant effect is low (Table 7.9-3, point [g]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Wildlife RSA – transportation accidents during construction activities may result from commuting to and from the work site.
- Duration: immediate – the event causing potential injury to wildlife is a transportation accident, the period of which is less than two days.
- Frequency: accidental – transportation accidents during construction and any associated residual effects are rare.
- Reversibility: short to medium – some accidents affecting wildlife may result in minor injuries from which the individual can readily recover; however, in situations where the individual succumbs to its injuries, it will take more than one year to replace the individual within the species population.
- Magnitude: low to high – depending on the type and severity of effects associated with the outcome of a transportation accident.

- Probability: low – it is unlikely that a transportation accident will occur.
- Confidence: moderate – based on the professional experience of the assessment team.

Blasting During Construction

Blasting will be required at certain places along the proposed pipeline corridor to install the new pipe. Mitigation measures in Table 7.9-2 will be implemented to reduce the risk of injury from fly rock or accidental detonation. Emergency response plans will respond in the unlikely event of an injury. The availability and capacity of emergency services (*e.g.,* fire, ground and air ambulance) in the Project area are described in Section 5.5.6 and Section 5.8.6.3 of Volume 5B. This adverse residual effect is relevant to the indicators of surface water quality under Section 7.2.3 Water Quality and Quantity, fish mortality or injury and fish indicator species under Section 7.2.7 Fish and Fish Habitat, and indicator species under Section 7.2.10 Wildlife and Wildlife Habitat.

Typically, fly rock from the detonation of explosives during blasting will not result in a significant adverse residual effect if safety measures and protocols are adhered to, including the use of blasting mats to reduce or eliminate fly rock. Noise associated with general construction activity in the vicinity of the blasting area coupled with the warning calls prior to detonation will likely displace wildlife from the fly rock zone. The probability of serious injury or death of wildlife is low. Blasting activities were conducted during construction of the TMX Anchor Loop Project and no adverse effects to the environment were noted (TERA 2009a).

The significance of an unintentional detonation of explosives will depend on the location of the detonation and its proximity to sensitive wildlife and sensitive aquatic ecosystems. An accidental detonation of explosives in areas devoid of fish-bearing watercourses and habitat for wildlife species at risk is not likely to cause a significant adverse residual effect. Given the proper implementation of mitigation measures during the transport, storage and handling of explosives, the probability of an unintentional detonation is low (Table 7.9-3, point [h]).

The use of explosives during blasting along the proposed pipeline corridor will not affect the operations or integrity of the existing Trans Mountain pipeline or other infrastructure. Small scale test blasts will be conducted to demonstrate the blast performed as per plan and complies with allowable vibration levels measured at the infrastructure of concern. Additional detail on blasting is provided in Volume 4A. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Wildlife RSA – fly rock or unintentional detonation could cause injury or damage to habitat beyond the Footprint.
- Duration: immediate – the event causing injury or damage to habitat from fly rock from blasting or an unintentional detonation is an accident, the period of which is less than two days.
- Frequency: accidental – injury from blasting fly rock or an unintentional detonation of explosives is rare.
- Reversibility: short to medium – an accident from fly rock or unintentional detonation may result in minor injuries to wildlife from which the individual can readily recover; however, in situations where the individual succumbs to its injuries, it will take more than one year to replace the individual within the species population.
- Magnitude: low to high – depending on the type and severity of effects associated with the outcome of an accident associated with explosives.
- Probability: low – it is unlikely that an accident associated with explosives will occur.
- Confidence: moderate – based on the professional experience of the assessment team.

Damage from Criminal Activity

The issue of security risks related to criminal activity was raised during consultation at the Edmonton West, Edson, Chilliwack and Burnaby Community Workshops. Participants in these workshops were concerned that opponents of the Project may pose a security risk to the existing TMPL system and/or the Project.

KMC has in place a Kinder Morgan Canadian Operations Facilities Security Plan as required by Section 47.1 "Security Management Program" of the *NEB OPR* and in compliance with CSA Z246.1-09 which will be supplemented with a TMEP-specific Security Program. Additional mitigation measures (*e.g.,* the Traffic and Access Control Management Plan in Appendix C of the Pipeline EPP [Volume 6B]) are provided in Table 7.9-2 to prevent vandalism, theft and damage to the existing and proposed infrastructure.

Despite security measures currently in place and proposed for the Project, it is possible that a security incident could still occur during construction or operations. A security incident such as a bomb threat which could cause a rupture of the pipeline and a product release, injury or mortality of wildlife, fire or severe contamination of aquatic ecosystems, could potentially be considered a significant adverse residual effect. The probability of such an incident occurring is low (Table 7.9-3, point [i]). The potential effects of a product release during operations are discussed further in Volume 7. Other security incidents such as theft or minor vandalism, while illegal, would likely be of low magnitude and reversible in the immediate to short-term if repair or replacement is relatively easy.

Engagement with communities along the proposed pipeline corridor will be ongoing, including discussions about how Trans Mountain addresses pipeline safety and how the community may assist, such as reporting suspicious behaviour around the pipeline or facilities, if observed. Trans Mountain will work with emergency services (*e.g.,* fire and police) to ensure that there are resources available to respond to a major security incident such as a bombing or fire, should it occur during construction or over the lifetime of the Project.

This adverse residual effect is relevant to the indicators of surface water quality under Section 7.2.3 Water Quality and Quantity, fish mortality or injury and fish indicator species under Section 7.2.7 Fish and Fish Habitat, and wildlife indicator species under Section 7.2.10 Wildlife and Wildlife Habitat. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Wildlife LSA – the effects of a security incident could be confined to the Footprint or extend into the Wildlife LSA.
- Duration: immediate – acts of criminal activity would likely be conducted as quickly as possible in order to avoid being seen by a worker or the general public (*i.e.,* less than or equal to two days).
- Frequency: accidental – although the act of a security incident such as vandalism, theft, damage to the proposed or existing pipeline and facilities, or fire would be deliberate, it is expected to occur rarely, if at all.
- Reversibility: short to long-term – an act of vandalism resulting in minor disturbance to the environment may be remediated during the construction phase or within any one year during the operations phase (short-term), while other acts (*e.g.,* a bombing) resulting in injury or death to wildlife may take several years to replace the individual within the species population, depending on the species (medium-term). Damage to habitat from a fire would be reversible in the long-term.
- Magnitude: low to high – depending on the type and severity of effects caused by the security incident.
- Probability: low – the probability of a security incident occurring is based on actual location.
- Confidence: moderate – based on the professional experience of the assessment team.

7.9.6 Summary

As identified in Table 7.9-3, the probability of a significant residual environmental effect arising from accidents and malfunctions as a result of the construction and operations of the Project is low.

7.10 Changes to the Project Caused by the Environment

Trans Mountain has been operating a pipeline system and associated facilities in Canada for over 60 years and is aware of the typical, as well as the range of atypical, environmental conditions experienced along their system. This knowledge is reflected in the engineering design and mitigation measures proposed to address these environmental conditions. In particular, Trans Mountain's Natural Hazard's Management Program was designed to mitigate and avoid many of these potential effects such that they will have little, if any effect on the Project.

7.10.1 Environmental Conditions Not Considered

The following environmental conditions were not considered to have the potential to adversely affect the Project either during construction or operations or both:

- severe weather events including high wind speeds, heavy/persistent precipitation, extreme temperatures and lightning;
- permafrost degradation;
- acid rock drainage (ARD);
- snow avalanche;
- volcanic eruption; and
- tsunami.

7.10.1.1 Severe Weather

High winds could result in the suspension of some construction activities such as topsoil/root zone material salvage, clearing, slash burning and welding. Although this could temporarily delay construction activities, the buried pipeline and above ground facilities will not be adversely affected by high winds. Consequently, no adverse effects on the Project are anticipated due to wind, regardless of wind direction.

Heavy or persistent precipitation could result in the delay of pipeline construction if topsoil/root zone material salvage activities have not been completed or if wet soil conditions create safety or traffic-related problems. Delays in construction due to severe weather conditions are expected to be short in duration, and heavy precipitation will not adversely affect the buried pipeline or above ground facilities. Trans Mountain will monitor the condition of the right-of-way in a timely manner after any heavy rainfall events to look for erosion or washout areas and remediate any damage to protect the integrity of the pipeline. Although it is unlikely, severe persistent precipitation could affect access to above ground facilities during operations.

Extremely cold temperatures create safety hazards for workers. However, delays in construction due to severe weather conditions are expected to be short in duration. Equipment and instruments will be constructed of materials suitable for climate conditions along the corridor, including unusually extreme temperatures, without any risk to pipeline integrity or facility operation. As a result, no adverse effects on the Project are anticipated to result from inclement weather.

Lightning has the potential to affect the power supply and damage buildings or above ground equipment (*i.e.,* block valves, cathodic protection equipment), and ignite wildfires (Section 7.10.4). Buildings and above ground equipment will be grounded in accordance with provincial and National Building Codes to minimize the risk of damage due to lightning. Consequently, the risk of damage to the pipeline and above ground facilities is considered to be low and no changes to the Project are anticipated to result from lightning.

7.10.1.2 Permafrost Degradation

As stated in Section 5.1.1, the proposed pipeline corridor does not encounter any areas of permafrost along any of the proposed pipeline segments in Alberta or BC. No changes to the Project are anticipated to result from permafrost degradation.

7.10.1.3 Acid Rock Drainage

Exposing, excavating or reusing rock during construction can increase the likelihood of ARD from sulphide-bearing rocks due to increased interaction with water and oxygen and larger surface areas relative to undisturbed rock. The effects of the Project on ARD are discussed in Section 7.2.1 Physical and Meteorological Environment. Undisturbed PAG rock is not expected to cause adverse effects on the Project since the pipeline coating will prevent any damage caused by ARD or metal leaching. Further information is provided in the Acid Rock Drainage and Metal Leaching Potential Technical Report of Volume 5C.

7.10.1.4 Snow Avalanche

A snow avalanche is not likely to affect a buried pipeline. One area along the proposed pipeline corridor near the Coquihalla Summit was identified as a potential snow avalanche area; further work related to avalanche zone evaluation is ongoing for construction and operational safety. The additional weight of snow and debris from an avalanche are not anticipated to compromise the structural integrity of the pipe.

7.10.1.5 Volcanic Eruption

The risk of volcanic eruption was brought up as a concern by a participant of the Chilliwack Community Workshop. Ash from volcanoes would not affect the buried pipeline or the structural integrity of above ground facilities, but would likely require some clean up at facilities. of more concern is the seismic activity associated with an eruption. A discussion on seismic hazards is provided in Section 7.10.4.

7.10.1.6 Tsunami

A study of tsunami hazards to the shorelines of North and West Vancouver was conducted in 2005. Computer models of large subaqueous block slides on the western foreslope of the Fraser delta indicate that waves about 2 m high would strike adjacent shorelines shortly after the landslide (Clague and Orwin 2005). Such waves could also occur in the event of seismic activity. However, no evidence of such waves was detected in the geological record, suggesting these large waves, if they occur, are extremely rare. Project design has taken into account a potential tsunami wave occurring at the Westridge Marine Terminal. Waves of this size (*i.e.*, approximately 2 m high) would not adversely affect tankers travelling to and from the terminal, and waves of a size that would affect tankers are considered extremely rare and unlikely. In addition, the location of the Westridge Marine Terminal, being sheltered within Burrard Inlet, lessens the chance of any adverse effects from large waves in the unlikely event of a Pacific tsunami.

7.10.2 Potential Effects and Mitigation Measures

Environmental conditions may have adverse effects on the Project. Natural hazards are naturally occurring events that may have a negative effect on people, the environment or in this case, the Project. Geohazards are a subset of natural hazards which can present severe threats to people, property and natural and built environments, and are generally divided into two classes, slope processes and fluvial processes. Geohazards pose potential threats to pipeline projects during construction with respect to worker safety, and during operations with respect to potential damage to infrastructure and the safety of operating personnel (see Terrain Mapping and Geohazard Inventory Report of Volume 4A). The following environmental conditions were identified by the assessment team as having the potential to adversely affect the Project either during construction or operations or both:

- hydrotechnical hazards (*i.e.,* flooding, scour, bank erosion, debris floods, debris flows and avulsion);
- geotechnical hazards (*i.e.,* rock slope hazards and soil slope hazards);

- seismic hazards (*i.e.,* liquefaction, fault displacement, strong shaking and historic faults);
- wildfires;
- changing climate; and
- sea level rise.

Table 7.10-1 summarizes these potential environmental conditions and provides mitigation measures to reduce the potential effects on the Project.

TABLE 7.10-1

POTENTIAL EFFECTS, MITIGATION MEASURES AND RESIDUAL EFFECTS OF CHANGES TO THE PROJECT CAUSED BY THE ENVIRONMENT

Potential Effect	Project Component	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
1. Hydrotechnical hazards – flooding and erosion caused by hydrotechnical hazards	New pipeline segments Reactivated pipeline segments	Water Quality and Quantity LSA	• Postpone instream water crossing construction if excessive flows or flood conditions are present or anticipated. Ensure that all spoil piles are moved above the anticipated flood line. Resume activities when water levels have subsided or equipment/techniques suitable for conditions are deployed [Section 8.7.1]. • Implement KMC's Emergency Response Plan as well as the Flood and Excessive Flow Contingency Plan in the event of a flood or excessive stream flow (*i.e.,* greater than the seasonally expected normal range based on existing and predicted flow data) during construction [Appendix B]. See also the Soil Erosion and Sediment Control Contingency Plan [Appendix B]. • Implement the Natural Hazards Management Program in KMC's Canadian Integrity Management Program in the event of a hydrotechnical hazard. • Ensure pipeline burial depths at watercourses have taken into consideration flood events and scouring of the bed so that risk to the integrity of the pipeline due to such events is minimal. • Monitor the pipeline depth of cover within watercourses, when warranted, throughout the life of the pipeline. Complete remedial work where warranted to protect pipeline integrity. • Weight the pipeline to prevent buoyancy if poor soils/organic soils are encountered with water in the trench. • Avoid known problem areas. • Employ trenchless crossing techniques. • Use of thicker walled pipe to prevent damage from scouring and erosion.	• Loss of cover over the pipeline may occur at localized areas as a result of an extreme flood and, in rare occasions, result in damage to the pipeline. • Pipeline may become buoyant and float to the surface in flooded areas.
2. Geotechnical hazards – movement of soil and surficial materials	New pipeline segments Reactivated pipeline segments	Soil LSA	• Replace grade material to a stable contour that will approximate the pre-construction contour, except where it is not practical or safe to do so. When replacing sidehill or other graded areas is not practical due to the risk of slope failure, the Lead Activity Inspector, the Lead Environmental Inspector, the Inspector(s), the Construction Manager and a Geotechnical Engineer will discuss to determine an appropriate grade [Section 8.4]. • Assess the erosion hazard prior to the commencement of rough and final clean-up. This assessment, to be conducted by Trans Mountain's Inspector(s) in consultation with the Construction Manager, will consider topography, degree of disturbance, soil erodibility, snow depth, access limitations, timing constraints, and the likely schedule for rough clean-up, final clean-up and seeding. Request assistance in conducting the assessment, if warranted, from Trans Mountain's Environmental Manager, or the Geotechnical, Soil or Reclamation Resource Specialist [Section 8.6.1]. • Implement the Natural Hazards Management Program in KMC's Canadian Integrity Management Program in the event of a geotechnical hazard. • Areas of potential geotechnical instability will be monitored through regular aerial patrols during pipeline operations and remedial action will be promptly conducted, where warranted.	• Rock and soil slope hazards may result in movement of soil and surficial materials over the pipeline that may expose or damage the pipeline.

TABLE 7.10-1 Cont'd

Potential Effect	Project Component	Spatial Boundary	Key Recommendations/Mitigation Measures [EPP Reference][1]	Potential Residual Effect(s)
2. Geotechnical hazards – movement of soil and surficial materials (cont'd)	See above	See above	• Select geotechnically stable route over potentially unstable ones. • Employ shoreline dredging as required to ensure geotechnical stability at the Westridge Marine Terminal.	• See above.
3. Seismic hazards	All	Soil LSA	• Suspend work immediately in the event of a seismic event. Refer to Volume 4B, Section 5.4 for the Emergency Response Plan for further response measures to be taken in the event of seismic activity occurring during construction [Section 7.0]. • Implement KMC's Natural Hazards Management Program. • Further assessments will be conducted along the proposed pipeline corridor to assess site-specific seismic potential. • Pump stations will be equipped with vibration monitoring equipment.	• Seismic activity may damage the pipeline or facilities.
4. Wildfire	All	Wildlife LSA	• Follow the fire suppression measures of the Fire Contingency Plan [Appendix B]. • Implement the Emergency Response Plan and Fire Contingency Plan in Section 3.5 of Volume 4B, as well as KMC's Emergency Response Plan. • See Section 7.9 Accidents and Malfunctions for mitigation measures in the unlikely event that a fire is caused by Project construction activities.	• Depending on the severity, a wildfire could affect the construction schedule or the scheduling of maintenance activities. • Loss of pipeline cover may occur from soil ignition during fire and, in rare occasions, result in pipeline damage.
5. Changing climate	All	Water Quality and Quantity LSA Soil LSA Air Quality RSA / LFV	• Consider the changes to weather trends (*e.g.,* snow pack conditions, timing and intensity of runoff and discharge within watercourses, amount of rainfall) within the Project area when scheduling maintenance activities along the proposed pipeline corridor. • Be prepared for changes in construction plans to accommodate shifts in seasons (*e.g.*, earlier or enhanced snow melt, early thaw, late freezing). • See recommended mitigation measures outlined in potential effects 1 and 4 of this table for potential effects that are potentially exacerbated by changing climate (*e.g.*, altered temperature / hydrologic regimes and wildfires).	• Depending on the type and severity of the change in weather trends, the scheduling of maintenance activities may be affected. • Loss of cover over the pipeline may occur at localized areas as a result of an extreme flood event (see potential effect 1 of this table). • Pipeline may become buoyant and float to the surface in flooded areas (see potential effect 1 of this table). • Loss of pipeline cover may occur from soil ignition during fire, or from wind erosion in areas experiencing drought and, in rare occasions, result in pipeline damage.
6. Sea level rise	Westridge Marine Terminal	Marine Sediment and Water Quality LSA	• Engineering has considered sea level rise in design. • Implement KMC's Natural Hazards Management Program. • Employ shoreline dredging as required to ensure geotechnical stability at the Westridge Marine Terminal.	• Waves over-topping the dock leading to safety hazards, terminal downtime or damage to infrastructure.

Note: 1 Detailed mitigation measures are outlined in the Pipeline EPP (Volume 6B).

7.10.3 Potential Residual Effects

The potential residual effects of the changes to the Project caused by the environment (Table 7.10-1) are:

- loss of cover over the pipeline may occur at localized areas as a result of an extreme flood and, in rare occasions, result in damage to the pipeline;
- pipeline may become buoyant and float to the surface in flooded areas;
- rock and soil slope hazards may result in movement of soil and surficial materials over the pipeline that may expose or damage the pipeline;
- seismic activity may damage the pipeline or facilities;
- depending on the severity, a wildfire could affect the construction schedule or the scheduling of maintenance activities;
- depending on the type and severity of the change in weather trends, the scheduling of maintenance activities may be affected;
- loss of pipeline cover may occur from soil ignition during fire, or from wind erosion in areas experiencing drought and, in rare occasions, result in pipeline damage; and
- waves over-topping the dock leading to safety hazards, terminal downtime or damage to infrastructure.

7.10.4 Significance Evaluation of Potential Residual Effects

Table 7.10-2 provides a summary of the significance evaluation of potential residual effects of the changes to the Project caused by the environment. The rationale used to evaluate the significance of each of the residual effects is provided below.

TABLE 7.10-2

SIGNIFICANCE EVALUATION OF POTENTIAL RESIDUAL EFFECTS OF CHANGES TO THE PROJECT CAUSED BY THE ENVIRONMENT

Potential Residual Effects	Impact Balance	Spatial Boundary	Temporal Context			Magnitude	Probability	Confidence	Significance[1]
			Duration	Frequency	Reversibility				
(a) Loss of cover over the pipeline may occur at localized areas as a result of an extreme flood and, in rare occasions, result in damage to the pipeline.	Negative	Water Quality and Quantity LSA	Immediate to short-term	Accidental	Short to long-term	Low to high	Low	Moderate	Not significant
(b) Pipeline may become buoyant and float to the surface in flooded areas.	Negative	Water Quality and Quantity LSA	Immediate to short-term	Accidental	Short-term	Low to medium	Low	Moderate	Not significant
(c) Rock and soil slope hazards may result in movement of soil and surficial materials over the pipeline that may expose or damage the pipeline.	Negative	Soil LSA	Immediate	Accidental	Short to long-term	Low to high	Low	Moderate	Not significant
(d) Seismic activity may damage the pipeline or facilities.	Negative	Soil LSA	Immediate	Accidental	Short to long-term	Low to high	Low	Moderate	Not significant
(e) Depending on the severity, a wildfire could affect the construction schedule or the scheduling of maintenance activities.	Negative	Wildlife LSA	Immediate to short-term	Accidental	Short-term	Low	Low	High	Not significant

TABLE 7.10-2 Cont'd

Potential Residual Effects	Impact Balance	Spatial Boundary	Temporal Context: Duration	Temporal Context: Frequency	Temporal Context: Reversibility	Magnitude	Probability	Confidence	Significance[1]
(f) Loss of cover over the pipeline may occur at localized areas as a result of an extreme flood and, in rare occasions, result in damage to the pipeline.	Negative	Water Quality and Quantity LSA	Immediate to short-term	Accidental	Short to long-term	Low to high	Low	Moderate	Not significant
(g) Depending on the type and severity of the change in climate trends, the scheduling of maintenance activities may be affected.	Negative	Water Quality and Quantity LSA	Immediate to short-term	Accidental	Short-term	Low	Low	High	Not significant
(h) Loss of pipeline cover may occur from soil ignition during fire, or from wind erosion in areas experiencing drought and, in rare occasions, result in pipeline damage.	Negative	Footprint	Immediate to short-term	Accidental	Short to long-term	Low to high	Low	Moderate	Not significant
(i) Waves over-topping the dock leading to safety hazards, terminal downtime or damage to infrastructure.	Negative	Marine Sediment and Water Quality LSA	Immediate	Occasional	Short-term	Low	Low	Moderate	Not significant

Note: 1 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

Loss of Cover Over the Pipeline or Pipe Buoyancy as a Result of an Extreme Flood Event

An assessment of hydrotechnical hazards along the proposed pipeline corridor was conducted by BGC Engineering Inc. (see the Terrain Mapping and Geohazard Inventory Report of Volume 4A). Types of hydrotechnical hazards identified in the inventory include flooding, scour, bank erosion, debris floods, debris flows and avulsion. Hydrotechnical hazards are present throughout the proposed pipeline corridor, but most were observed in the Interior Plateau (Shuswap) Physiographic Region along the Hargreaves to Darfield Segment.

Concerns regarding flooding were raised in BC by participants of the Abbotsford, Surrey, Coquitlam, Kamloops, Langley, Merritt and Hope Community Workshops, as well as at the Surrey ESA Workshop. Locations where flooding and other hydrotechnical hazards were identified by participants included the Westsyde area near Kamloops, the Nicola River (prone to changing course), the Coquihalla River and Coquihalla Canyon near Hope, Sumas prairie near Abbotsford, the area north of the Fraser River near Coquitlam, and Dewdney Creek near Surrey. Participants at the Surrey ESA Workshop and Langley Community Workshop also raised concerns about the pipe floating to the surface in areas of the Lower Mainland where there could be prolonged flooding.

An extreme flood event, either during construction or operations, could result in a loss of cover over the pipeline along floodplains and in watercourses along the proposed pipeline corridor. Since the proposed pipeline will be carrying oil and will be buried at sufficient depth, the pipeline will not float to the surface even in areas with prolonged flooding. The pipeline will be designed to withstand a 200 year flood event and will have deeper cover in locations with high erosion risk. The potential effects of flooding and associated mitigation vary depending on the timing, location and magnitude of the event. A flood event that occurs immediately prior to the commencement of instream construction at a water crossing could delay construction activities and, in extreme cases, threaten the integrity of the temporary vehicle crossing.

Should flooding occur during construction of a trenched watercourse crossing, the increased flows could exceed the capability of the dams, pumps or flumes used to isolate the construction area or erode onshore spoil piles. In the unlikely event that flooding occurs during instream construction, water quality would likely be somewhat reduced due to an incremental increase in TSS over the slightly elevated TSS levels that are commonly associated with instream construction. The Flood and Excessive Flow Contingency Plan outlined in Appendix B of the Pipeline EPP (Volume 6B) would be implemented to reduce the effects of high water levels during instream construction. The risk of a flood occurring during instream construction is considered to be low since construction is scheduled to avoid peak flows, or if scheduling during peak flows cannot be avoided, a trenchless crossing method would be considered. Specifications for the different methods to be used for buoyancy control will be developed during the detailed engineering and design phase of the Project. In addition, the weather forecast applicable to the watershed for the anticipated crossing construction period can be reviewed immediately prior to commencement of crossing construction enabling the timely implementation of measures to mitigate any concerns.

Instream watercourse crossing construction is proposed after peak flows and the pipeline will be buried deep enough to reduce the potential effects of flooding, as well as associated erosion and scouring. Site-specific design will determine if the pipeline will be weighted down in certain floodplain areas to prevent buoyancy of the pipe. Nevertheless, line patrols during operations will pay particular attention to the bed and banks of watercourse crossings following floods to further ensure the integrity of the pipeline and reduce the potential effects on the aquatic environment. Remedial measures will be taken immediately, where warranted, following receipt of applicable approvals.

In the 60 years that the existing TMPL has been operating, extreme flood events have occurred that resulted in exposure of the pipe that required restoration and the implementation of KMC's Natural Hazards Management Program. River bed cover is monitored after extreme flood events and inspected every 2 years at all crossings regardless of whether a flood event has occurred or not. Trans Mountain uses its Natural Hazards Management Program to monitor and protect against damage to the pipeline from unstable slopes. Established in 1998, this program uses a custom database to document inspections and preventative maintenance work at more than 600 sites along the existing TMPL right-of-way and to schedule future inspection frequency based on risk. Consequently, the probability of a flood affecting the Project and resulting in a significant adverse environmental effect is low. This residual effect is considered to be reversible in the short to long-term and is of low to high magnitude (Table 7.10-2, points [a] and [b]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – effects associated with the loss of cover or pipeline buoyancy as a result of an extreme flood event may extend beyond the construction right-of-way.
- Duration: immediate to short-term – the event causing the loss of cover (*i.e.,* an extreme flood event) or the pipeline to potentially float to the surface is prolonged flooding in floodplain areas, which could last less than two days, or more than two days but less than one year.
- Frequency: accidental – an extreme flood event is rare.
- Reversibility: short to long-term – the effects associated with flooding may take greater than two days but less than one year to reverse the effect. However, in the event of an extreme flooding event where damage to the pipeline may cause a spill, the effects on the environment may take greater than 10 years to reverse, depending on the location.
- Magnitude: low to high – depending on the timing, location and magnitude of the flood event. For most events, damage to the pipe is negligible or minimal (low) whereas if damage was extensive and resulted in a spill, the magnitude of environmental effects could be high depending on the volume of the spill sensitivity of the receiving environment.
- Probability: low – it is unlikely that an extreme flood event will occur that would result in a loss of cover or depth of cover over the proposed pipeline, damage the pipeline or cause the pipe to float to the surface, or exceed the capacity of isolation equipment or erode onshore spoil piles during construction.
- Confidence: moderate – based on the professional experience of the assessment team.

Rock and Soil Slope Hazards May Result in Exposure or Damage to the Pipeline

An assessment of geotechnical hazards along the proposed pipeline corridor was conducted by BGC Engineering Inc. (see the Terrain Mapping and Geohazard Inventory Report of Volume 4A). Types of geotechnical hazards identified in the inventory include rock slope hazards (*e.g.,* rockfall, extremely rapid rockslides, rock debris, rock slumps) and soil slope hazards (*e.g.,* slow earth slides, rapid earth slides, soil raveling [cut slopes] and slow earthflows). Geotechnical hazards are focused in the mountainous regions along the proposed pipeline corridor (*i.e.,* the Interior Plateau [Thompson] and Cascade Mountains Physiographic Regions along the Black Pines to Hope Segment) where there are narrow valleys. The most common type of geotechnical hazard identified is rockfall (natural and cut slopes).

Depending on the location and size of the event, a geotechnical hazard could cause movement of soil and surficial materials in the vicinity of the buried pipeline, which could result in exposure of the pipe or damage to the pipe's integrity. Engineering and design of the pipeline has taken into consideration the potential for geotechnical hazards along the proposed pipeline corridor. In addition, implementation of the mitigation measures (Table 7.10-1) will reduce the risk of a geotechnical hazard adversely affecting the pipeline. Additional information on the potential for an extreme geotechnical event that could damage the pipeline and result in a spill is provided in Volume 7. Areas of potential geotechnical instability will be avoided where practical and monitored through regular aerial patrols during pipeline operations and remedial action will be promptly conducted, where warranted. Through Trans Mountain's Pipeline Integrity Program, aerial surveillances are conducted to monitor for geotechnical events such as landslides at least once a month for every section of the existing TMPL right-of-way and the proposed pipeline will be integrated into this program. Consequently, the probability of a geotechnical hazard affecting the Project and resulting in a significant adverse environmental effect is low. This residual effect is considered to be reversible in the short to long-term and is of low to high magnitude (Table 7.10-2, point [c]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Soil LSA – effects associated with rock or soil slope hazards causing exposure or damage to the pipeline may extend beyond the construction right-of-way.
- Duration: immediate – the event causing exposure or damage to the pipeline (*i.e.,* rock or soil slope hazards) is expected to last less than two days.
- Frequency: accidental – rock or soil slope hazards causing movement of soil or surficial material over the buried pipeline is rare.
- Reversibility: short to long-term – effects associated with exposure or damage to the pipeline as a result of a geotechnical hazard event may take greater than two days but less than one year to reverse the effect. For extreme events where damage to the pipeline results in a spill, the potential environmental effects could take more than 10 years to reverse (*e.g.,* mature vegetation communities).
- Magnitude: low to high – depending on the location and magnitude of the geotechnical hazard event. For some events, the damage to the pipeline may be minimal (low) whereas if damage was extensive and resulted in a spill, the magnitude of environmental effects could be high depending on the volume of the spill and sensitivity of the receiving environment.
- Probability: low – it is unlikely that a rock or soil slope hazard will occur that would result in movement of soil or surficial material in the vicinity of the buried pipeline causing exposure or damage to the pipe.
- Confidence: moderate – based on the professional experience of the assessment team.

Seismic Activity May Damage the Pipeline or Facilities

A desktop study of seismic hazards along the proposed pipeline corridor was conducted by BGC Engineering Inc. (see the Terrain Mapping and Geohazard Inventory Report and Seismic Assessment Desktop Study of Volume 4A). Types of seismic hazards identified in the inventory include liquefaction, seismically induced landsliding, strong shaking and surface fault rupture. The strongest ground motions and largest liquefaction potential are anticipated in the Georgia Depression physiographic region (Hope to

Burnaby Segment). Most seismically induced landslide potential occurs around steep terrain in the Columbia Mountains, Interior Plateau, Cascade Mountains and Georgia Basin (Hargreaves to Darfield and Black Pines to Hope segments). Surface fault rupture may present a hazard in the Georgia Basin and Rocky Mountain Trench regions (between Hargreaves and Rearguard pump stations and in the Hope to Burnaby Segment).

Seismic activity has the potential to affect the integrity of the pipeline and other facilities during the operations phase of the Project. Concerns regarding earthquakes and liquefaction in the Lower Mainland were raised by participants of the Burnaby, Chilliwack, Coquitlam and Surrey Community Workshops. In addition, questions regarding design of the Project and how it will withstand an earthquake were posted in the online forum on Trans Mountain's website.

The commitment of Trans Mountain to reduce the earthquake risk to the existing TMPL is ongoing and includes several investigations and major construction mitigation measures. Further seismic assessments along the proposed pipeline corridor and existing TMPL will include site-specific assessment of: ground-shaking amplification; the potential and anticipated displacement due to liquefaction and landsliding triggered by shaking; and the location, likelihood and anticipated displacement at fault crossings (see Volume 4A for further details).

Through its experience with managing pipelines in the varied terrain of North America, Trans Mountain is very aware of the effect of geologic processes on its pipeline infrastructure. Trans Mountain's Natural Hazards Management Program is one of the key tools for managing geohazard risk to pipeline infrastructure. Trans Mountain is committed to reducing the earthquake risks to the existing TMPL and proactively assess earthquake hazards with consideration of advancements in understanding how pipelines perform during seismic events. Where the pipeline or facilities are determined to be at risk of failure from an earthquake, pipeline infrastructure improvement projects are completed to reduce the risk. Trans Mountain has also prepared an Earthquake Action Protocol to rapidly prioritize locations for pipeline inspection following an earthquake. This protocol includes shutting down and isolating the pipeline in the event of a serious earthquake.

If a seismic event occurs, work will be suspended immediately and the Emergency Response Plan for the Project and KMC's Emergency Response Plan will be implemented for further response measures. The probability of a seismic event affecting the Project and resulting in a significant adverse environmental effect is low. This residual effect is considered to be reversible in the short to long-term and is of low to high magnitude (Table 7.10-2, point [d]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Soil LSA – effects associated with a seismic event may extend beyond the construction right-of-way.
- Duration: immediate – a seismic event lasts less than two days.
- Frequency: accidental – seismic events that have the potential to cause damage to the pipeline resulting in adverse effects on the environment or facilities are rare.
- Reversibility: short to long-term – the effects on the environment resulting from damage to the pipeline or facilities as a result of a seismic event may take greater than two days but less than one year to reverse the effect. For extreme seismic events where the pipeline or facility damage could result in a spill, the potential environmental effects may take more than 10 years to reverse depending on the volume of spill and the sensitivity of the receiving environment.
- Magnitude: low to high – depending on the type, location and severity of the seismic event.
- Probability: low – it is unlikely that a seismic event will occur that would result in damage to the pipeline or facilities.
- Confidence: moderate – based on the professional experience of the assessment team.

Wildfire

A wildfire in the immediate vicinity of the proposed pipeline corridor during the construction phase, although unlikely, could delay construction activities along the affected portions of the proposed pipeline corridor. Participants of the Merritt and Blue River Community Workshops noted that the fire hazard in interior BC can be high in the summer and burning restrictions may be implemented. Construction activities and/or construction-related traffic would be suspended in potentially affected areas if conditions were considered to be unsafe by Trans Mountain's Construction Manager or if requested by the appropriate authority (*i.e.,* AESRD or BC MFLNRO). Contingency measures identified in the Fire Contingency Plan (Appendix B of the Pipeline EPP of Volume 6B) have been prepared to ensure that appropriate and effective procedures and materials are in place in the event of a wildfire during construction of the Project. The short delay of construction activities due to wildfire generally would be considered as having a minor effect on the Project, with the exception of a severe wildfire, which could affect large portions of the proposed pipeline corridor and could delay the resumption of construction activities into another season.

During the operations phase, forest fires are unlikely to adversely affect the buried pipeline other than potential loss of cover from soil combustion or structural changes (point [g] discussed below). However, wildfires could affect above ground facilities and maintenance activities. KMC's Emergency Response Program will be implemented in the event of a wildfire potentially affecting Trans Mountain facilities. The probability of a fire resulting in a significant adverse environmental effect is low (Table 7.10-2, point [e]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Wildlife LSA – a wildfire in the Wildlife LSA could affect access to the construction right-of-way and, consequently, the construction schedule.
- Duration: immediate to short-term – the event affecting the construction schedule (*i.e.,* wildfire) may take more than two days to control depending on the severity of the fire.
- Frequency: accidental – a wildfire affecting aboveground facilities is rare in the Project area.
- Reversibility: short-term – it is likely that construction activities, should they shut-down due to a wildfire, would resume within a year.
- Magnitude: low – the location of the Project is accessible for construction throughout the year and, therefore, could accommodate a delay into another season.
- Probability: low – it is unlikely that a wildfire will occur.
- Confidence: high – based on the professional experience of the assessment team.

Changing Climate – Alteration of Scheduling of Maintenance Activities

Changes to climate during operations of the pipeline may manifest in several ways (*e.g.*, in a long-term increase of annual average temperatures or in the increased occurrence of extreme events). Trans Mountain has been operating for 60 years, over which they have encountered a variety of environmental conditions. It is understood that past environmental conditions may not be representative of conditions under future climate change. For example, extreme events that have occurred only every few decades over the last 60 years might occur more frequently or with greater magnitude during future Project operation. Therefore, Trans Mountain will adaptively manage potential residual effects associated with changing climate through the Natural Hazards Management Program.

Increased snow pack in winter and extended warm temperatures in spring may intensify runoff and alter hydrologic regimes within watercourses, including timing and duration of peak flows. Changes in summer temperatures and rainfall patterns could lead to an increase in wildfires or drought. During operations of the Project, it is expected that Trans Mountain will be adaptive in their management of the pipeline and schedule maintenance activities to accommodate local environmental conditions (*e.g.,* conducting activity in riparian areas during periods of low flow and least risk) and implement the appropriate protection measures to suit local environmental conditions thereby reducing the potential environmental effects. By utilizing adaptive management practices that are responsive to changing conditions, this residual effect is considered to be reversible in the short-term and of low magnitude (Table 7.10-2, point [f]). A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – changing weather trends in the Water Quality and Quantity LSA could affect the maintenance schedule.
- Duration: immediate to short-term – the event affecting the maintenance schedule (*i.e.,* increased intensity and duration of peak flows, wildfires) may last more than two days depending on the severity.
- Frequency: accidental – events causing the change in maintenance schedule (*i.e.,* increased intensity and duration of peak flows, wildfires) are rare in the Project area.
- Reversibility: short-term – it is likely that maintenance activities affected by changes in weather trends could be rescheduled within a year.
- Magnitude: low – most maintenance activities are routine and, consequently, can accommodate a change in schedule.
- Probability: low – Trans Mountain's adaptive management practices would accommodate local ground conditions in light of changing weather trends.
- Confidence: high – based on the professional experience of the assessment team.

Concerns were brought up by participants of the Coquitlam Community Workshop and Surrey ESA Workshop regarding increasing storms, streamflows, and increasing flood intensity and frequency attributed to climate change, and asked how the Project would be designed to withstand such conditions. Project design and engineering of the proposed pipeline is considering climate change and the conditions the pipeline will experience over the length of the operations phase. If an extreme flood event were to occur during construction or operations of the pipeline, mitigation measures would be implemented as discussed in Table 7.10-1. Potential residual effects associated with loss of cover over the pipeline and pipe buoyancy caused by an extreme flood event are discussed above (Table 7.10-2, points [a] and [b]).

Loss of Pipeline Cover From Fire or Drought

In addition to the combustion of woody and plant materials, wildfires may also cause soil to burn. In extreme cases, this could result in a loss of pipeline cover and exposure of the pipeline to damage in a similar manner to flooding described above (Table 7.10-2, point [a]). However, fires can also alter the chemical and structural properties of soil. In particular, increased hydrophobocity can occur, which results in decreased infiltration and increased runoff which can lead to erosion and soil loss (BC Ministry of Agriculture 2013). Similarly, increased drought in dry areas (*e.g.*, Kamloops) associated with climate change contributes to making soil more vulnerable to wind erosion and, therefore, a loss of pipeline cover. However, Trans Mountain's regularly scheduled maintenance and aerial patrols, as well as adaptive management will ensure that these effects are reversible in the short to long-term. A summary of the rationale for all of the significance criteria is provided below.

- Spatial Boundary: Footprint – a wildfire or drought in the construction right-of-way will affect the soil cover immediately over the pipeline.
- Duration: immediate to short-term – the event affecting the soil cover and pipeline integrity is a wildfire or drought event, which could last less than two days, or more than two days but less than one year.
- Frequency: accidental – a wildfire or drought affecting soil cover is rare in the Project area.
- Reversibility: short to long-term – should the pipeline be exposed or damaged due to soil loss from drought or fire, the effect should be reversed within a year. However, in the rare and extreme case where such exposure causes damage to the pipeline and results in a spill, it may take longer than 10 years to reverse the environmental effect.

- Magnitude: low to high – depending on the timing, location and severity of the event, damage to the pipe may be negligible or non-existent, whereas if damage were extensive and resulted in a spill, the effects could be high depending on the amount spilled and the location of occurrence.
- Probability: low – it is unlikely that a wildfire or severe drought will occur that causes exposure or damage to the pipeline.
- Confidence: moderate – based on the professional experience of the assessment team and available literature; however, there are still substantial difficulties in modelling regional future changes in precipitation and the effects on wildfires and droughts.

Waves Over-topping the Dock Leading to Safety Hazards, Terminal Downtime and Damage to Infrastructure

Westridge Marine Terminal dock elevation will be designed to withstand a predicted 0.5 m increase in sea level (as of 2100). Waves associated with this increase as well as associated changes in sediment transport and coastal geomorphology in Burrard Inlet over the next 90 years are difficult to predict. Model parameters required to make such predictions would be highly speculative, and as a result, detailed modelling was not conducted.

Changing weather patterns are also difficult to predict with accuracy and are not expected to have the potential to adversely affect the Project on their own. However, when combined with sea level rise, changing weather patterns could result in larger and more frequent waves. These waves could overtop the dock and lead to short duration adverse effects as a result. The negative effects associated with waves over-topping the dock could include financial losses associated with terminal downtime, ship standby time and increased maintenance and replacement of dock infrastructure.

Based on Trans Mountain's 60 year operating history at the Westridge Marine Terminal within the relatively well protected waters of Burrard Inlet, the engineering considerations related to sea level rise leads to a low probability of waves over-topping the dock. Section 3.4 of Volume 4A includes a description of dock elevation and Figure 3.4.17 of Volume 4A displays the Typical Dolphin and Pile Foundation including elevation above the high water level. Wave energy is expected to dissipate within short-term reversibility. A summary of the rationale for all of the significance criteria is provided below (Table 7.10-2, point [h]).

- Spatial Boundary: Marine Sediment and Water Quality LSA – sea level rise could lead to waves over-topping the dock.
- Duration: immediate – waves from storms would not be expected to continue for more than two days.
- Frequency: occasional – events causing waves to overtop the dock would be sporadic and dependent on weather patterns.
- Reversibility: short-term – it is likely that any dock downtime could be rescheduled within a year.
- Magnitude: low – financial losses caused by terminal downtime or damage to infrastructure are expected to be recoverable.
- Probability: low – design of the dock has taken into consideration 0.5 m sea level rise.
- Confidence: moderate – based on the professional experience of the assessment team.

7.10.5 Summary

As identified in Table 7.10-2, the environmental effects resulting from the environment affecting the Project range from short to long-term reversibility and from low to high magnitude. However, the probability of effects is low. Consequently, it is concluded that the residual effects of the changes to the Project caused by the environment will be not significant.

7.11 Summary of Environmental Effects Assessment

7.11.1 Summary of the Assessment of Potential Effects of the Project on the Environment

This subsection provides an evaluation of combined adverse residual effects and is conducted for those indicators where more than one identified potential adverse residual effect may occur. A discussion of combined effects is included to clarify the overall effect of the Project on the environmental indicator in question and the overall effect of the Project on the environmental element. In addition, the overall effects of the Project on the element are evaluated in consideration of the objectives or goals of applicable land and resource use management plans, municipal development plans (MDPs) and government policies. A summary of the plans considered is provided in Appendix 7.1 and is not considered to be exhaustive.

7.11.1.1 Physical and Meteorological Environment

The evaluation of the effects of the Project on the physical environment element considers the combined effect of applicable Project components on each of the following physical environment indicators: terrain instability; topography; and acid generating and metal leaching rock.

Combined Effects on the Terrain Instability Indicator

The components of the Project which affect the terrain instability indicator include the construction and operations of the proposed pipeline, temporary facilities, pump stations and storage tanks, as well as construction and operations activities associated with the Westridge Marine Terminal. No potential effects were identified for terrain instability resulting from pipeline reactivation activities along the reactivated pipeline segments of Hinton to Hargreaves and Darfield to Black Pines. Furthermore, through the implementation of mitigation measures, no potential residual effects were identified for terrain instability at pump stations, storage tanks and the Westridge Marine Terminal. Therefore, the significance of the combined effects on terrain instability considers the construction and operations of new pipeline segments and temporary facilities and is summarized in Table 7.11.1-1.

The evaluation of the combined effects of the Project on the terrain instability indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all applicable Project components. Overall, the Project has the potential to cause terrain instability as a result of construction and operations activities along new pipeline segments and associated temporary facilities (*i.e.,* temporary access roads and borrow pits) at steep slopes, side hills, trenched watercourse crossings, where blasting is required and where excavation is required at borrow pits, which is considered to have a negative impact balance. Through implementation of industry standard and provincially recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the terrain instability indicator are considered to be of low magnitude (Table 7.11.1-1, point 1[g]). A summary of the rationale for all of the significance criteria of combined effects on terrain instability is provided below.

- Spatial Boundary: Physical Environment LSA – combined effects of the Project on the terrain instability indicator as a result of construction activities may extend beyond the construction workspace.
- Duration: short-term – the event causing combined effects on the terrain instability indicator is construction of the pipeline (*e.g.,* grading and rough clean-up) and temporary facilities (*i.e.,* temporary access roads and borrow sites).
- Frequency: isolated – the event causing combined effects on the terrain instability indicator (*i.e.,* construction of the pipeline and temporary facilities) is confined to a specific period.
- Reversibility: short to medium-term – most areas of terrain instability will be remediated within a year, however, some areas may require a second or third year of remedial effort to fully stabilize.
- Magnitude: low – the implementation of the proposed mitigation measures in addition to detailed engineering design is expected to effectively reduce the severity and extent of combined effects on terrain instability.

- Probability: high – combined effects on terrain instability will likely occur.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on the Topography Indicator

The components of the Project which affect the topography indicator include the construction and operations of the proposed pipeline, temporary facilities, pump stations and storage tanks, as well as construction and operations activities associated with the Westridge Marine Terminal. No potential effects were identified for topography resulting from pipeline reactivation activities.

The evaluation of the combined effects of the Project on the topography indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all applicable Project components (Table 7.11.1-1). Overall, the Project has the potential to alter topography as a result of construction and operations activities along new pipeline segments, at associated temporary facilities (*i.e.,* temporary access roads and borrow pits), pump stations, storage tanks and the Westridge Marine Terminal where grading, blasting or cut slopes are required, which is considered to have a negative impact balance. Through implementation of industry standard and provincially and federally recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the topography indicator are considered to be of low to medium magnitude (Table 7.11.1-1, point 2[g]). A summary of the rationale for all of the significance criteria of combined effects on topography is provided below.

- Spatial Boundary: Physical Environment LSA – combined effects on the topography indicator may extend beyond the construction workspace.
- Duration: short-term – the event causing the combined effects on the topography indicator is construction of Project components.
- Frequency: isolated – the event causing the combined effects on the topography indicator is confined to a specific period (*i.e.,* construction of the various Project components).
- Reversibility: permanent – combined effects on the topography indicator cannot be reversed.
- Magnitude: low to medium – combined effects on the topography indicator are anticipated to be largely mitigated during construction.
- Probability: high – combined effects on topography will likely occur.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on the Acid Generating and Metal Leaching Rock Indicator

The components of the Project which affect the acid generating and metal leaching rock indicator include the construction and operations of the proposed pipeline and temporary facilities. No potential effects were identified for generating and metal leaching rock resulting from construction and operations activities at pump stations, terminals and the Westridge Marine Terminal or pipeline reactivation activities.

The evaluation of the combined effects of the Project on the acid generating and metal leaching rock indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all applicable Project components (Table 7.11.1-1). Overall, the Project has the potential to cause acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching as a result of construction and operations activities along new pipeline segments and at associated temporary facilities (*i.e.,* temporary access roads and borrow pits) where fresh rock cut surfaces are exposed, which is considered to have a negative impact balance. Through implementation of industry standard recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the acid generating and metal leaching rock indicator are considered to be of low magnitude (Table 7.11.1-1, point 3[g]). A summary of the rationale for all of the significance criteria of combined effects on acid generating and metal leaching rock is provided below.

- Spatial Boundary: Physical Environment LSA – any ARD or metal leaching may extend beyond the construction workspace.
- Duration: short-term – the event causing short-term ARD or metal leaching is exposure of bedrock material during construction until mitigation measures are implemented (*e.g.,* covering fresh surfaces, proper storage) or material is removed from site and properly disposed of.
- Frequency: isolated – ARD or metal leaching may be confined to exposed construction materials until covered or removed from site.
- Reversibility: short to medium-term – acidification/contamination of the terrestrial and/or aquatic environment from ARD or metal leaching may result in localized changes to the surrounding environment, which may take longer than one year to fully remediate.
- Magnitude: low – given implementation of the proposed mitigation measures to effectively reduce the potential effect and based on the material composition of identified PAG sites and the limited volume of materials being disturbed and exposed from construction.
- Probability: low – given implementation of the proposed mitigation measures to effectively reduce the potential effect and given the limited volume of materials being disturbed and exposed from construction.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects of the Project on Physical Environment

The evaluation of the combined effects of the Project on the physical environment element considers collectively the assessment of the likely combined effects of the Project on the physical environment indicators. of the physical environment indicators, only two, terrain instability and topography have residual effects that are likely to occur and, consequently, are considered in the evaluation of combined effects of the Project on the physical environment element. The residual effects related to the acid generating and metal leaching rock indicator are of low probability and, therefore, do not form part of the evaluation of the overall effect of the Project on the physical environment.

Local and regional management plans with goals and objectives applicable to the physical environment aid in the assessment of Project-related effects on the physical environment element and influenced the kinds of mitigation strategies developed to reduce or avoid adverse effects. Goals and objectives in the various local and regional management plans relevant to physical environment are listed in Appendix 7.1 and include reducing alteration of topography and natural features, protecting areas of steep slopes, reducing erosion, and avoiding hazardous terrain. Other management plans listed in Appendix 7.1 were reviewed and determined to have no specific goals or objectives related to the physical environment element. With the successful implementation of the mitigation measures, and since Project activities will be conducted in accordance with all applicable federal, provincial and municipal legislation, the Project is not expected to interfere with goals and objectives of the various management plans relevant to the physical environment as listed in Appendix 7.1.

The combined effects of the Project on physical environment indicators are considered to be of low magnitude with the implementation of the proposed mitigation measures to reduce effects on terrain instability and alteration of topography (Table 7.11.1-1, point 4[a]). A summary of the rationale for all of the significance criteria of combined effects on the physical environment indicators is provided below.

- Spatial Boundary: Physical Environment LSA – combined effects of the Project on the physical environment indicators may extend beyond the construction workspace.
- Duration: short-term – the event causing the combined effects of the Project on physical environment indicators is construction of the various Project components.

- Frequency: isolated – the event causing the combined effects of the Project on the physical environment indicators is confined to a specific period (*i.e.,* construction of the pipeline and temporary facilities).
- Reversibility: short-term to permanent – combined effects of the Project on the physical environment indicators may be reversed following reclamation or remediation or may not be reversed where permanent alteration or environmental damage has occurred.
- Magnitude: low – combined effects of the Project on the physical environment indicators are not expected to interfere with goals and objectives of management plans relevant to the physical environment indicators.
- Probability: high – based on data pertinent to the Project area and the professional experience of the assessment team.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

<u>Summary</u>

As identified in Table 7.11.1-1, there are no situations where there is a high probability of occurrence of a permanent or long-term environmental effect on physical environment of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the environmental effects of the Project on physical environment indicators will be not significant.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

7.11.1.2 Soil and Soil Productivity

The evaluation of the effects of the Project on soil and soil productivity considers the combined effect of applicable Project components on each of the following indicators: soil productivity; soil degradation; bedrock and stone disposal; and soil contamination.

Combined Effects on the Soil Productivity Indicator

The components of the Project which affect the soil productivity indicator include the construction and operations of the proposed pipeline, temporary facilities, pump stations and storage tanks, the Westridge Marine Terminal and pipeline reactivation activities.

The evaluation of the combined effects of the Project on the soil productivity indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all Project components (Table 7.11.1-2). Overall, the Project has the potential to decrease soil productivity through admixing of topsoil/root zone material and subsoil caused by disturbance to soil, including grading, topsoil/root zone material salvage, trenching, backfilling and storage activities. The combined effect is considered to have a negative impact balance. Through implementation of industry standard and provincially recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the soil productivity indicator are considered to be of low magnitude and reversible in the short to long-term (Table 7.11.1-2, point 1[g]). A summary of the rationale for all of the significance criteria of combined effects on soil productivity is provided below.

- Spatial Boundary: Footprint – combined effects on the soil productivity indicator are confined to the area of disturbance associated with each Project component.
- Duration: short-term – the events causing combined effects on the soil productivity indicator are construction and operations (*i.e.,* maintenance activities) of the various Project components which are limited to any one year during the operations phase.
- Frequency: periodic – the events causing combined effects on the soil productivity indicator (*i.e.,* construction and maintenance-related activities) will occur intermittently but repeatedly over the assessment period.
- Reversibility: short to long-term – combined effects on the soil productivity indicator are anticipated to take less than 10 years to reverse but could take more than 10 years to reverse where there is admixing of undesirable lower subsoils with upper subsoils during construction of the proposed pipeline.
- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the combined effects on soil productivity.
- Probability: high – the construction and operations of the Project will disturb soils and affect soil productivity.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil productivity.

Combined Effects on the Soil Degradation Indicator

The components of the Project which affect the soil degradation indicator include the construction and operations of the proposed pipeline, temporary facilities, pump stations, storage tanks, Westridge Marine Terminal and pipeline reactivation activities.

The evaluation of the combined effects of the Project on the soil degradation indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all Project components (Table 7.11.1-2). Overall, the Project has the potential to degrade soil structure through compaction and rutting, erosion and pulverization caused by disturbance to soil, including grading, topsoil/root zone material salvage, trenching, backfilling and storage activities. The combined effect is considered to have a negative impact balance. Through implementation of industry standard and provincially recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the soil degradation indicator are considered to be of low magnitude and reversible in the short to medium-term (Table 7.11.1-2, point 2[g]). A summary of the rationale for all of the significance criteria of combined effects on soil degradation is provided below.

- Spatial Boundary: Footprint – combined effects on the soil degradation indicator are confined to the area of disturbance associated with each Project component.
- Duration: short-term – the events causing combined effects on the soil degradation indicator are construction of the various Project components; and maintenance-related activities which are limited to any one year during the operations phase.
- Frequency: periodic – the events causing combined effects on the soil degradation indicator (*i.e.,* construction and maintenance-related activities) will occur intermittently but repeatedly over the assessment period.
- Reversibility: short to medium-term – given the implementation of mitigation measures during construction and, if necessary, the application of soil amendments post-construction, some effects contributing to combined effects on the soil degradation indicator are expected to reverse over the short-term (*e.g.,* degradation of soil structure due to compaction and rutting or pulverization), while other effects such as surface erosion and deep compaction may take a few years to reverse.

- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the combined effects on the soil degradation indicator.
- Probability: high – the construction and operations of the Project will disturb soils and potentially affect soil structure resulting in soil degradation.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil degradation.

Combined Effects on the Bedrock and Stone Disposal Indicator

The bedrock and stone disposal indicator will only be affected by construction and operations of the pipeline and, therefore, the combined effects of the pipeline on bedrock and stone disposal is considered to represent the combined effects of the Project on this indicator. The significance evaluation for bedrock and stone disposal is provided in Section 7.2.2.6 and summarized in Table 7.11.1-2, point 3(g).

Combined Effects on the Soil Contamination Indicator

No potential residual effects associated with any Project components were identified related to the soil contamination indicator. Consequently, no further assessment is warranted.

Combined Effects of the Project on Soil and Soil Productivity

The evaluation of the combined effects of the Project on the soil and soil productivity indicators considers collectively the assessment of the combined effects of the Project on the soil productivity, soil degradation and bedrock and stone disposal indicators.

Local and regional management plans containing goals and objectives applicable to soil and soil productivity aid in the assessment of Project-related effects on the soil and soil productivity indicators. Goals and objectives contained within the various local and regional management plans relevant to soil and soil productivity are listed in Appendix 7.1. For example, through the implementation of the mitigation measures for each soil and soil productivity indicator, it is believed that the Project meets the goal of the Parkland County Municipal Development Plan, Bylaw No. 37-2007 (Parkland County 2007) to conserve agricultural lands for agricultural and related uses. Through the implementation of mitigation measures, the Project also aligns with the goal of the Regional Growth Strategy for the FVRD to promote the reclamation of lands back to agricultural use, where appropriate (FVRD 2004). Other management plans listed in Appendix 7.1 were reviewed and determined to have no specific goals or objectives related to the soil and soil productivity indicators.

Effects on soils resulting from pipeline projects are well understood. Results of post-construction environmental monitoring programs of large pipelines in western Canada demonstrate that the effects on soil productivity can be effectively mitigated (TERA 2009a,b, 2011a,b,c, 2012a, 2013a,b). Mitigation based on land use, construction season, soil characterization and contingency plans are in place for wet/thawed soil conditions, soil erosion and soil/sod pulverization (Volumes 6B, 6C and 6D). With the successful implementation of the mitigation measures, and since Project activities will be conducted in accordance with all applicable provincial and municipal legislation (including those related to the Agricultural Land Reserve), the Project is not expected to interfere with goals and objectives of the various management plans relevant to soil and soil productivity as listed in Appendix 7.1.

The combined effects of the Project on soil and soil productivity are considered to be low and reversible in the short to long-term (Table 7.11.1-2, point 5[a]). A summary of the rationale for all of the significance criteria of combined effects on the soil and soil productivity indicators is provided below.

- Spatial Boundary: Footprint – combined effects of the Project on the soil and soil productivity indicators are confined to the area of disturbance associated with each Project component.
- Duration: short-term – the events causing combined effects of the Project on the soil and soil productivity indicators are construction of the various Project components; and maintenance-related activities which are limited to any one year during the operations phase.

- Frequency: periodic – the events causing combined effects of the Project on the soil and soil productivity indicators (*i.e.,* construction and maintenance-related activities) occur intermittently but repeatedly over the assessment period.
- Reversibility: short to long-term – combined effects of the Project on the soil and soil productivity indicators are generally expected to reverse in the short to medium-term for effects associated with soil degradation and bedrock and stone disposal for most of the Project components; however, long-term effects on soil productivity are anticipated at pump stations, storage tanks and Westridge Marine Terminal where topsoil/root zone material will be stored for the life of the operational pipeline.
- Magnitude: low – the implementation of the proposed mitigation measures is expected to effectively reduce the combined effects of the Project on soil and soil productivity.
- Probability: high – each Project component is predicted to affect one or more soil indicators.
- Confidence: high – based on a good understanding by the assessment team of cause-effect relationships between pipeline construction and soil productivity.

Summary

As identified in Table 7.11.1-2, there are no situations where there is a high probability of occurrence of a permanent or long-term environmental effect on soil and soil productivity of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the environmental effects of the Project on soil and soil productivity indicators will be not significant.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

7.11.1.3 Water Quality and Quantity

The evaluation of the effects of the Project on the water quality and quantity indicators considers the combined effect of applicable Project components on each of the following water quality and quantity indicators: surface water quality; surface water quantity; groundwater quality; and groundwater quantity.

Combined Effects on the Surface Water Quality Indicator

The components of the Project which affect the surface water quality indicator include the construction and operations of the proposed pipeline, temporary facilities, pump stations and storage tanks. No potential effects were identified for surface water quality resulting from construction and operations activities at the Westridge Marine Terminal. In addition, although combined effects on surface water quality from pipeline reactivation were identified, they are considered to be unlikely to occur and, consequently, are not included in the evaluation of combined effects of the Project on the surface water quality indicator.

The evaluation of the combined effects of the Project on the surface water quality indicator considers collectively the assessment of the likely combined effects on this indicator from construction and operations of all applicable Project components (Table 7.11.1-3). Overall, the Project has the potential to reduce surface water quality as a result of construction and operations activities in and around waterbodies and watercourses due to increased suspended sediment and erosion of banks and approach slopes, which is considered to have a negative impact balance. Through implementation of industry standard and provincially recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the surface water quality indicator are considered to be of low to medium magnitude (Table 7.11.1-3, point 1[g]). A summary of the rationale for all of the significance criteria of combined effects on surface water quality is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – combined effects on the surface water quality indicator may extend beyond the construction or operations workspace to the predicted ZOI.
- Duration: short-term – the events causing the combined effects on the surface water quality indicator are construction and operations (*e.g.,* maintenance activities) of various Project components.
- Frequency: isolated to occasional – the events causing the combined effects on the surface water quality indicator are generally confined to the construction period but may occur intermittently and sporadically during the operations phase.
- Reversibility: immediate to medium-term – the events causing combined effects on the surface water quality indicator may be reversible immediately (*e.g.,* increased suspended sediment due to upstream construction at select watercourses) or may take more than a year to return to existing conditions (*e.g.,* to re-establish vegetation on approach slopes and banks).
- Magnitude: low to medium – combined effects on the surface water quality indicator are anticipated to be largely mitigated during construction.
- Probability: high – based on data pertinent to the Project area and the professional experience of the assessment team.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on the Surface Water Quantity Indicator

The components of the Project which affect the surface water quantity indicator include the construction and operations of the proposed pipeline, temporary facilities, pump stations and storage tanks, Westridge Marine Terminal, as well as pipeline reactivation activities.

The evaluation of the combined effects of the Project on the surface water quantity indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all Project components (Table 7.11.1-3). Overall, the Project has the potential to reduce surface water quantity as a result of construction and operations activities in and around waterbodies and watercourses through alteration of natural surface drainage patterns and disruption of natural streamflow from instream activities, which is considered to have a negative impact balance. Through implementation of industry standard and provincially recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the surface water quantity indicator are considered to be of low to medium magnitude (Table 7.11.1-3, point 2[g]). A summary of the rationale for all of the significance criteria of combined effects on surface water quality is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – combined effects on the surface water quantity indicator may extend beyond the construction or operations workspace to the predicted ZOI.
- Duration: short-term – the events causing the combined effects on the surface water quantity indicator are construction and operations (*e.g.,* maintenance activities) of various Project components.
- Frequency: isolated to occasional – the events causing the combined effects on the surface water quantity indicator are generally confined to the construction period but may occur intermittently and sporadically during into the operations phase.
- Reversibility: short-term to permanent – the events causing combined effects on the surface water quantity indicator may be reversible in the short to medium-term for the pipeline, temporary facilities and power lines where it may take more than one year to restore natural drainage patterns and long-term (*i.e.,* greater than 10 years) to permanent for above ground facilities depending whether natural drainage patterns can be restored following decommissioning and abandonment.
- Magnitude: low to medium – combined effects on the surface water quantity indicator are anticipated to be largely mitigated during construction.

- Probability: high – based on data pertinent to the Project area and the professional experience of the assessment team.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Combined Effects on the Groundwater Quality Indicator

An evaluation of the combined effects of the Project on the groundwater quality indicator considers collectively the assessment of the likely combined effects on this indicator from construction and operations of all applicable Project components. Although residual effects related to groundwater quality were identified for the pipeline, pump stations and proposed tanks components only, none of the effects were considered likely to occur. Consequently, an evaluation of combined effects of the Project on the groundwater quality indicator is not warranted.

Combined Effects on the Groundwater Quantity Indicator

An evaluation of the combined effects of the Project on the groundwater quantity indicator considers collectively the assessment of the likely combined effects on this indicator from construction and operations of all applicable Project components. Although residual effects related to groundwater quantity were identified for the pipeline and the Westridge Marine Terminal components only, none of the effects were considered likely to occur. Consequently, an evaluation of combined effects of the Project on the groundwater quality indicator is not warranted.

Combined Effects of the Project on Water Quality and Quantity

The evaluation of the combined effects of the Project on the water quality and quantity indicators considers collectively the assessment of the combined effects of the Project that are likely to occur (*i.e.,* surface water quality and surface water quantity). Since no potential effects were identified for the groundwater quality or quantity indicators, these were not considered in the overall effects of the Project on water quality and quantity.

Local and regional management plans containing goals and objectives applicable to water quality and quantity aided in the assessment of Project-related effects on the water quality and quantity indicators and influenced the mitigation developed to reduce or avoid adverse effects. For example, through the implementation of the mitigation measures for each water quality and quantity indicator, it is believed that the Project meets the goals of both the Parkland County Integrated Community Sustainability Plan (Parkland County 2011) to minimize water use and contamination, and the Strathcona County Municipal Development Plan (Strathcona County 2007) to reduce consumption of fresh water resources from lakes, rivers and aquifers. Through implementation of mitigation measures, the Project also aligns with the policy of the Thompson-Nicola Regional District (TNRD) Regional Growth Strategy (TNRD 2000) to protect the quality and quantity of water of the region's lakes, rivers, streams and groundwater sources, as well as an action of the FVRD Regional Growth Strategy to protect the region’s potable surface and groundwater resources by supporting water conservation and stormwater management measures (FVRD 2004). Additional goals and objectives contained in the various local and regional management plans relevant to water quality and quantity are listed in Appendix 7.1. Other management plans listed in Appendix 7.1 were reviewed and determined to have no specific goals or objectives related to the water quality and quantity indicators.

The results of the post-construction environmental monitoring programs of large pipeline projects in western Canada demonstrate that the effects of pipeline and facility construction on surface water quality can be effectively mitigated (TERA 2009a,b, 2011a,b,c, 2012a, 2013a,b). With the successful implementation of the mitigation measures in Volumes 6B, 6C and 6D, and since Project activities will be conducted in accordance with all applicable federal, provincial and municipal legislation, the combined effects of the Project on water quality and quantity are considered to be of low to medium magnitude (Table 7.11.1-3, point 5[a]) and, furthermore, are not expected to interfere with goals and objectives of the various management plans relevant to water quality and quantity as listed in Appendix 7.1. A summary of the rationale for all of the significance criteria of combined effects of the Project on the water quality and quantity indicators is provided below.

- Spatial Boundary: Water Quality and Quantity LSA – the combined effects of the Project on the water quality and quantity indicators may extend beyond the construction or operations workspace to the predicted ZOI.
- Duration: short-term - the events causing the combined effects of the Project on the water quality and quantity indicators are construction and operations (*e.g.,* maintenance activities) of various Project components.
- Frequency: isolated to occasional - the events causing the combined effects of the Project on the water quality and quantity indicators are generally confined to the construction period but may occur intermittently and sporadically during into the operations phase.
- Reversibility: short-term to permanent – the events causing combined effects on the water quality and quantity indicators will vary, where certain residual effects may be reversed shortly after construction, while others may not fully be reversed until reclamation and post-construction environmental monitoring or, in some cases, decommissioning and abandonment. At certain aboveground facilities, such as the Burnaby Terminal, full restoration of natural drainage patterns may not be possible following decommissioning and abandonment.
- Magnitude: low to medium – the combined effects of the Project on the water quality and quantity indicators are anticipated to be largely mitigated during construction and operations.
- Probability: high – based on data pertinent to the Project area and the professional experience of the assessment team.
- Confidence: high – based on data pertinent to the Project area and the professional experience of the assessment team.

Summary

As identified in Table 7.11.1-3, there are no situations where there is a high probability of occurrence of a permanent or long-term environmental effect on water quality and quantity of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the environmental effects of the Project on water quality and quantity indicators will be not significant.

TABLE 7.11.1-3

SIGNIFICANCE EVALUATION OF THE PROJECT ON WATER QUALITY AND QUANTITY

Potential Effect	Impact Balance	Spatial Boundary[1]	Temporal Context			Magnitude	Probability	Confidence	Significance[2]
			Duration	Frequency	Reversibility				
1. Water Quality and Quantity – Surface Water Quality									
1(a) Combined effects from pipeline.	Negative	LSA	Short-term	Isolated to occasional	Immediate to medium-term	Low to medium	High	High	Not significant
1(b) Combined effects from temporary facilities.	Negative	LSA	Immediate to short-term	Isolated	Immediate to short-term	Low	High	High	Not significant

3(g)	Combined effects of the Project on the groundwater quality indicator.	Although residual effects were identified for select Project components, none were considered to be likely, therefore, an evaluation of combined effects was not deemed necessary.								
4.	Water Quality and Quantity – Groundwater Quantity									
4(a)	Combined effects from pipeline.	Although residual effects were identified, none were considered to be likely, therefore, an evaluation of combined effects was not deemed necessary.								
4(b)	Combined effects from temporary facilities.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
4(c)	Combined effects from pump station activities.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
4(d)	Combined effects from tanks.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
4(e)	Combined effects from Westridge Marine Terminal.	Although residual effects were identified, none were considered to be likely, therefore, an evaluation of combined effects was not deemed necessary.								
4(f)	Combined effects from pipeline reactivation.	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A	N/A
4(g)	Combined effects of the Project on the groundwater quantity indicator.	Although residual effects were identified for select Project components, none were considered to be likely, therefore, an evaluation of combined effects was not deemed necessary.								
5.	Combined Effects of the Project on Water Quality and Quantity									
5(a)	Combined effects of the Project on the water quality and quantity indicators (1[g] and 2[g]).	Negative	LSA	Short-term	Isolated to occasional	Short-term to permanent	Low to medium	High	High	Not significant

Notes: 1 LSA = Water Quality and Quantity LSA.

2 <u>Significant Residual Environmental Effect</u>: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

7.11.1.4 Air Emissions

The evaluation of the effects of the Project on the air emissions indicators considers the combined effect of applicable Project components on each of the following air emissions indicators: CACs and VOCs; formation of secondary particulate matter and ozone; and H_2S and mercaptans.

Combined Effects on the Primary Emissions of CACs and VOCs Indicator

The components of the Project, which affect the primary emissions of CACs and VOCs indicator, include the construction and operations of the proposed pipeline, temporary facilities, pump stations and storage tanks, the Westridge Marine Terminal and pipeline reactivation. Residual effects varied between the construction and operations phases and were dependent on the type of activities. The significance of the combined effects on CACs and VOCs from construction and operations of the Project is summarized in Table 7.11.1-4.

The evaluation of the combined effects of the Project on the primary emissions of CACs and VOCs indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all Project components. Overall, the Project has the potential to cause CACs and VOCs increases during construction and operations, which are considered to have a negative impact balance. Through implementation of industry standard recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the primary emissions of CACs and VOCs indicator are considered to be of medium magnitude. Although predicted concentrations are expected to exceed ambient air quality objectives for some pollutants in some areas (see Air Quality and GHG Technical Report Volume 5C) these exceedances are not due to the Project, would occur without the Project, and the Project makes only a small contribution to these maximum ambient concentrations (Table 7.11.1-4, point 1[g]). A summary of the rationale for all of the significance criteria of combined effects on primary emissions of CACs and VOCs is provided below.

- Spatial Boundary: Air Quality RSA – changes to ambient ground-level concentrations of CACs and VOCs from construction and operation are expected to occur within the Air Quality RSA.
- Duration: long-term – the events resulting in emissions of CACs and VOCs occur short-term for construction but long-term during Project operation.
- Frequency: continuous – fugitive VOC emissions occur continuously over the Project life.
- Reversibility: long-term – emissions of CACs and VOC will extend long-term over the Project life and reverse within a few days at the end of the Project.
- Magnitude: medium – the increase in ambient ground-level concentrations of CACs and VOC is expected to be small and not exceed regulatory limits, but in some cases are expected to approach regulatory limits.
- Probability: high – storage tank construction will result in emissions of CACs.
- Confidence: moderate – residual effects assessment is based on a good understanding of cause-effect relationships between construction and air emissions but in some cases reliant on information from previous projects.

Combined Effects on Formation of Secondary Particulate Matter and Ozone Indicator

The components of the Project which affect the formation of secondary particulate matter and ozone indicator include the construction and operations of the storage tanks and Westridge Marine Terminal. Residual effects varied between the construction and operations phases and were dependant on the type of activities. The significance of the combined effects on formation of secondary particulate matter and ozone from construction and operations of the Project is summarized in Table 7.11.1-4.

The evaluation of the combined effects of the Project on the formation of secondary particulate matter and ozone indicator considers collectively the assessment of the combined effects on this indicator from construction and operations of all applicable Project components. Overall, the Project has the potential to cause secondary particulate matter and ozone increases during construction and operations which is considered to have a negative impact balance. Through implementation of industry standard recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the formation of secondary particulate matter and ozone indicator are considered to be of medium magnitude (Table 7.11.1-4, point 2[g]). A summary of the rationale for all of the significance criteria of combined effects on formation of secondary particulate matter and ozone is provided below.

- Spatial Boundary: LFV – changes to ambient ground-level concentrations of secondary PM and ozone and visibility reductions are expected to occur within the LFV photochemical modelling domain.
- Duration: long-term – the combined effects on secondary particulate matter and ozone are expected to occur for the operational life of the Project and, therefore, are considered long-term.
- Frequency: continuous – the combined effects on secondary particulate matter and ozone (*i.e.*, mostly from VOC fugitive precursor emissions and combustion products causing formation of ozone) occur continuously during Westridge Marine Terminal operations.
- Reversibility: long-term – combined effects on secondary particulate matter and ozone reflect fugitive emissions of VOCs during operations at the terminals which will extend for the operational life of the terminal. Combined emissions are reversible as the increase in ambient particulate matter and ozone will cease when the facility is decommissioned.
- Magnitude: medium – the increase in ambient ground-level concentrations of particulate matter and ozone and reduction in visibility are expected to be small relative to existing conditions, but for some areas within the LFV, ambient ground-level concentrations of ozone might approach Canadian Ambient Air Quality Standards.
- Probability: high – an increase in Project-related product storage, handling, and loading as well as equipment use will result in precursor emissions, which contribute to secondary PM and ozone formation and reduced visibility.
- Confidence: moderate – based on a good understanding of cause-effect relationships between the Project, air emissions, and atmospheric reactions; however, there is uncertainty with respect to non-Project emissions, and atmospheric chemical reactions are complex.

Combined Effects on Hydrogen Sulphide and Mercaptans Indicator

The components of the Project which affect the H_2S and mercaptans indicator include the operations of the storage tanks and Westridge Marine Terminal. The significance of the combined effects on H_2S and mercaptans from operations of the Project is summarized in Table 7.11.1-4.

The evaluation of the combined effects of the Project on the H_2S and mercaptans indicator considers collectively the assessment of the combined effects on this indicator from the operations of all applicable Project components. Overall, the Project has the potential to cause increases in H_2S and mercaptans during operations which is considered to have a negative impact balance. Through implementation of industry standard recommended mitigation measures during the operations phase of the Project, the combined effects of the Project on the H_2S and mercaptans indicator are considered to be of low magnitude and are expected to meet applicable ambient air quality objectives (Table 7.11.1-4, point 3[g]). A summary of the rationale for all of the significance criteria of combined effects on formation of secondary particulate matter and ozone is provided below.

- Spatial Boundary: Air Quality RSA – changes to ambient ground-level concentrations of H_2S and mercaptans are expected to occur within the Air Quality RSA.
- Duration: long-term – emissions of H_2S and mercaptans and subsequent changes to ambient ground-level concentrations are expected to occur for the life of the Project and, therefore, are considered long-term.

- Frequency: continuous – emissions of H_2S and mercaptans will occur continuously throughout the operations phase.
- Reversibility: long-term – emissions of H_2S and mercaptans during operations at the terminals will extend over the operational life of the terminal.
- Magnitude: low – the increase in ambient ground-level concentrations of H_2S and mercaptans is expected to cause nuisance odour at some locations and times but is not expected to approach regulatory limits.
- Probability: high – an increase in Project volumes of product being handled and stored will result in an increase in emissions of H_2S and mercaptans.
- Confidence: moderate – based on a good understanding of cause-effect relationships but used assumptions for equipment based on previous projects pending Project design.

Combined Effects on Air Emissions

All components of the Project affect air quality. These include: the construction and operations of the proposed pipeline, temporary facilities, pump stations and storage tanks, as well as construction and operations activities associated with the Westridge Marine Terminal and pipeline reactivation. Residual effects from these activities varied between the construction and operations phases and were dependant on the type of activities. The significance of the combined effects on air emissions from construction and operations of the Project is summarized in Table 7.11.1-4.

For the residual effects assessments of air emissions, regulatory limits (*e.g.* ambient air quality objectives and standards) were taken into consideration. Exceedances of ambient air quality objectives are predicted within the air quality RSA; however, the Project is not responsible for these exceedances and the Project's contribution to these exceedances is not considered significant for the purpose of this assessment. In addition to numerical regulatory limits, other references to air quality that were found in land and resource use management plans, municipal development plans, and government policies are briefly described here.

A number of documents identify the goal to maintain existing good air quality (District of Clearwater 2012, Government of Alberta 2003, Township of Langley 1979) or improve air quality (City of Abbotsford 2005, City of Burnaby 1998, City of Coquitlam 2001a,b, City of Edmonton 2010, City of Spruce Grove 2010, Metro Vancouver 2011, RDFFG 2006). The Thompson-Nicola Regional District Regional Growth Strategy (TNRD 2000) encourages the development and adoption of policies that contribute to the reduction or prevention of air pollution.

More stringently, Robson Valley wants to reduce and work to eliminate pollution of air (BC ILMB 1999), and Nicola Valley (TNRD 2011e) requires that new industrial developments should not emit substances that would have a detrimental effect on air quality. Given the limited duration of Project-related construction emissions and the localized nature of operation emissions, the Project is not expected to negatively affect these plans. In addition, the mitigation measures proposed in this assessment support these general plans and strategies.

The City of Edmonton (2010) describes a general framework for policies and initiatives on emission reductions, but does not provide any specific targets, goals or objectives. Strathcona County (2007) plans to work with those authorities having jurisdiction, to assist in identifying existing and potential air quality concerns and to mitigate or eliminate these issues. It further encourages industrial associations, the federal government, and the provincial government to collaboratively expand and implement a regional airshed monitoring system. A similar cooperative approach with appropriate jurisdictions to protect air quality is proposed by the FVRD (2004). The Government of Alberta (2003) also emphasizes the importance of expanded monitoring efforts to provide a comprehensive picture of regional air quality. Adequate siting of industrial facilities to minimize dust, smoke, or odour issues for nearby residences and other land uses is are required by the Town of Stony Plain (2005), Parkland County (2012), the Village of Wabamun (2010), and the Town of Hinton (1998). PMV (2010) is working on the implementation of an air emissions strategic plan that encompasses new technologies to reduce air emissions. Minimizations and restriction of slash burning and open burning are required in BC ILMB (1999) and City of Chilliwack (1998).

The evaluation of the combined effects of the Project on air emissions considers collectively the assessment of the combined effects on the primary emissions of CACs and VOCs, secondary particulate matter and ozone, and H_2S and mercaptan indicators from the construction and operations of all applicable Project components. Overall, the Project has the potential to cause increased air emissions during construction and operations which is considered to have a negative impact balance. Through implementation of industry standard recommended mitigation measures during the construction and operations phases of the Project, the combined effects of the Project on the air emission indicators are considered to be of medium magnitude (Table 7.11.1-4, point 4[a]). A summary of the rationale for all of the significance criteria of combined effects of the Project on the air emission indicators is provided below.

- Spatial Boundary: LFV and Air Quality RSA – changes to ambient ground-level concentrations of secondary $PM_{2.5}$ and ozone as well as changes to visibility are expected to occur within the LFV, which includes the Air Quality RSA. Outside the LFV, changes are expected to occur in the Air Quality RSA.
- Duration: long-term – emissions of fugitive VOCs, H_2S, and mercaptans and subsequent changes to ambient ground-level concentrations are expected to occur for the life of the Project and, therefore, are considered long-term.
- Frequency: continuous – emissions of fugitive VOCs, H_2S, and mercaptans will occur continuously throughout the operations phase.
- Reversibility: long-term – emissions air contaminants during operations at the terminals will extend over the operational life of the terminal.
- Magnitude: medium – the increase in ambient ground-level concentrations of some CAC is expected to approach but not exceed regulatory limits.
- Probability: high – increased emissions of air contaminants will occur and will result in increased ambient concentrations, secondary formation of ozone and $PM_{2.5}$, and reductions in visibility.
- Confidence: moderate – based on a good understanding of cause-effect relationships, but in some cases, information from previous projects had to be used.

Summary

As identified in Table 7.11.1-4, there are no situations where there is a high probability of occurrence of a permanent or long-term environmental effect on air emissions of high magnitude that cannot be technically or economically mitigated. Consequently, it is concluded that the environmental effects of the Project on air emissions indicators will be not significant.

2 Significant Residual Environmental Effect: A high probability of occurrence of a permanent or long-term residual effect of high magnitude that cannot be technically or economically mitigated.

7.11.1.5 Greenhouse Gas Emissions

The evaluation of the effects of the Project on GHG emissions considers the combined effect of applicable Project components on each of the following GHG emission indicators: emissions of CO_2, CH_4 and N_2O; and effects on overall climate change.

The evaluation of the combined effects of the Project on each of the above GHG emission indicators are noted in Table 7.2.5-8 and the accompanying discussion in Section 7.2.5.6 provides an evaluation of the significance of the individual effects on these indicators. The rationale for the significance evaluation of the combined indicators is provided below.

Combined Effects of the Project on GHG Emissions and Overall Climate Change

The evaluation of the combined effects of the Project on GHG emissions considers collectively the assessment of the combined effects of the Project on the following indicators: emissions of CO_2, CH_4 and N_2O; and effects on overall climate change.
